Contents

1 Configuration.....	1
1.1 IP Routing.....	1
1.1.1 Basic IP Routing Configuration.....	1
1.1.1.1 Basic IP Routing Description.....	1
1.1.1.1.1 Overview of Basic IP Routing.....	1
1.1.1.1.2 Understanding IP Routing.....	1
1.1.1.1.3 Application Scenarios for IP Routing.....	25
1.1.1.1.4 Appendix List of Port Numbers of Common Protocols.....	28
1.1.1.1.5 Terminology for IP Routing.....	29
1.1.1.2 Basic IP Routing Configuration.....	30
1.1.1.2.1 Overview of Basic IP Routing.....	30
1.1.1.2.2 Configuration Precautions for Basic IP Routing.....	31
1.1.1.2.3 Configuring the Router ID.....	31
1.1.1.2.4 Configuring IPv4 Multi-Topology.....	32
1.1.1.2.5 Configuring IPv6 Multi-Topology.....	33
1.1.1.2.6 Configuring IPv4 FRR.....	33
1.1.1.2.7 Configuring IPv6 FRR.....	37
1.1.1.2.8 Configuring Route Recursion to the Default Route.....	40
1.1.1.2.9 Configuring the Device to Advertise Host Routes of Directly Connected Interfaces.....	41
1.1.1.2.10 Configuring Association Between Direct Routes and a VRRP Group.....	42
1.1.1.2.11 Configuring an IPv4 Direct Route to Respond to L3VE Interface Status Changes After a Delay.....	45
1.1.1.2.12 Configuring an IPv6 Direct Route to Respond to L3VE Interface Status Changes After a Delay.....	48
1.1.1.2.13 Configuring the Association Between the IPv4 Direct Route and PW Status.....	50
1.1.1.2.14 Configuring the Association Between the IPv6 Direct Route and PW Status.....	52
1.1.1.2.15 Configuring AGGs to Load Balance Downstream Traffic.....	55
1.1.1.2.16 Configuring the Advertisement of Public Network IPv4 ARP Vlink Direct Routes.....	57
1.1.1.2.17 Configuring the Advertisement of IPv6 NDP Vlink Direct Routes on the Public Network.....	59
1.1.1.2.18 Configuring the Device to Filter ARP or ND Entries When Advertising VPN Vlink Direct Routes.....	61
1.1.1.2.19 Configuring the Association Between IPv4 Direct Routes and IPsec Instance Status.....	63
1.1.1.2.20 Configuring Route or Tunnel Recursion Suppression in Case of Flapping.....	65
1.1.1.2.21 Maintaining IP Routes.....	66
1.1.1.2.22 Configuration Examples for IP Routing Basis.....	71

1.1.2 IPv4 Static Route Configuration.....	102
1.1.2.1 Static Routes Description.....	102
1.1.2.1.1 Overview of Static Routes.....	102
1.1.2.1.2 Understanding Static Routes.....	102
1.1.2.2 IPv4 Static Route Configuration.....	114
1.1.2.2.1 Overview of IPv4 Static Routes.....	114
1.1.2.2.2 Configuration Precautions for IPv4 static route.....	115
1.1.2.2.3 Configuring IPv4 Static Routes.....	118
1.1.2.2.4 Configuring IPv4 Floating Static Routes.....	124
1.1.2.2.5 Configuring Association between LDP and Static Routes.....	125
1.1.2.2.6 Configuring IPv4 Static Route Detection.....	128
1.1.2.2.7 Configuring FRR for IPv4 Static Routes.....	139
1.1.2.2.8 Configuration Examples for IPv4 Static Routes.....	140
1.1.3 IPv6 Static Route Configuration.....	184
1.1.3.1 IPv6 Static Route Configuration.....	184
1.1.3.1.1 Overview of IPv6 Static Routes.....	184
1.1.3.1.2 Configuration Precautions for IPv6 Static Route.....	184
1.1.3.1.3 Configuring IPv6 Static Routes.....	184
1.1.3.1.4 Configuring IPv6 Floating Static Routes.....	189
1.1.3.1.5 Configuring IPv6 Static Route Detection.....	190
1.1.3.1.6 Configuring FRR for IPv6 Static Routes.....	199
1.1.3.1.7 Configuration Examples for IPv6 Static Routes.....	201
1.1.4 OSPF Configuration.....	238
1.1.4.1 OSPF Description.....	239
1.1.4.1.1 Overview of OSPF.....	239
1.1.4.1.2 Understanding OSPF.....	241
1.1.4.2 OSPF Configuration.....	332
1.1.4.2.1 Overview of OSPF.....	332
1.1.4.2.2 Configuration Precautions for OSPF.....	335
1.1.4.2.3 Configuring Basic OSPF Functions.....	342
1.1.4.2.4 Configuring OSPF on the NBMA or P2MP Network.....	354
1.1.4.2.5 Adjusting OSPF Route Selection.....	360
1.1.4.2.6 Controlling OSPF Routing Information.....	369
1.1.4.2.7 Adjusting the OSPF Network Convergence Speed.....	385
1.1.4.2.8 Configuring OSPF Delay Advertisement.....	396
1.1.4.2.9 Configuring OSPF Neighbor Relationship Flapping Suppression.....	398
1.1.4.2.10 Disabling OSPF Interface Flapping Suppression.....	401
1.1.4.2.11 Configuring Routing Loop Detection for Routes Imported into OSPF.....	402
1.1.4.2.12 Configuring OSPF Flush Source Tracing.....	402
1.1.4.2.13 Configuring an OSPF Hostname.....	404
1.1.4.2.14 Configuring an OSPF Stub Area.....	405
1.1.4.2.15 Configuring an NSSA.....	407

1.1.4.2.16 Configuring OSPF Local MT.....	410
1.1.4.2.17 Configuring an OSPF Sham Link.....	412
1.1.4.2.18 Configuring BFD for OSPF.....	415
1.1.4.2.19 Configuring OSPF IP FRR.....	421
1.1.4.2.20 Configuring OSPF GR Helper.....	427
1.1.4.2.21 Improving OSPF Network Security.....	429
1.1.4.2.22 Configuring the Network Management Function of OSPF.....	433
1.1.4.2.23 Configuring Whitelist Session-CAR for OSPF.....	434
1.1.4.2.24 Configuring Micro-Isolation CAR for OSPF.....	435
1.1.4.2.25 Configuring the Threshold Alarm Function for the Number of OSPF Neighbors.....	436
1.1.4.2.26 Maintaining OSPF.....	436
1.1.4.2.27 Configuring OSPF Multi-Area Adjacency.....	439
1.1.4.2.28 Configuration Examples for OSPF.....	451
1.1.5 OSPFv3 Configuration.....	545
1.1.5.1 OSPFv3 Description.....	545
1.1.5.1.1 Introduction to OSPFv3.....	545
1.1.5.1.2 Understanding OSPFv3.....	546
1.1.5.2 OSPFv3 Configuration.....	608
1.1.5.2.1 OSPFv3 Overview.....	608
1.1.5.2.2 Configuration Precautions for OSPFv3.....	609
1.1.5.2.3 Configuring Basic OSPFv3 Functions.....	610
1.1.5.2.4 Configuring OSPFv3 Attributes on Different Types of Networks.....	618
1.1.5.2.5 Adjusting OSPFv3 Route Selection.....	622
1.1.5.2.6 Controlling OSPFv3 Routing Information.....	626
1.1.5.2.7 Configuring OSPFv3 Delay Advertisement.....	639
1.1.5.2.8 Disabling DN Bit Setting in OSPFv3 LSAs.....	641
1.1.5.2.9 Configuring OSPFv3 Neighbor Relationship Flapping Suppression.....	643
1.1.5.2.10 Configuring Routing Loop Detection for Routes Imported to OSPFv3.....	646
1.1.5.2.11 Disabling OSPFv3 Interface Flapping Suppression.....	647
1.1.5.2.12 Configuring OSPFv3 Flush Source Tracing.....	647
1.1.5.2.13 Configuring an OSPFv3 Hostname.....	649
1.1.5.2.14 Configuring an OSPFv3 Stub Area.....	650
1.1.5.2.15 Configuring an OSPFv3 NSSA.....	652
1.1.5.2.16 Configuring OSPFv3 IP FRR.....	654
1.1.5.2.17 Configuring BFD for OSPFv3.....	658
1.1.5.2.18 Configuring OSPFv3 Authentication.....	663
1.1.5.2.19 Configuring OSPFv3 Fast Convergence.....	672
1.1.5.2.20 Configuring the OSPFv3 GR Helper.....	678
1.1.5.2.21 Configuring OSPFv3 to Report Network Topology Information to BGP-LS.....	680
1.1.5.2.22 Improving OSPFv3 Network Stability.....	680
1.1.5.2.23 Configuring the Network Management Function of OSPFv3.....	685
1.1.5.2.24 Whitelist Session-CAR for OSPFv3.....	686

1.1.5.2.25 Configuring Micro-Isolation CAR for OSPFv3.....	687
1.1.5.2.26 Configuring the Threshold Alarm Function for the Number of OSPFv3 Neighbors.....	688
1.1.5.2.27 Maintaining OSPFv3.....	688
1.1.5.2.28 Configuration Examples for OSPFv3.....	691
1.1.6 RIP Configuration.....	749
1.1.6.1 RIP Description.....	749
1.1.6.1.1 Overview of RIP.....	749
1.1.6.1.2 Understanding RIP.....	750
1.1.6.2 RIP Configuration.....	759
1.1.6.2.1 Overview of RIP.....	759
1.1.6.2.2 Configuration Precautions for RIP.....	760
1.1.6.2.3 Configuring Basic RIP Functions.....	760
1.1.6.2.4 Preventing Routing Loops.....	766
1.1.6.2.5 Adjusting RIP Route Selection.....	769
1.1.6.2.6 Controlling RIP Routing Information.....	774
1.1.6.2.7 Configuring RIP Fast Convergence.....	782
1.1.6.2.8 Configuring Dynamic BFD for RIP.....	787
1.1.6.2.9 Configuring Static BFD for RIP.....	790
1.1.6.2.10 Configuring OPS to Control Packet Sending and Receiving on RIP Interfaces.....	791
1.1.6.2.11 Improving the RIP Network Security.....	793
1.1.6.2.12 Configuring RIP Network Management.....	803
1.1.6.2.13 Maintaining RIP.....	803
1.1.6.2.14 Configuration Examples for RIP.....	805
1.1.7 RIPng Configuration.....	828
1.1.7.1 RIPng Description.....	828
1.1.7.1.1 Overview of RIPng.....	828
1.1.7.1.2 Understanding RIPng.....	829
1.1.7.2 RIPng Configuration.....	835
1.1.7.2.1 Overview of RIPng.....	835
1.1.7.2.2 Configuration Precautions for RIPng.....	836
1.1.7.2.3 Configuring Basic RIPng Functions.....	836
1.1.7.2.4 Controlling the Sending and Receiving of RIPng Packets.....	839
1.1.7.2.5 Preventing Routing Loops.....	841
1.1.7.2.6 Adjusting RIPng Route Selection.....	844
1.1.7.2.7 Controlling RIPng Routing Information.....	847
1.1.7.2.8 Configuring RIPng Timers.....	853
1.1.7.2.9 Configuring IPsec Authentication for RIPng.....	854
1.1.7.2.10 Maintaining RIPng.....	856
1.1.7.2.11 RIPng Configuration Examples.....	857
1.1.8 IS-IS Configuration.....	866
1.1.8.1 IS-IS Description.....	866
1.1.8.1.1 Overview of IS-IS.....	866

1.1.8.1.2 Understanding IS-IS.....	866
1.1.8.1.3 Application Scenarios for IS-IS.....	940
1.1.8.2 IS-IS Configuration.....	941
1.1.8.2.1 Overview of IS-IS.....	942
1.1.8.2.2 Configuration Precautions for IS-IS.....	942
1.1.8.2.3 Configuring Basic IPv4 IS-IS Functions.....	945
1.1.8.2.4 Configuring IPv4 IS-IS Route Selection.....	959
1.1.8.2.5 Configuring IPv4 IS-IS to Interact with Other Routing Protocols.....	971
1.1.8.2.6 Adjusting the IPv4 IS-IS Route Convergence Speed.....	976
1.1.8.2.7 Configuring an IS-IS Multi-Instance Process.....	986
1.1.8.2.8 Enabling the Advertisement of IPv4 Delay Information.....	988
1.1.8.2.9 Configuring Interface MSD Advertisement (IPv4).....	989
1.1.8.2.10 Configuring an IS-IS Process to Advertise IPv4 Packet Loss Rates	990
1.1.8.2.11 Configuring LFA Link Attribute Advertisement.....	992
1.1.8.2.12 Configuring IS-IS Extended Prefix Attribute Advertisement (IPv4).....	993
1.1.8.2.13 Configuring Static BFD for IS-IS.....	994
1.1.8.2.14 Configuring Dynamic BFD for IS-IS.....	996
1.1.8.2.15 Configuring Track BFD for IS-IS.....	1000
1.1.8.2.16 Configuring IS-IS IPv4 MT to Isolate Multicast Services from Unicast Services.....	1001
1.1.8.2.17 Configuring IPv4 IS-IS Route Summarization.....	1005
1.1.8.2.18 Configuring IS-IS Auto FRR.....	1006
1.1.8.2.19 Configuring Basic IPv6 IS-IS Functions.....	1009
1.1.8.2.20 Configuring IPv6 IS-IS Route Selection.....	1020
1.1.8.2.21 Configuring IPv6 IS-IS to Interact with Other Routing Protocols.....	1032
1.1.8.2.22 Adjusting the IPv6 IS-IS Route Convergence Speed.....	1037
1.1.8.2.23 Enabling the Advertisement of IPv6 Delay Information.....	1047
1.1.8.2.24 Configuring an IS-IS Process to Advertise IPv6 Packet Loss Rates	1049
1.1.8.2.25 Configuring IS-IS Extended Prefix Attribute Advertisement (IPv6).....	1050
1.1.8.2.26 Configuring IS-IS Neighbor Relationship Flapping Suppression.....	1052
1.1.8.2.27 Disabling IS-IS Interface Flapping Suppression.....	1054
1.1.8.2.28 Configuring Routing Loop Detection for Routes Imported into IS-IS.....	1054
1.1.8.2.29 Configuring IS-IS Purge Source Tracing.....	1055
1.1.8.2.30 Configuring Dynamic BFD for IPv6 IS-IS.....	1056
1.1.8.2.31 Configuring Track BFD for IPv6 IS-IS.....	1060
1.1.8.2.32 Configuring IS-IS IPv6 MT to Isolate Multicast Services from Unicast Services.....	1061
1.1.8.2.33 Configuring IS-IS MT to Isolate IPv4 Services from IPv6 Services.....	1065
1.1.8.2.34 Configuring IPv6 IS-IS Route Summarization.....	1069
1.1.8.2.35 Configuring IPv6 IS-IS Auto FRR.....	1070
1.1.8.2.36 Configuring an IS-IS Link Group.....	1073
1.1.8.2.37 Configuring IS-IS Local MT.....	1075
1.1.8.2.38 Improving IS-IS Network Security.....	1078
1.1.8.2.39 Configuring Whitelist Session-CAR for IS-IS.....	1084

1.1.8.2.40 Configuring Micro-Isolation CAR for IS-IS.....	1085
1.1.8.2.41 Maintaining IS-IS.....	1085
1.1.8.2.42 IS-IS Configuration Examples.....	1089
1.1.9 BGP Configuration.....	1172
1.1.9.1 BGP Description.....	1172
1.1.9.1.1 Overview of BGP.....	1172
1.1.9.1.2 Understanding BGP.....	1175
1.1.9.2 BGP Configuration.....	1303
1.1.9.2.1 BGP Overview.....	1303
1.1.9.2.2 Configuration Precautions for BGP.....	1305
1.1.9.2.3 Configuring Basic BGP Functions.....	1317
1.1.9.2.4 Configuring the Format of BGP 4-Byte AS Numbers.....	1325
1.1.9.2.5 Configuring BGP Route Attributes.....	1326
1.1.9.2.6 Configuring BGP Routing Policies.....	1344
1.1.9.2.7 Configuring BGP XPL.....	1367
1.1.9.2.8 Configuring BGP Route Summarization.....	1370
1.1.9.2.9 Configuring BGP to Generate a Summary Default Route.....	1372
1.1.9.2.10 Configuring a BGP Peer Group.....	1373
1.1.9.2.11 Configuring Distributed BGP Peers.....	1377
1.1.9.2.12 Configuring BGP Parallelization.....	1377
1.1.9.2.13 Configuring a BGP Route Reflector.....	1378
1.1.9.2.14 Configuring a BGP Confederation.....	1384
1.1.9.2.15 Configuring BGP Community Attributes.....	1385
1.1.9.2.16 Configuring the BGP Large-Community Attribute.....	1390
1.1.9.2.17 Configuring Prefix-based BGP ORF.....	1392
1.1.9.2.18 Adjusting the BGP Network Convergence Speed.....	1393
1.1.9.2.19 Configuring a Dynamic BGP Peer Group.....	1402
1.1.9.2.20 Configuring a BGP Device to Send a Default Route to Its Peer.....	1403
1.1.9.2.21 Configuring a Device to Advertise BGP Supernet Unicast Routes to BGP Peers.....	1405
1.1.9.2.22 Configuring BGP Load Balancing.....	1406
1.1.9.2.23 Configuring BGP LSP Load Balancing.....	1413
1.1.9.2.24 Configuring a BGP SR LSP.....	1414
1.1.9.2.25 Configuring Path MTU Auto Discovery.....	1418
1.1.9.2.26 Configuring BGP Route Recursion to the Default Route.....	1421
1.1.9.2.27 Configuring BGP Next Hop Recursion Based on a Route-Policy.....	1422
1.1.9.2.28 Configuring AIGP value on a Route-Policy.....	1423
1.1.9.2.29 Configuring BGP Add-Path.....	1427
1.1.9.2.30 Configuring the POPGO Function.....	1429
1.1.9.2.31 Configuring the Device to Perform the Label Pop-go Action for Packets Carrying the Label Added to Each Received Non-labeled Unicast Route.....	1430
1.1.9.2.32 Configuring conversion from BGP IPv4 Unicast Routes to Labeled Routes.....	1432
1.1.9.2.33 Configuring BFD for BGP.....	1434
1.1.9.2.34 Configuring BGP Peer Tracking.....	1439

1.1.9.2.35 Configuring BGP Auto FRR.....	1440
1.1.9.2.36 Configuring Delayed Response to BGP Next Hop Recursion Changes.....	1441
1.1.9.2.37 Setting a Specified BGP Peer or Each Peer in a Peer Group as an Independent Update Peer-Group.....	1444
1.1.9.2.38 Configuring a Delay in Releasing Obtained Labels in a BGP LSP FRR Switchover Scenario.....	1445
1.1.9.2.39 Configuring the Route Server Function.....	1447
1.1.9.2.40 Configuring the BGP GR Helper.....	1448
1.1.9.2.41 Enabling GR for BGP Peers.....	1449
1.1.9.2.42 Configuring BGP G-Shut.....	1451
1.1.9.2.43 Configuring BGP Best-external.....	1452
1.1.9.2.44 Configuring BMP.....	1453
1.1.9.2.45 Configuring BGP Route Dampening.....	1458
1.1.9.2.46 Configuring Suppression on BGP Peer Flapping.....	1460
1.1.9.2.47 Configuring Flapping Suppression Involved in BGP Next Hop Recursion.....	1461
1.1.9.2.48 Configuring BGP-LS.....	1462
1.1.9.2.49 Configuring the Entropy Label Capability for a BGP LSP.....	1466
1.1.9.2.50 Configuring BGP RPD.....	1468
1.1.9.2.51 Configuring the Capability of Creating MPLS Local IFNET Tunnels for BGP Peers.....	1470
1.1.9.2.52 Configuring the YANG Management Mode of BGP.....	1472
1.1.9.2.53 Improving BGP Security.....	1474
1.1.9.2.54 Configuring BGP Extensions.....	1489
1.1.9.2.55 Configuring BGP Multi-Instance.....	1490
1.1.9.2.56 Maintaining BGP.....	1491
1.1.9.2.57 BGP Route Selection Rules.....	1501
1.1.9.2.58 Configuration Examples for BGP.....	1580
1.1.10 BGP4+ Configuration.....	1740
1.1.10.1 BGP4+ Configuration.....	1740
1.1.10.1.1 Overview of BGP4+.....	1740
1.1.10.1.2 Configuration Precautions for BGP4+.....	1743
1.1.10.1.3 Configuring Basic BGP4+ Functions.....	1743
1.1.10.1.4 Controlling Route Advertisement.....	1750
1.1.10.1.5 Controlling BGP4+ Route Selection.....	1756
1.1.10.1.6 Configuring BGP4+ Routing Policies.....	1768
1.1.10.1.7 Configuring BGP4+ XPL.....	1786
1.1.10.1.8 Configuring BGP4+ Route Recursion to the Default Route.....	1788
1.1.10.1.9 Configuring BGP4+ to Generate Locator Routes.....	1789
1.1.10.1.10 Configuring BGP4+ Load Balancing.....	1790
1.1.10.1.11 Configuring BGP4+ to Generate a Summary Default Route.....	1796
1.1.10.1.12 Configuring BGP4+ Connection Parameters.....	1797
1.1.10.1.13 Configuring BGP4+ RR.....	1802
1.1.10.1.14 Configuring a BGP4+ Confederation.....	1808
1.1.10.1.15 Configuring BGP4+ Community Attributes.....	1809
1.1.10.1.16 Configuring Prefix-based BGP4+ ORF.....	1814

1.1.10.1.17 Configuring the BGP4+ Add-Path Function.....	1815
1.1.10.1.18 Configuring BFD for BGP4+.....	1817
1.1.10.1.19 Configuring BGP4+ Auto FRR.....	1819
1.1.10.1.20 Setting a Specified BGP4+ Peer or Each Peer in a Peer Group as an Independent Update Peer-Group.....	1820
1.1.10.1.21 Configuring the Route Server Function.....	1821
1.1.10.1.22 Configuring the BGP4+ GR Helper.....	1822
1.1.10.1.23 Configuring BMP.....	1823
1.1.10.1.24 Enabling GR for BGP4+ Peers.....	1827
1.1.10.1.25 Configuring BGP4+ Route Dampening.....	1828
1.1.10.1.26 Configuring Suppression on BGP4+ Peer Flapping.....	1830
1.1.10.1.27 Configuring Flapping Suppression Involved in BGP4+ Next Hop Recursion.....	1831
1.1.10.1.28 Configuring BGP-LS (IPv6).....	1832
1.1.10.1.29 Configuring BGP SAVNET (IPv6).....	1836
1.1.10.1.30 Configuring BGP4+ Security.....	1840
1.1.10.1.31 Configuring BGP4+ 6PE.....	1853
1.1.10.1.32 Enabling the Device to Recurse BGP IPv6 Unicast Routes to LSPs.....	1858
1.1.10.1.33 Maintaining BGP4+.....	1860
1.1.10.1.34 Configuration Examples for BGP4+.....	1866
1.1.11 Routing Policy Configuration.....	1893
1.1.11.1 Routing Policy Description.....	1893
1.1.11.1.1 Overview of Routing Policy.....	1893
1.1.11.1.2 Understanding Routing Policies.....	1895
1.1.11.1.3 Application Scenarios for Routing Policies.....	1910
1.1.11.2 Routing Policy Configuration.....	1913

1 Configuration

1.1 IP Routing

NOTE

Properly plan route configurations to prevent network problems caused by route loops. For details, see Layer 3 Routing Loop Prevention for Routers ([Carrier users](#)/[Enterprise users](#)).

1.1.1 Basic IP Routing Configuration

1.1.1.1 Basic IP Routing Description

1.1.1.1.1 Overview of Basic IP Routing

Definition

As a basic concept on data communication networks, routing is the process of packet relaying or forwarding, and the process provides route information for packet forwarding.

Purpose

During data forwarding, routers, routing tables, and routing protocols are indispensable. Routing protocols are used to discover routes and contribute to the generation of routing tables. Routing tables store the routes discovered by various routing protocols, and routers select routes and implement data forwarding.

1.1.1.1.2 Understanding IP Routing

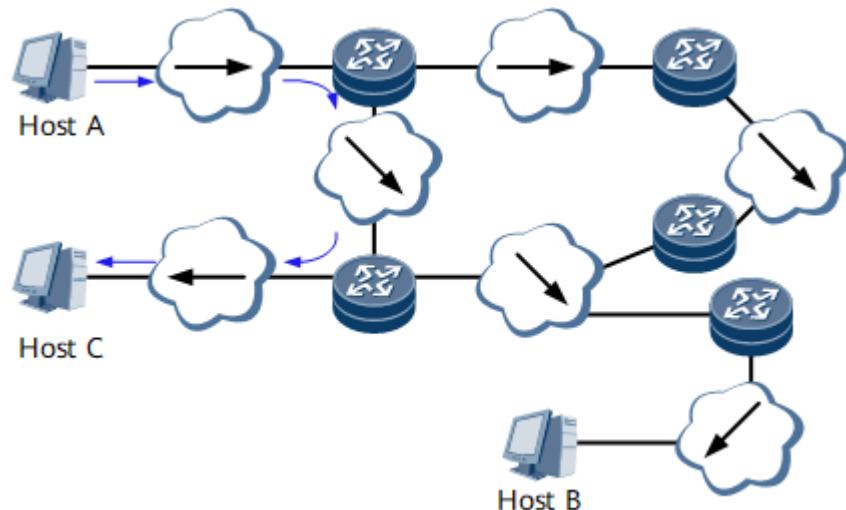

Routers

On the Internet, network connection devices control network traffic and ensure data transmission quality on networks. Common network connection devices include hubs, bridges, switches, and routers.

As a standard network connection device, a router is used to select routes and forward packets. Based on the destination address in the received packet, a router selects a path to send the packet to the next router. The last router is responsible for sending the packet to the destination host. In addition, a router can select an optimal path for data transmission.

For example, in **Figure 1-1**, traffic from Host A to Host C needs to pass through three networks and two routers. The hop count from a router to its directly connected network is zero. The hop count from a router to a network that the router can reach through another router is one. The rest can be deduced by analogy. If a router is connected to another router through a network, a network segment exists between the two routers, and they are considered adjacent on the Internet. In **Figure 1-1**, the bold arrows indicate network segments. The routers do not need to know about the physical link composition of each network segment.

Figure 1-1 Network segment and hop count

Network sizes may vary greatly, and the actual lengths of network segments vary as well. Therefore, you can set a weighted coefficient for the network segments of each network and then measure the cost of a route based on the number of network segments.

A route with the minimal network segments is not necessarily optimal. For example, a route passing through three high-speed Local Area Network (LAN) network segments may be a better choice than one passing through two low-speed Wide Area Network (WAN) network segments.

Routing Protocols

Routing protocols are rules used by routers to discover routes, add routes, and maintain routing tables for packet forwarding.

Routing Tables

A router searches a routing table for routes, and each router maintains at least one routing table.

Routing tables store the routes discovered by various routing protocols. Based on the generation method, routes in a routing table consist of the following types:

- Routes discovered by link layer protocols, which are also called interface routes or direct routes
- Static routes configured by the network administrator
- Dynamic routes that are discovered by dynamic routing protocols

Routing Table Types

Each router maintains a local core routing table, and each routing protocol maintains its own routing table.

- Protocol routing table

A protocol routing table stores routing information discovered by the protocol. A routing protocol can import and advertise routes generated by other routing protocols. For example, if a router that runs Open Shortest Path First (OSPF) needs to use OSPF to advertise direct routes, static routes, or Intermediate System to Intermediate System (IS-IS) routes, the router needs to import these routes into the OSPF routing table.

- Local core routing table

A local core routing table stores protocol routes and optimal routes and selects routes based on the priorities of routing protocols and costs of routes. You can run the **display ip routing-table** command to view the local core routing table of a router.

NOTE

Each router that supports Layer 3 virtual private network (L3VPN) maintains a management routing table (local core routing table) for each VPN instance.

Contents in the Routing Table

On the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X, the **display ip routing-table** command displays brief information about the routing table.

```
<HUAWEI> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table: Public
Destinations : 8      Routes : 8

Destination/Mask Proto Pre Cost Flags NextHop      Interface
          0.0.0.0/0  Static 60  0    D   10.1.4.2    GigabitEthernet1/0/0
          10.1.4.0/30 OSPF   10  0    D   10.1.4.1    GigabitEthernet1/0/0
          10.1.4.1/32 Direct  0   0    D   127.0.0.1  InLoopBack0
          10.1.4.2/32 OSPF   10  0    D   10.1.4.2    GigabitEthernet1/0/0
          127.0.0.0/8 Direct  0   0    D   127.0.0.1  InLoopBack0
          127.0.0.1/32 Direct  0   0    D   127.0.0.1  InLoopBack0
          127.255.255.255/32 Direct 0   0    D   127.0.0.1 InLoopBack0
          255.255.255.255/32 Direct 0   0    D   127.0.0.1 InLoopBack0
```

A routing table contains the following key entries:

- Destination: indicates the destination IP address or the destination network address of an IP packet.

- Mask: indicates the network mask. The network mask and the destination address are used together to identify the address of the network segment where the destination host or router resides.
 - The address of the network segment where the destination host or router resides can be calculated using after the AND operation on the destination address and network mask. For example, if the destination address is 1.1.1.1 and the mask is 255.255.255.0, the address of the network segment where the host or the router resides is 1.1.1.0.
 - The mask, which consists of several consecutive 1s, can be expressed either in dotted decimal notation or by the number of consecutive 1s in the mask. For example, the length of the mask 255.255.255.0 is 24, and therefore, the mask can also be expressed as 24.
- Protocol: indicates the name of a routing protocol.
- Pre: indicates the priority of a route that is added to the IP routing table. If multiple routes have the same destination but different next hops or outbound interfaces or these routes are static routes or discovered by different routing protocols, the one with the highest priority (the smallest value) is selected as the optimal route. For the route priority of each routing protocol, see [Table 1-1](#).
- Cost: indicates the route cost. When multiple routes to the same destination have the same priority, the route with the smallest cost is selected as the optimal route.

NOTE

The Preference is used during the selection of routes discovered by different routing protocols, whereas the Cost is used during the selection of routes discovered by the same routing protocol.

- Flags:
 - Route flag:
 - R: indicates a recursive route.
 - D: indicates a route that is downloaded to the FIB.
 - T: indicates a route whose next hop belongs to a VPN instance.
 - B: indicates a black-hole route.
 - Next hop: indicates the IP address of the next router through which an IP packet passes.
 - Interface: indicates the outbound interface that forwards an IP packet.

Based on the destination addresses, routes can be classified into the following types:

- Network segment route: The destination is a network segment.
- Host route: The destination is a host.

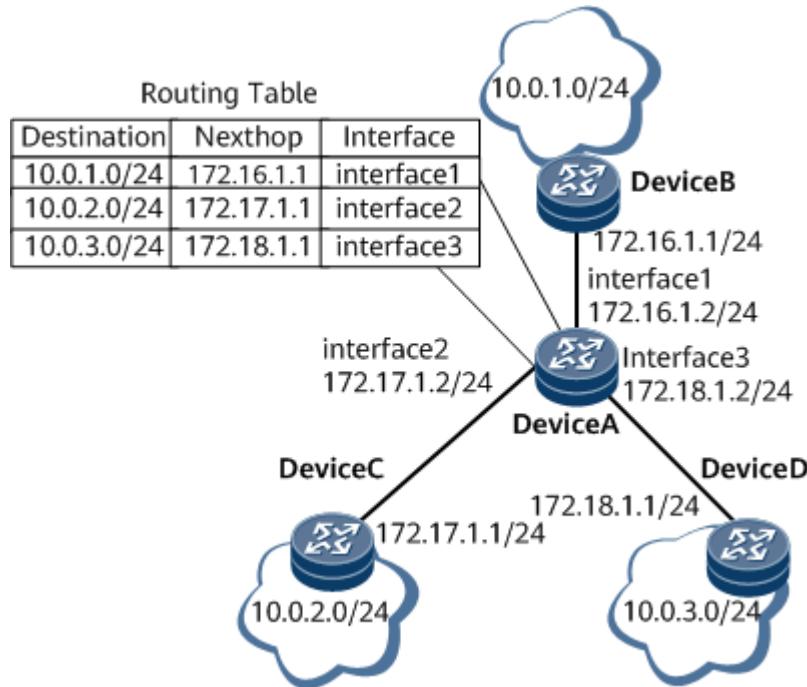

In addition, based on whether the destination is directly connected to the router, route types are as follows:

- Direct route: The router is directly connected to the destination network.
- Indirect route: The router is indirectly connected to the destination network.

Setting a default route can reduce the number of routing entries in the routing table. When a router cannot find a route in the routing table, the router uses the default route (destined for 0.0.0.0/0) to send packets.

In [Figure 1-2](#), Device A is connected to three networks, and therefore, it has three IP addresses and three outbound interfaces. [Figure 1-2](#) shows the routing table on Device A.

Figure 1-2 Routing table

Route Recursion

Routes can be used to forward traffic only when they have directly connected next hops. However, this condition may not be met when routes are generated.

Therefore, the system needs to search for the directly connected next hops and corresponding outbound interfaces, and this process is called route recursion. In most cases, BGP routes, static routes, and UNRs do not have directly connected next hops, and route recursion is required.

For example, the next hop IP address of a BGP route is the IP address of a non-directly connected peer's loopback interface, and therefore, the BGP route needs to perform recursion. Specifically, the system searches the IP routing table for a direct route (IGP route in most cases) that is destined for the next hop IP address of the BGP route and then adds the next hop IP address and outbound interface of the IGP route to the IP routing table to generate a FIB entry.

The next hop IP address of a BGP VPN route is the IP address of a non-directly connected PE's loopback interface, and the BGP route needs to recurse to a tunnel. Specifically, the system searches the tunnel list for a tunnel that is destined for this loopback IP address and then adds the tunnel information to the routing table to generate a FIB entry.

Static and Dynamic Routes

Static routes can be easily configured and have low requirements on the system. They apply to simple, stable, and small-scale networks. However, they cannot automatically adapt to network topology changes. Therefore, static routes require subsequent maintenance.

Dynamic routing protocols have their routing algorithms and can automatically adapt to network topology changes. They apply to the network equipped with a number of Layer 3 devices. Dynamic route configurations are complex. Dynamic routes have higher requirements on a system than static ones do and consume network resources.

Classification of Dynamic Routing Protocols

Dynamic routing protocols can be classified according to the following dimensions:

Based on the Application Scope

Based on the application scope, routing protocols are classified into the following types:

- Interior Gateway Protocols (IGPs): run within an AS. Common IGPs include RIP, OSPF, and IS-IS.
- Exterior Gateway Protocols (EGPs): run between ASs. At present, BGP is the most widely used EGP.

Based on the Routing Algorithm

Based on the algorithm used, routing protocols can be classified into the following types:

- Distance-vector routing protocols: include RIP and BGP. BGP is also called a path-vector protocol.
- Link-state routing protocols: include OSPF and IS-IS.

The main difference between the preceding two algorithms lies in the methods of discovering and calculating routes.

Based on the Destination Address Type

Based on the destination address type, routing protocols are classified into the following types:

- Unicast routing protocols: include RIP, OSPF, BGP, and IS-IS.
- Multicast routing protocols: include Protocol Independent Multicast-Sparse Mode (PIM-SM).

This chapter describes unicast routing protocols. For details about multicast routing protocols, see *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Feature Description - IP Multicast*.

Static routes and dynamic routes discovered by routing protocols are managed in a unified manner. These routes can be imported from each other to implement **Re-advertisement of Routing Information**.

Routing Protocol and Route Priority

Route Priority

Routing protocols (including static route) may discover different routes to the same destination, but not all the routes are optimal. Only one routing protocol is used each time to determine the optimal route to a destination. Routing protocols and static routes have their priorities. When multiple route sources exist, the route with the highest priority (smallest value) is selected as the optimal route. [Table 1-1](#) lists routing protocols and their default priorities.

Value 0 indicates a direct route, and value 255 indicates any route learned from an unreliable source. A smaller value indicates a higher priority.

Table 1-1 Routing protocols and their default priorities

Routing Protocol or Route Type	Routing Priority
Direct	0
OSPF	10
IS-IS	15
Static	60
RIP	100
OSPF ASE	150
OSPF NSSA	150
BGP	255
IBGP	255
EBGP	255

Priorities can be manually configured for routes of routing protocols, except for direct routes. In addition, the priorities of static routes can be different.

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X defines external and internal priorities. The external priorities refer to the priorities set by users for routing protocols. [Table 1-1](#) lists the default external priorities.

When different routing protocols are configured with the same priority, the system selects the optimal route based on the internal priority. For the internal priority of each routing protocol, see [Table 1-2](#).

Table 1-2 Internal priority of routing protocols

Routing Protocol or Route Type	Routing Priority
Direct	0
OSPF inter-area	10
OSPFv3 inter-area	10
IS-IS Level-1	15
IS-IS Level-2	18
EBGP	20
Static	60
UNR	65
RIP	100
RIPng	100
OSPF ASE	150
OSPFv3 ASE	150
OSPF NSSA	150
OSPFv3 NSSA	150
IBGP	200

For example, both an OSPF route and a static route are destined for 10.1.1.0/24, and their protocol priorities are set to 5. In this case, the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X selects the optimal route based on the internal priorities listed in **Table 1-2**. The internal priority of OSPF (10) is higher than that of the static route (60). Therefore, the device selects the route discovered by OSPF as the optimal route.

 **NOTE**

- If multiple OSPFv2 processes learn routes to the same destination and the external and internal priorities of the routes are the same, the system selects the route with the smallest link cost; if the link costs of the routes are the same, the routes participate in load balancing. If multiple OSPFv3 processes learn routes to the same destination and the external and internal priorities of the routes are the same, the system selects the route with the smallest process ID.
- If multiple IS-IS processes learn routes to the same destination and the external and internal priorities of the routes are the same, the device selects the route with the smallest link cost; if the link costs of the routes are the same, the routes perform load balancing.
- If multiple RIP/RIPng processes learn routes to the same destination and the external and internal priorities of the routes are the same, the device selects the route with the smallest link cost; if the link costs of the routes are the same, the routes perform load balancing.

Priority-based Route Convergence

Definition

Priority-based route convergence is an important technology to improve network reliability. It provides faster route convergence for key services. For example, when a fault occurs on the network, to shorten the interruption of key services, real-time multicast services require fast convergence of routes to the multicast source. The MPLS VPN transport network requires fast convergence of end-to-end routes between PEs.

Different routes can be set with different convergence priorities, which can be critical, high, medium, and low listed in descending order. Critical is the highest convergence priority; low is the lowest convergence priority. The system performs route convergence based on the convergence priorities and certain convergence rules. That is, route convergence is performed based on a certain scheduling ratio to guide uninterrupted service forwarding.

Purpose

With the network convergence, requirements on service differentiation increase. Carriers require that routes for key services, such as voice over IP (VoIP) and video conferencing services, converge faster than those for common services. Therefore, the system needs to process different routes based on different convergence priorities to improve network reliability.

Route Convergence Priority

Priorities in route convergence are critical, high, medium, and low, which are listed in descending order. [Table 1-3](#) lists the default convergence priorities of public network routes. You can set convergence priorities for routes as needed based on the specific networking.

Table 1-3 Default convergence priorities of public network routes

Routing Protocol or Route Type	Convergence Priority
Direct	critical
Static	medium
OSPF and IS-IS host routes with 32-bit masks	medium
OSPF (except host routes with 32-bit masks)	low
IS-IS (except host routes with 32-bit masks)	low
RIP	low
BGP	low

 NOTE

For VPN routes, the convergence priorities of only the OSPF and IS-IS host routes with 32-bit masks are medium, and those of the other routes are low.

Typical Application

IGPs run on the network shown in [Figure 1-3](#), the receiver is connected to Device A, and the multicast source server 10.10.10.10/32 is connected to Device B. It is required that the route to the multicast server converge prior to other routes such as 10.12.10.0/24. In this case, you can set the convergence priority of the route 10.10.10.10/32 to be higher than that of the route 10.12.10.0/24. In this manner, when routes converge on the network, the route 10.10.10.10/32 to the multicast source converges first, ensuring the forwarding of multicast services.

Figure 1-3 Network diagram of priority-based route convergence

Load Balancing and Route Backup

Load Balancing

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports the multi-route model (multiple routes with the same destination and priority). Load balancing can be performed among multiple routes discovered by the same routing protocol if they have the same destination and cost. In each routing protocol view, you can run the **maximum load-balancing number** command to perform load balancing. Load balancing is classified into the following types:

- Per-packet load balancing

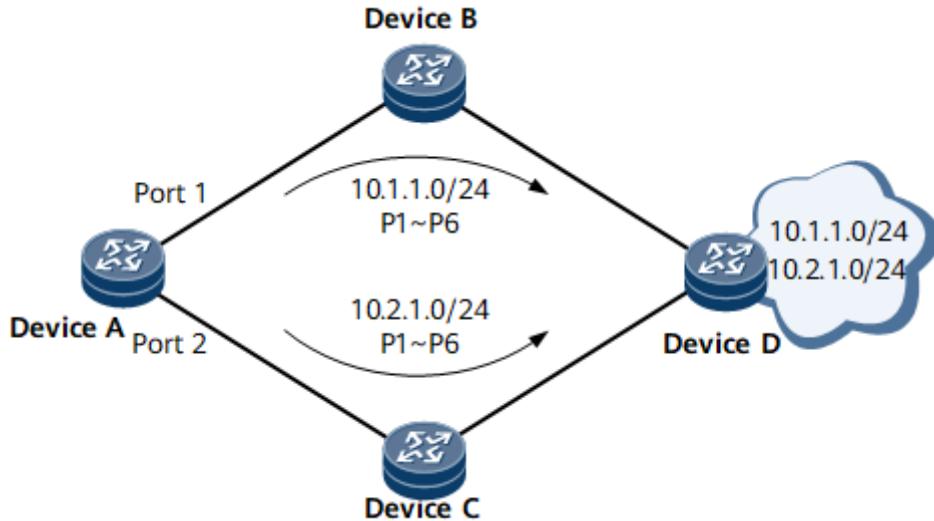

When per-packet load balancing is configured, the router forwards packets destined for the same destination through each path at the IP layer, and each time the next hop address is different from the one selected last time.

- Per-flow load balancing

When per-flow load balancing is configured, the router forwards packets according to the 5-tuple (source IP address, destination IP address, source port number, destination port number, and protocol). If packets have the same 5-

tuple, the router always selects the next hop address that is the same as the one selected last time to send the packets. [Figure 1-4](#) shows the networking.

Figure 1-4 Networking diagram of per-flow load balancing

Device A needs to forward packets to 10.1.1.0/24 and 10.2.1.0/24. In per-flow load balancing, packets of the same flow are always transmitted along the previous path. Device A forwards packets as follows:

- The first packet P1 to 10.1.1.0/24 is forwarded through Port 1, and all subsequent packets to 10.1.1.0/24 are forwarded through Port 1.
- The first packet P1 to 10.2.1.0/24 is forwarded through Port 2, and all subsequent packets to 10.2.1.0/24 are forwarded through Port 2.

Currently, RIP, OSPF, BGP, and IS-IS support load balancing, and static routes also support load balancing.

NOTE

The maximum number of equal-cost routes for load balancing varies with the router model.

Route Backup

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports route backup to improve network reliability. You can configure multiple routes to the same destination as required. The route with the highest priority functions as the primary route, and the other routes with lower priorities function as backup routes.

In most cases, the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X uses the primary route to forward packets. If the link of the primary route fails, the primary route becomes inactive. The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X then selects a backup route with the highest priority to forward packets, and the original primary route becomes a backup route. When the original primary route recovers, the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X restores and reselects the optimal route. Because the original

primary route has the highest priority, the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X selects this route to send packets. Therefore, the backup route becomes the primary route.

Principles of IP FRR

Overview

Fast Reroute (FRR) functions when the lower layer (physical layer or data link layer) detects a fault. The lower layer reports the fault to the upper layer routing system and immediately forwards packets through a backup link.

If a link fails, FRR helps reduce the impact of the link failure on services transmitted on the link.

Background

On traditional IP networks, when a fault occurs at the lower layer of the forwarding link, the physical interface on the router goes Down. After the router detects the fault, it instructs the upper layer routing system to recalculate routes and then update routing information. The routing system takes several seconds to reselect an available route.

For services that are sensitive to packet loss and delay, a convergence time of several seconds is intolerable because it may lead to service interruptions. For example, the maximum convergence time tolerable for Voice over IP (VoIP) services is within milliseconds. IP FRR enables the forwarding system to detect a fault and then to take measures to restore services as soon as possible.

Classification and Implementation

IP FRR, which is designed for routes on IP networks, consists of public network IP FRR and VPN IP FRR.

- Public network IP FRR: protects routers on the public network.
- VPN IP FRR: protects Customer Edges (CEs).

The static routes that are imported between public and private networks do not support IP FRR.

IP FRR is implemented as follows:

- IP FRR can be enabled or disabled using commands.
- When optimal routes are selected from the routes discovered by routing protocols, a backup link is selected for each preferred primary link based on the protocol priority, and then the forwarding information of primary and backup links is provided for the forwarding engine.

Implementation of IP FRR Between Different Protocols

When IP FRR between different protocols is enabled, and optimal routes are selected from protocol routes, a backup link is selected for each preferred primary link based on the protocol priority, and then the forwarding information of primary and backup links is provided for the forwarding engine.

If the forwarding engine detects that the primary link is unavailable after IP FRR between different protocols is enabled, the system can use the backup link to forward traffic before the routes converge on the control plane.

Comparison Between IP FRR and Load Balancing

Table 1-4 Comparison between IP FRR and load balancing

Feature	Description
IP FRR	Implements FRR through a backup route. IP FRR is applicable to networks where a master link and a backup link exist and load balancing is not configured.
Load balancing	Implements fast route switching through equal-cost routes and applies to the multi-link networking with load balancing.

Re-advertisement of Routing Information

Different routing protocols may discover different routes because they adopt different routing algorithms. When the scale of a network is large and multiple routing protocols run on the network, these protocols need to re-advertise their discovered routes.

On the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X, the routes discovered by a routing protocol can be imported into the routing table of another routing protocol. Each protocol has its mechanism to import routes. For details, see "Routing Policy."

Indirect Next Hop

Definition

Indirect next hop is a technique used to speed up route convergence. This technique can change the direct association between route prefixes and next hop information into an indirect association. Indirect next hop allows next hop information to be refreshed independently of the prefixes of the same next hop, which speeds up route convergence.

Purpose

In the scenario requiring route recursion, when IGP routes or tunnels are switched, forwarding entries are rapidly refreshed, which implements fast route convergence and reduces the impact of route or tunnel switching on services.

Mapping Between the Route Prefix and the Next Hop

Mapping between route prefixes and next hops is the basis of indirect next hop. To meet the requirements of route recursion and tunnel recursion in different scenarios, next hop information includes the address family, original next hop address, and tunnel policy. The system assigns an index to each next hop,

performs route recursion, communicates the recursion result to the routing protocol, and then delivers forwarding entries.

On-Demand Route Recursion

On the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X, the route to a reachable address is called a dependent route. The system forwards packets based on dependent routes. The process of finding a dependent route based on the next hop address is called route recursion.

On-demand route recursion indicates that when a dependent route changes, only the next hop associated with the dependent route performs recursion again. If the route destination address is the original next hop address or network segment address of next hop information, any route changes affect the recursion result of the next hop information. Otherwise, route changes do not affect next hop information. Therefore, when a route changes, you can perform recursion again only on the associated next hop by assessing the destination address of the route. For example, if the original next hop address of the route 2.2.2.2/32 is 1.1.1.1, the route that the original next hop 1.1.1.1 depends on may be 1.1.1.1/32 or 1.1.0.0/16. If the route 1.1.1.1/32 or 1.1.0.0/16 changes, the recursion result of the original next hop 1.1.1.1 is affected.

With respect to tunnel recursion, when a tunnel alternates between Up and Down, perform recursion again on the next hop whose original next hop address is the same as the destination address of the tunnel.

Recursion Policy

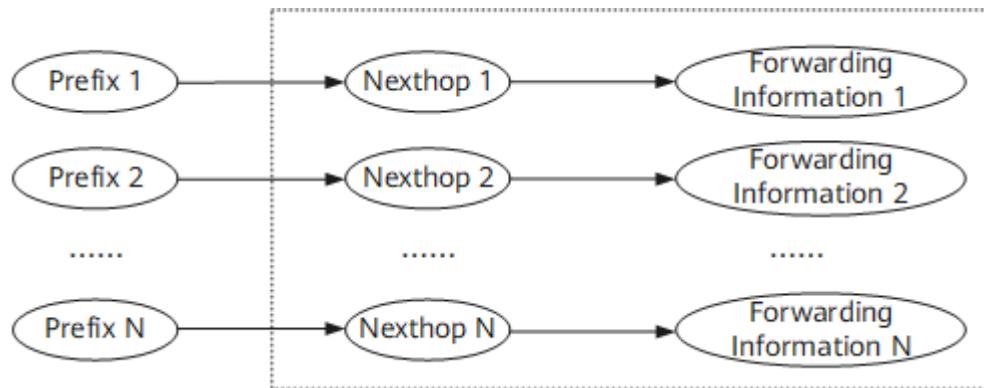

A recursion policy is used to control the recursion result of the next hop to meet requirements of different scenarios. In route recursion, behaviors do not need to be controlled by the recursion policy. Instead, recursion behaviors only need to comply with the longest match rule. In addition, the recursion policy needs to be applied only when VPN routes recurse to tunnels.

By default, the system selects Label Switched Paths (LSPs) for VPNs without performing load balancing. If load balancing or other types of tunnels are required, configure a tunnel policy and bind it to a tunnel. After the tunnel policy is applied, the system uses the tunnel bound to the tunnel policy or selects a tunnel based on the priorities specified in the tunnel policy during next hop recursion.

Mechanism for Indirect Next Hop

Without indirect next hop, the forwarding information corresponds to the prefix, and therefore, the route convergence time is decided by the number of route prefixes. With indirect next hop, multiple route prefixes correspond to one next hop. Forwarding information is added to the forwarding table using the next hop, and traffic with relevant route prefixes can be switched, which speeds up route convergence.

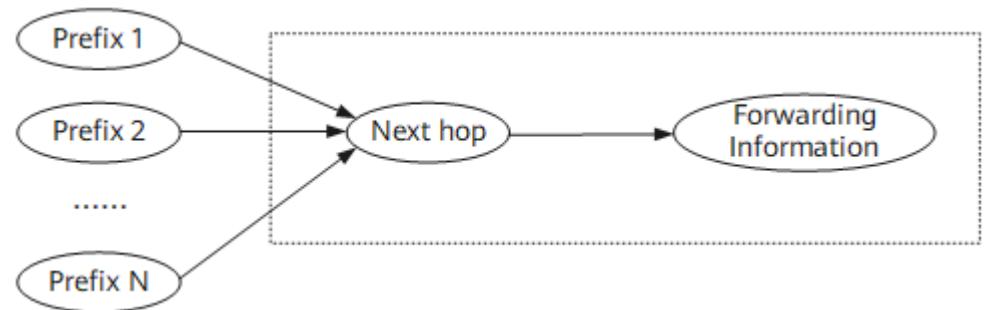

Figure 1-5 Implementation without indirect next hop

As shown in **Figure 1-5**, without indirect next hop, prefixes are totally independent, each corresponding to its next hop and forwarding information. When a dependent route changes, the next hop corresponding to each prefix performs recursion and forwarding information is updated based on the prefix. In this case, the convergence time is decided by the number of prefixes.

Note that prefixes of a BGP peer have the same next hop, forwarding information, and refreshed forwarding information.

Figure 1-6 Implementation with indirect next hop

As shown in **Figure 1-6**, with indirect next hop, prefixes of routes from the same BGP peer share the same next hop. When a dependent route changes, only the shared next hop performs recursion and forwarding information is updated based on the next hop. In this case, routes of all prefixes can converge at a time. Therefore, the convergence time is irrelevant to the number of prefixes.

Comparison Between Route Recursion and Tunnel Recursion

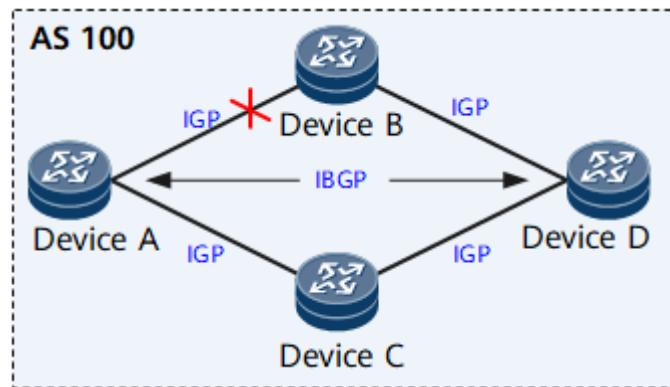

The following table lists differences between route recursion and tunnel recursion.

Table 1-5 Differences between route recursion and tunnel recursion

Recursion Type	Description
Route recursion	<ul style="list-style-type: none"> Applies to BGP public network routes. Is triggered by route changes. Supports next hop recursion based on the specified routing policy.
Tunnel recursion	<ul style="list-style-type: none"> Applies to BGP VPN routes. Is triggered by tunnel or tunnel policy changes. Recursion behaviors can be controlled using a tunnel policy to meet requirements of different scenarios.

IBGP Route Recursion to an IGP Route

Figure 1-7 Networking for IBGP route recursion

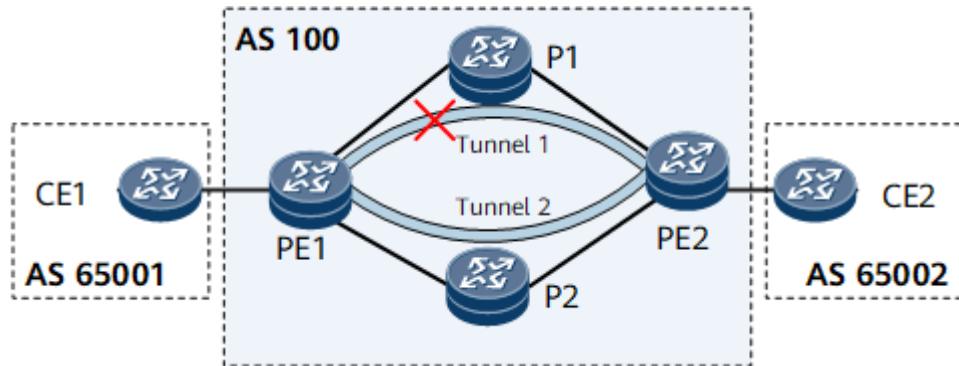

In [Figure 1-7](#), an IBGP peer relationship is established between Device A and Device D. The IBGP peer relationship is established between two loopback interfaces on the routers, but the next hop cannot be used to guide packet forwarding, because it is not directly reachable. Therefore, to refresh the forwarding table and guide packet forwarding, the system needs to search for the actual outbound interface and directly connected next hop based on the original IBGP next hop.

Device D receives 100,000 routes from Device A. These routes have the same original BGP next hop. After recursion, these routes eventually follow the same IGP path (A->B->D). If the IGP path (A->B->D) fails, these IBGP routes do not need to perform recursion separately, and the relevant forwarding entries do not need to be refreshed one by one. Note that only the shared next hop needs to perform recursion and be refreshed. Consequently, these IBGP routes converge to the path (A->C->D) on the forwarding plane. Therefore, the convergence time depends on only the number of next hops, not the number of prefixes.

If Device A and Device D establish a multi-hop EBGP peer relationship, the convergence procedure is the same as the preceding one. Indirect next hop also applies to the recursion of a multi-hop EBGP route.

VPN Routes Recursion to a Tunnel

Figure 1-8 Networking for VPN route recursion

In [Figure 1-8](#), a neighbor relationship is established between PE1 and PE2, and PE2 receives 100,000 VPN routes from PE1. These routes have the same original BGP next hop. After recursion, these VPN routes eventually follow the same public network tunnel (tunnel 1). If tunnel 1 fails, these routes do not need to perform recursion separately, and the relevant forwarding entries do not need to be refreshed one by one. Note that only the shared next hop needs to perform recursion, and the relevant forwarding entries need to be refreshed. Consequently, these VPN routes converge to tunnel 2 on the forwarding plane. In this manner, the convergence time depends on only the number of next hops, not the number of prefixes.

Default Route

Default routes are special routes. In most cases, they are configured by administrators. Default routes can also be generated by dynamic routing protocols, such as OSPF and IS-IS.

Default routes are used only when no matching routing entry is available for packet forwarding in the routing table. A default route in the routing table is the route to the network 0.0.0.0 (with mask 0.0.0.0). You can check whether the default route is configured using the **display ip routing-table** command.

If the destination address of a packet does not match any entry in the routing table, the packet is sent along a default route. If no default route exists and the destination address of the packet does not match any entry in the routing table, the packet is discarded. An Internet Control Message Protocol (ICMP) packet is then sent, informing the originating host that the destination host or network is unreachable.

Multi-Topology

Multi-Topology Overview

On a traditional IP network, only one unicast topology exists, and only one unicast forwarding table is available on the forwarding plane, which forces services transmitted from one router to the same destination address to share the same

next hop, and various end-to-end services, such as voice and data services, to share the same physical links. As a result, some links may become heavily congested whereas others remain relatively idle. To address this problem, configure multi-topology to divide a physical network into different logical topologies for different services.

By default, the base topology is created on the public network. The class-specific topology can be added or deleted in the public network address family view. Each topology contains its own routing table. The class-specific topology supports the addition, deletion, and import of protocol routes.

The base topology cannot be deleted.

Direct Routes Supporting Multi-Topology

Direct routes can be added to or deleted from the routing table of any topology. The same routes can also be added to multiple topologies, independent of each other.

Direct routes associated with interfaces are added to the base topology by default. Direct routes in the base topology are not deleted, and the base topology contains all direct routes.

Static Routes Supporting Multi-Topology

Static routes can be added to or deleted from the routing table of any topology. The routes with the same prefix, outbound interface, and next hop can also be added to multiple topologies, independent of each other.

Static routes, by default, are configured in the base topology. However, they can be configured in a specified class-specific topology and can be changed or deleted.

Static routes have no outbound interfaces, and therefore, need to perform recursion based on the next hop. In this case, you cannot specify the topology in which the next hop resides.

Public network static route recursion to a VPN next hop or VPN static route recursion to a public network next hop can be configured only in the base topology. When configuring static routes, you cannot specify the name of the topology in which the destination resides.

Association Between Direct Routes and a VRRP Group

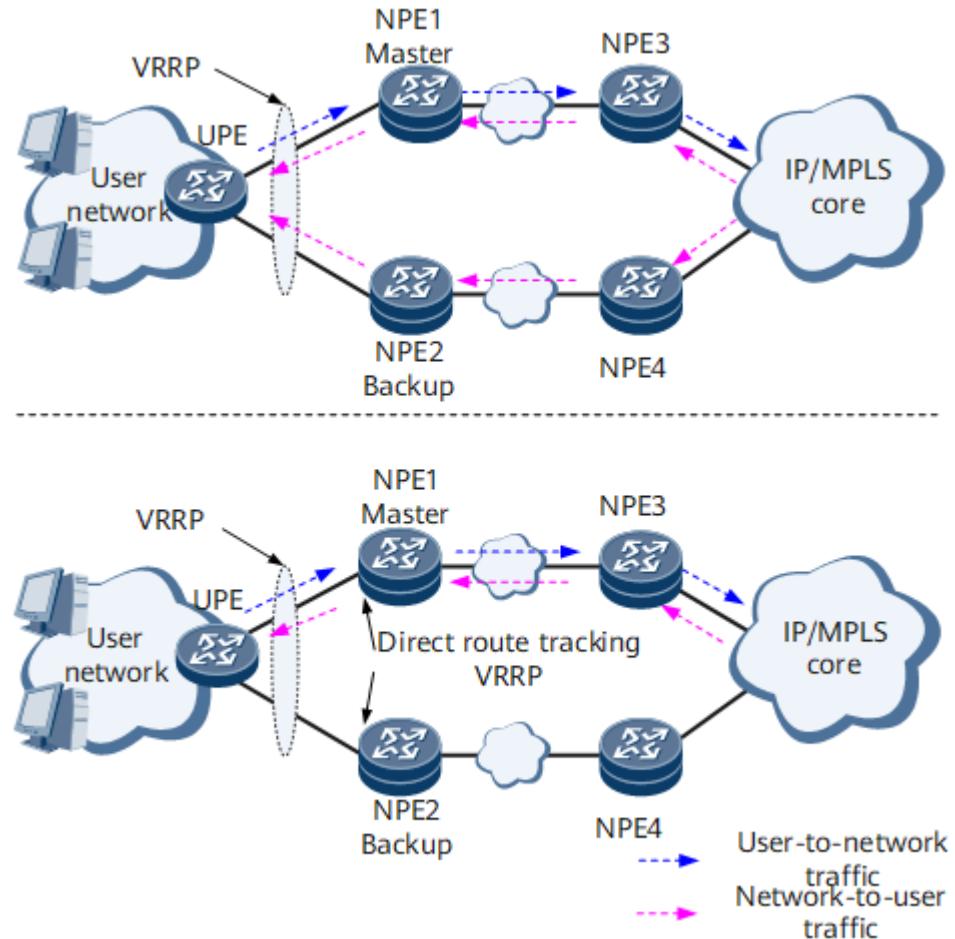

Background

A VRRP group is configured on Device1 and Device2 on the network shown in [Figure 1-9](#). Device1 is a master device, whereas Device2 is a backup device. The VRRP group serves as a gateway for users. User-to-network traffic travels through Device1. However, network-to-user traffic may travel through Device1, Device2, or both of them over a path determined by a dynamic routing protocol. Therefore, user-to-network traffic and network-to-user traffic may travel along different paths, which interrupts services if firewalls are attached to devices in the VRRP group, complicates traffic monitoring or statistics collection, and increases costs.

To address the preceding problems, the routing protocol is expected to select a route passing through the master device so that the user-to-network and network-

to-user traffic travels along the same path. Association between direct routes and a VRRP group can meet expectations by allowing the dynamic routing protocol to select a route based on the VRRP status.

Figure 1-9 Association between direct routes and a VRRP group

Related Concepts

VRRP is a widely used fault-tolerant protocol that groups multiple routing devices into a VRRP group, improving network reliability. A VRRP group consists of a master device and one or more backup devices. If the master device fails, the VRRP group switches services to a backup device to ensure communication continuity and reliability.

A device in a VRRP group operates in one of three states:

- **Master:** If a network is working correctly, the master device transmits all services.
- **Backup:** If the master device fails, the VRRP group selects a backup device as the new master device to take over traffic and ensure uninterrupted service transmissions.
- **Initialize:** A device in the Initialize state is waiting for an interface Startup message to switch its status to Master or Backup.

 NOTE

For details about VRRP, see *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Feature Description - Network Reliability - VRRP*.

Implementation

Association between direct routes and a VRRP group allows VRRP interfaces to adjust the costs of direct network segment routes based on the VRRP status. The direct route with the master device as the next hop has the lowest cost. A dynamic routing protocol imports the direct routes and selects the direct route with the lowest cost. For example, VRRP interfaces on Device1 and Device2 on the network shown in [Figure 1-9](#) are configured with association between direct routes and the VRRP group. The implementation is as follows:

- Device1 in the Master state sets the cost of its route to the directly connected virtual IP network segment to 0 (default value).
- Device2 in the Backup state increases the cost of its route to the directly connected virtual IP network segment.

A dynamic routing protocol selects the route with Device1 as the next hop because this route costs less than the other route. Therefore, both user-to-network traffic and network-to-user traffic travel through Device1.

Usage Scenario

When a data center is used, firewalls are attached to devices in a VRRP group to improve network security. Network-to-user traffic cannot pass through a firewall if it travels over a path different than the one used by user-to-network traffic.

When an IP radio access network (RAN) is configured, VRRP is configured to set the master/backup status of aggregation site gateways (ASGs) and radio service gateways (RSGs). Network-to-user and user-to-network traffic may pass through different paths, complicating network operation and management.

Association between direct routes and a VRRP group can address the preceding problems by ensuring the user-to-network and network-to-user traffic travels along the same path.

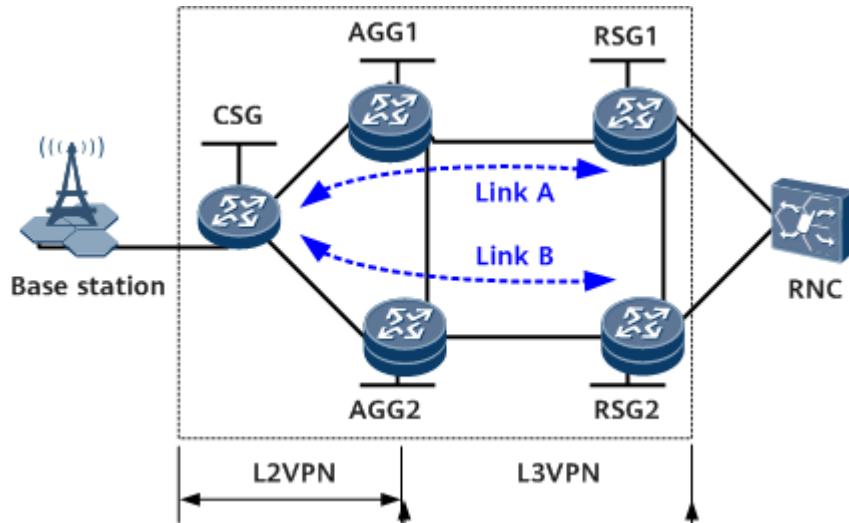

Direct Routes Responding to VE Interface Status Changes After a Delay

Background

On the network shown in [Figure 1-10](#), an L2VPN connection is set up between each AGG and the CSG, and BGP VPNv4 peer relationships are set up between the AGGs and RSGs. Layer 3 Virtual Ethernet (L3VE) interfaces are configured on AGGs and VPN instances are bound to the L3VE interfaces, so that the CSG can access the Layer 3 Virtual Private Network (L3VPN). The AGGs are configured to import direct routes into BGP and advertise these direct routes to their VPNv4 peers (RSGs). If AGG1 restarts or the CSG-AGG1 link fails, traffic switches over to Link B. After AGG1 or the CSG-AGG1 link recovers, the VE interface on AGG1 goes from down to up, and AGG1 immediately generates a direct route and advertises the route to the RSGs. The downstream traffic then switches back to Link A. However, AGG1 has not learned the MAC address of the base station yet. As a result, downstream traffic is lost.

To prevent this problem, configure RSGs not to preferentially select the routes advertised by AGG1 until AGG1 learns the MAC address of the base station. In this case, you can configure a delay for direct routes to respond to VE interface status changes.

Figure 1-10 Networking for direct routes responding to VE interface status changes after a delay

Implementation

After a delay is configured for direct routes to respond to VE interface status changes after a delay, the cost of the direct route is modified to the configured cost (greater than the default value 0) when the VE interface on AGG1 goes from down to up. After the configured delay expires, the cost of the direct route restores to the default value 0. Because BGP has imported the direct route and has advertised it to RSGs, the cost value determines whether RSGs preferentially select the direct route.

RSGs preferentially transmit traffic over Link B before AGG1 learns the MAC address of the base station, which prevents traffic loss.

Usage Scenario

Direct routes responding to VE interface status changes after a delay applies to IP radio access networks (RANs) on which an L2VPN accesses an L3VPN.

Association Between the Direct Route and PW Status

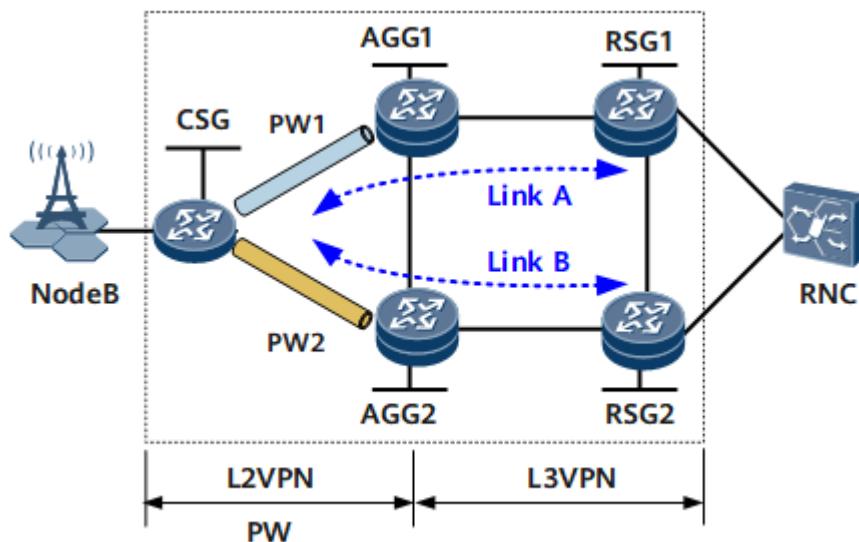

Background

In [Figure 1-11](#), PWs are set up between the AGGs and the CSG. BGP virtual private network version 4 (VPNv4) peer relationships are set up between the AGGs and RSGs. Layer 3 virtual Ethernet (L3VE) interfaces are configured on the AGGs, and VPN instances are bound to the L3VE interfaces so that the CSG can access the L3VPN. BGP is configured on the AGGs to import direct routes between the CSG and AGGs. The AGGs convert these direct routes to BGP VPNv4 routes before advertising them to the RSGs.

AGG1 functions as the master device in [Figure 1-11](#). In most cases, the RSGs select routes advertised by AGG1, and traffic travels along Link A. If AGG1 or the CSG-AGG1 link fails, traffic switches over to Link B. After AGG1 or the CSG-AGG1 link recovers, the L3VE interface on AGG1 goes from Down to Up, and AGG1 immediately generates a direct route destined for the CSG and advertises the route to the RSGs. Downstream traffic then switches over to Link A. However, PW1 is on standby. As a result, downstream traffic is lost.

To address this problem, associate the direct route and PW status. After the association is configured, the RSG preferentially selects the direct route only after PW1 becomes active.

Figure 1-11 Networking for the association between the direct route and PW status

Implementation

Configuring the association between the direct route and PW status allows a VE interface to adjust the cost value of the direct route based on PW status. The cost value determines whether the RSGs preferentially select the direct route because BGP has imported the direct route and has advertised it to RSGs. For example, if you associate the direct route and PW status on the network shown in [Figure 1-11](#), the implementation is as follows:

- When PW1 becomes active, the cost value of the direct route between the CSG and AGG1 restores to the default value 0. RSGs preferentially transmit traffic over Link A.
- When PW1 is on standby, the cost value of the direct route between the CSG and AGG1 is modified to a configured value (greater than 0). RSGs preferentially transmit traffic over Link B, which reduces traffic loss.

Usage Scenario

This feature applies to IP radio access networks (RANs) on which primary/secondary PWs are configured between the CSG and AGGs.

Vlink Direct Route Advertisement

Background

By default, ARP or IPv6 NDP Vlink direct routes are used only for data forwarding in the same VLAN. To control the routing table size and maintain routing table stability, these direct routes cannot be imported to dynamic routing protocols for advertisement. In some cases, the device needs to perform operations based on specific routes of VLAN users. For example, a device needs to apply a unique export policy for each VLAN user to divert traffic from a remote device. In this case, ARP or IPv6 NDP Vlink routes need to be imported to a dynamic routing protocol and advertised to the remote device.

Related Concepts

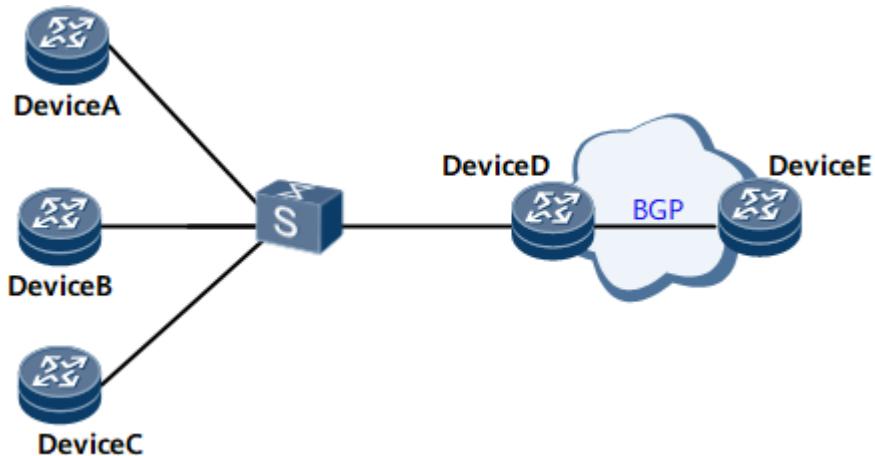

ARP Vlink direct routes: routes with VLAN users' physical interfaces that are learned using ARP. Such routes are used to forward IP packets in VLAN networking because packets cannot be forwarded through some logical interfaces. After the VLANIF interface, QinQ interface, or dot1q VLAN tag termination sub-interface learns an ARP entry of a remote end, an ARP Vlink direct route with a 32-bit mask is generated and displayed in the routing table. A common physical interface does not generate an ARP Vlink direct route with a 32-bit mask.

NDP Vlink direct routes: routing entries carrying IPv6 addresses of VLAN users' physical interfaces. These IPv6 addresses are learned and resolved using NDP.

Implementation

On the network shown in [Figure 1-12](#), three users (Device A, Device B, and Device C) are connected to the logical interface of Device D. Device E needs to communicate with Device B, not with Device A or Device C. In this scenario, Vlink direct route advertisement can be enabled on Device D. Then Device D obtains each physical interface of the three users and uses a route-policy to filter out network segment routes and the routes destined for Device A and Device C.

Figure 1-12 Networking for Vlink direct route advertisement

Usage Scenario

Vlink direct route advertisement is applicable to networks in which a device needs to add Vlink direct routes with physical interfaces of VLAN users to the routing table of a dynamic routing protocol before advertising the routes to remote ends.

Benefits

With Vlink direct route advertisement, a device can import Vlink direct routes into the routing table of a dynamic routing protocol (such as an IGP or BGP) and then use different export policies during route advertisement to implement precise route control.

Association Between the IPv4 Direct Routes and IPsec Instance Status

[Figure 1-13](#) shows an IP radio access network (IPRAN) scenario, and some services require high security. To meet such requirements, cell site gateways (CSGs) encrypt data of these services using IPsec. After the data flows to RSGs (IPsec gateways) through an IPsec tunnel, the RSGs decrypt the data. In most cases, carriers deploy master and backup RSGs and configure the same IP address for the IPsec tunnel interfaces of the master and backup RSGs to improve network reliability.

Without the association between IPv4 direct routes and IPsec instance status, IPv4 direct routes with the same prefix generated on the IPsec tunnel interfaces of the master and backup RSGs share the same default cost (0). As a result, after receiving these routes from the master and backup RSGs, CSGs cannot select an optimal one based on the cost.

Association between IPv4 direct routes and IPsec instance status can address this problem. After the association is configured:

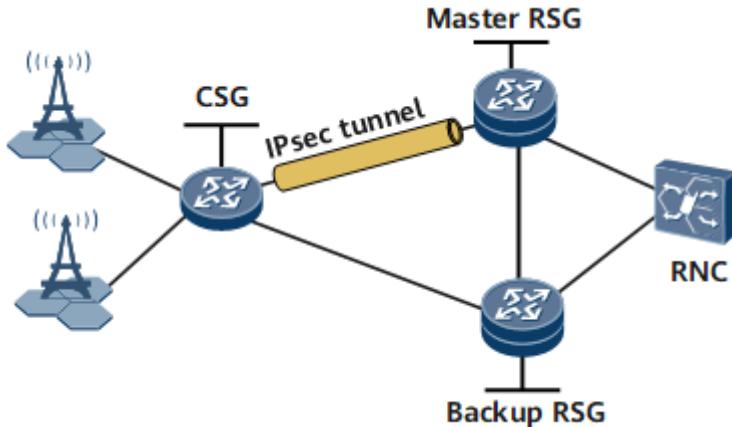

- If the IPsec instance status is master on an IPsec tunnel interface, the cost of the IPv4 direct routes generated on the interface is 0.
- If the IPsec instance status is backup on an IPsec tunnel interface or the system cannot detect the IPsec instance status, the cost of the IPv4 direct routes generated on the interface is the cost configured on the interface.

NOTE

In IPsec dual-device hot backup scenarios, if a tunnel interface borrows the IP address of another interface, the cost of direct routes on the tunnel interface cannot be associated with the IPsec instance status.

After receiving the IPv4 direct routes with the same prefix from the master and backup RSGs, CSGs can select an optimal one based on the cost. Therefore, the CSGs can transmit data encrypted using IPsec to the correct RSG.

Figure 1-13 Networking for the association between IPv4 direct routes and IPsec instance status

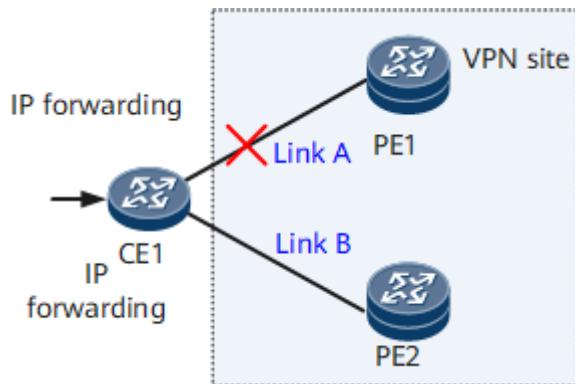

1.1.1.1.3 Application Scenarios for IP Routing

Typical Application of IP FRR

In **Figure 1-14**, CE1 is dual-homed to PE1 and PE2. CE1 is configured with two outbound interfaces and two next hops. Link B functions as the backup of link A. If link A fails, traffic can be rapidly switched to link B.

Figure 1-14 Configuring IP FRR

Data Center Applications of Association Between Direct Routes and a VRRP Group

Service Overview

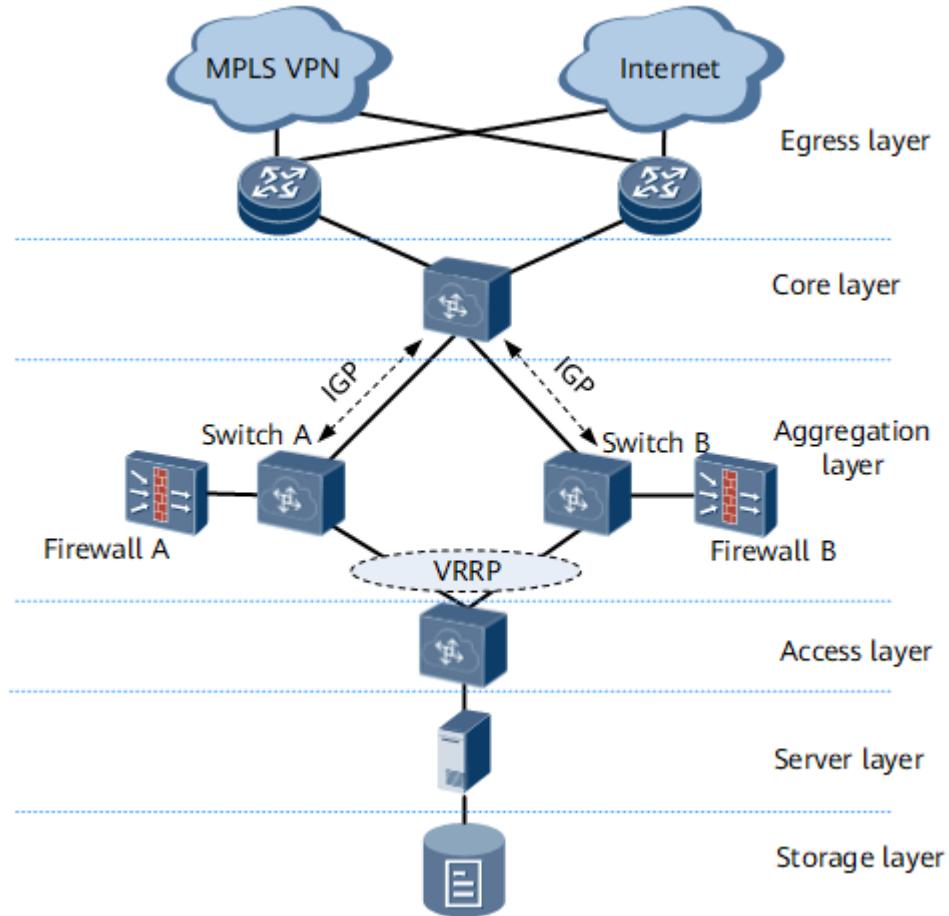

A data center, used for service access and transmission, consists of many servers, disk arrays, security devices, and network devices that store and process a great number of services and applications. Firewalls are used to improve data security, and VRRP groups are configured to improve communication reliability. VRRP may cause user-to-network traffic and network-to-user traffic to travel along different paths, and as a result, the firewall may discard the network-to-user traffic because

of path inconsistency. To address this problem, association between direct routes and a VRRP group must be configured.

Networking Description

Figure 1-15 shows a data center network. A server functions as a core service module in the data center. A VRRP group protects data exchanged between the server and core devices, improving service security. Firewalls are attached to devices in the VRRP group to improve network security.

Figure 1-15 Data center network

Feature Deployment

The master device transmits server traffic to a core device. When the core device attempts to send traffic to the server, the traffic can only pass through a firewall attached to the master device. On the network shown in **Figure 1-15**, the server sends data destined for the core device through the master device, and the core device sends data destined for the server along a path that an Interior Gateway Protocol (IGP) selects. The association between the direct routes and a VRRP group can be configured on switch A and switch B so that the IGP selects a route based on VRRP status. The IGP forwards core-device-to-server traffic over the same path as the one over which server-to-core-device traffic is transmitted, which prevents the firewall from discarding traffic.

Application of Association Between Direct Routes and a VRRP Group on an IP RAN

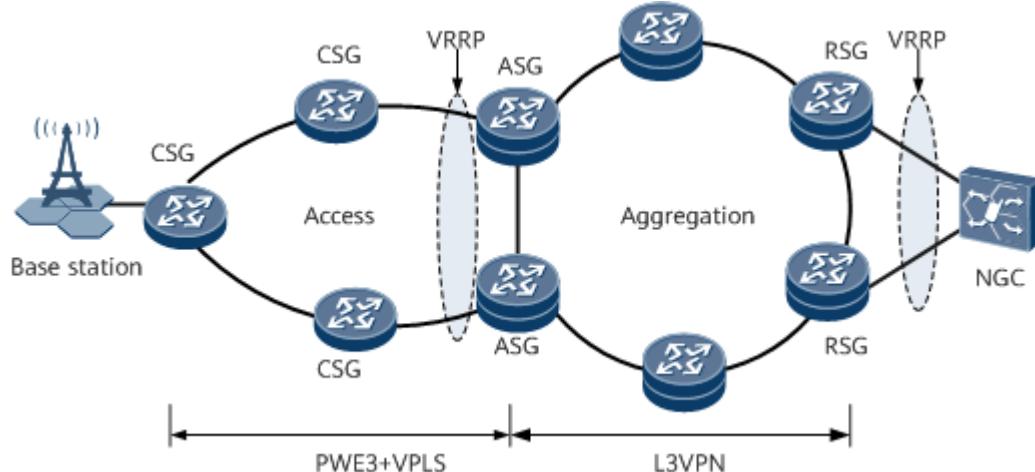

Service Overview

In an IP RAN scenario, base stations and NGCs do not support dynamic routing configuration. Therefore, you need to configure static routes with the addresses of ASGs and RSGs specified for communication with the aggregation network. VRRP is configured to provide ASG and RSG redundancy, improving device reliability and ensuring non-stop transmission of services, such as voice, video, and cloud application services over mobile transport networks.

Networking Description

Figure 1 shows VRRP-based gateway protection applications on an IP RAN. A base station is dual-homed to VRRP-enabled ASGs to communicate with the aggregation network. The traffic from the base station to the NGC passes through the master ASG in the VRRP group, whereas the traffic from the NGC to the base station is transmitted over a path selected by a dynamic routing protocol after leaving the aggregation network. Similarly, the RSGs connecting the NGC and the aggregation network also use VRRP to implement redundancy. The upstream and downstream traffic paths on the NGC side also have the same problem.

Figure 1-16 VRRP application in the IP RAN gateway protection solution

Feature Deployment

According to the networking description, the upstream and downstream traffic paths on both sides of the aggregation network may be inconsistent. Path inconsistency causes operation and management difficulties. For example, upstream traffic enters the aggregation network through the master ASG, whereas downstream traffic flows out of the aggregation network through the backup ASG. Path inconsistency complicates traffic monitoring or statistics collection and increases the cost. In addition, the VRRP technology is used to implement device-level redundancy backup. When the master device is running properly, the backup device does not carry any traffic. Therefore, the fact that the backup ASG carries downstream traffic does not comply with the original intention of the redundancy backup design. Association between direct routes and a VRRP group can be configured to ensure path consistency.

On the base station side, you can associate direct routes with a VRRP group on ASG interfaces configured with service VRRP, and import direct routes into a dynamic routing protocol on the aggregation network. The VRRP status affects route selection of dynamic routing protocols, ensuring that the route that passes through the master ASG is always preferentially selected. In this manner, upstream and downstream traffic is transmitted along the same path. Implementation on the NGC side is similar to that on the base station side.

1.1.1.1.4 Appendix List of Port Numbers of Common Protocols

Table 1-6 Port numbers of routing protocols

Routing Protocol	UDP Port Number	TCP Port Number
RIP	520	-
RIPv2	520	-
RIPng	521	-
BGP	-	179
OSPF	-	-
IS-IS	-	-

Note that "-" indicates that the related transport layer protocol is not used.

Table 1-7 Port numbers of application layer protocols

TELNET	-	23
TFTP	69	-

Application Layer Protocol	UDP Port Number	TCP Port Number
Note that "-" indicates that the related transport layer protocol is not used.		

1.1.1.5 Terminology for IP Routing

Terms

Term	Description
ARP Vlink direct routes	IP packets are forwarded through a specified physical interface. IP packets cannot be forwarded through a VLANIF interface, because a VLANIF interface is a logical interface with several physical interfaces as its member interfaces. If an IPv4 packet reaches a VLANIF interface, the device obtains information about the physical interface using ARP and generates the relevant routing entry. The route recorded in the routing entry is called an ARP Vlink direct route.
FRR	FRR is applicable to services that are very sensitive to packet loss and delay. When a fault is detected at the lower layer, the lower layer informs the upper layer routing system of the fault. Then, the routing system forwards packets through a backup link. In this manner, the impact of the link fault on services is minimized.
NDP Vlink direct routes	IP packets are forwarded through a specified physical interface. IP packets cannot be forwarded through a VLANIF interface, because a VLANIF interface is a logical interface with several physical interfaces as its member interfaces. If an IPv6 packet reaches a VLANIF interface, the device obtains information about the physical interface using the neighbor discovery protocol (NDP) and generates the relevant routing entry. The route recorded in the routing entry is called an NDP Vlink direct route.
UNR	When a user goes online through a Layer 2 device, such as a switch, but there is no available Layer 3 interface and the user is assigned an IP address, no dynamic routing protocol can be used. To enable devices to use IP routes to forward the traffic of this user, use the Huawei User Network Route (UNR) technology to assign a route to forward the traffic of the user.

1.1.1.2 Basic IP Routing Configuration

IP routing is the basic concept on data communication networks.

1.1.1.2.1 Overview of Basic IP Routing

To forward data, routers must be capable of establishing and refreshing routing tables and forwarding datagrams based on routing tables.

Definition

As a basic concept on data communication networks, routing is the process of packet relaying or forwarding, and the process provides route information for packet forwarding.

Purpose

During data forwarding, routers, routing tables, and routing protocols are indispensable. Routing protocols are used to discover routes and contribute to the generation of routing tables. Routing tables store the routes discovered by various routing protocols, and routers select routes and implement data forwarding.

1.1.1.2.2 Configuration Precautions for Basic IP Routing

Feature Requirements

Table 1-8 Feature requirements

Feature Requirements	Series	Models
<p>Backup routes cannot be configured for mutual access between public and private networks. If backup routes are configured for public and private network routes, only the forwarding of public and private network routes is ensured. The forwarding of backup routes and the switchover between public and private network routes and their backup routes cannot be ensured.</p> <p>Plan services properly.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

1.1.1.2.3 Configuring the Router ID

The router ID uniquely identifies a device in an AS.

Usage Scenario

A router ID is a 32-bit IP address that uniquely identifies a router in an Autonomous System (AS). A router ID can be generated as follows:

- Manually configured
- Configured by the protocol
- Automatically selected

 NOTE

If the IP address of a physical interface is configured as the router ID and then the IP address changes, route flapping may occur. Therefore, configuring the IP address of a loopback interface as the router ID is recommended.

Pre-configuration Tasks

None

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **router id router-id**

The Router ID is specified.

Step 3 Run commit

The configuration is committed.

----End

Checking the Configurations

After configuring a router ID, check it.

- Run the **display router id** command to check the router ID.

1.1.1.2.4 Configuring IPv4 Multi-Topology

Multi-topology on an IPv4 network enables devices to allocate network resources more effectively.

Usage Scenario

On traditional IP networks, only one unicast forwarding table is available on the forwarding plane because only one unicast topology exists, which forces services transmitted from one router to the same destination address to share the same next hop, and various end-to-end services, such as voice and data services, to share the same physical links. As a result, some links may be heavily congested while others remain relatively idle. Deploying MT (different logical topologies) for different services on a physical network can solve the problem.

Pre-configuration Tasks

Before configuring IPv4 Multi-Topology, complete the following task:

- Configure parameters of the link layer protocol and IPv4 addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ip topology *topology-name*

A topology is created.

Step 3 Run interface *interface-type interface-name*

The view of the specified interface is displayed.

Step 4 Run ip topology *topology-name* enable

The topology is bound to the interface.

Step 5 Run commit

The configuration is committed.

----End

Checking the Configurations

Run the **display ip topology** command to check the previous configuration.

1.1.1.2.5 Configuring IPv6 Multi-Topology

Multi-topology on an IPv6 network enables devices to allocate network resources more effectively.

Usage Scenario

On traditional IPv6 networks, only one unicast forwarding table is available on the forwarding plane because only one unicast topology exists, which forces services transmitted from one router to the same destination address to share the same next hop, and various end-to-end services, such as voice and data services, to share the same physical links. As a result, some links may be heavily congested while others remain relatively idle. Deploying MT (different logical topologies) for different services on a physical network can solve the problem.

Pre-configuration Tasks

Before configuring IPv6 multi-topology, configure parameters of the link layer protocol and IPv6 addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ipv6 topology topology-name**

An IPv6 topology is created.

Step 3 Run **interface interface-type interface-name**

The view of the specified interface is displayed.

Step 4 Run **ipv6 topology topology-name enable**

The topology is bound to the interface.

Step 5 Run **commit**

The configuration is committed.

----End

Checking the Configurations

Run the **display ipv6 topology** command to check the previous configuration.

1.1.1.2.6 Configuring IPv4 FRR

IPv4 FRR is applicable to IPv4 services that are sensitive to the packet loss and delay.

Usage Scenario

Public network IPv4 FRR is applicable to services that are sensitive to packet loss or delay on the IPv4 public network.

After FRR is configured, if a fault is detected at the lower layer, the fault is reported to the upper-layer routing system. Then, packets are forwarded through a backup link, which minimizes the impact of link faults on ongoing services.

NOTICE

IPv4 FRR enables routes of different protocols to back up each other, which may result in loops.

With IP FRR, traffic is switched to a backup link if the primary link fails and switched back when the primary link recovers. If the inbound and outbound interfaces reside on different boards, packet loss may occur during the switchback. The packet loss duration varies with the service volume and CPU usage. To prevent the packet loss, perform any of the following operations:

- For IS-IS routes, run the **timer spf** command in the IS-IS view.
- For OSPF routes, run the **spf-schedule-interval** command in the OSPF view.
- For BGP routes, run the **route-select delay** command in the BGP view.

Pre-configuration Tasks

Before configuring IPv4 FRR, complete the following task:

- Configure parameters of the link layer protocol and IPv4 addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.
- Configure routes of different routing protocols but destined for the same destination address.

Enabling IPv4 FRR

Before configuring IPv4 FRR, you need to enable IPv4 FRR globally.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip frr**

IPv4 FRR is enabled.

NOTE

If IPv4 FRR is configured both in the system view and a routing protocol view, the IPv4 FRR that is configured in the routing protocol view preferentially takes effect.

Step 3 Run **commit**

The configuration is committed.

----End

(Optional) Enabling IPv4 FRR Poison Reverse

To configure IPv4 FRR on an IP ring network, you need to enable IPv4 FRR poison reverse to prevent instantaneous traffic storms during route convergence.

Context

In [Figure 1-17](#), IPv4 FRR is deployed on the IP ring network, and traffic enters the ring network from Device D and leaves the ring network from Device A. The primary and backup next hops of Device D are Device C and Device E, respectively. The primary and backup next hops of Device C are Device B and Device D, respectively. If the link between Device B and Device C fails and the traffic reaches Device C, Device C determines that the primary link fails and forwards the traffic to Device D. However, before the route convergence is complete, Device D cannot detect the link failure between Device B and Device C, and continues forwarding the traffic to Device C. As a result, an instantaneous traffic storm is generated between Device C and Device D. After Device D detects the link failure between Device B and Device C through route convergence, Device D forwards the traffic to its backup next hop (Device E). To prevent instantaneous traffic storms during route convergence and enable Device D to detect the link failure quickly, you can enable the IPv4 FRR poison reverse function. After the function is enabled, Device D searches its FIB based on the destination IP address to obtain the next hop and outbound interface+VLAN information. If the outbound interface is the primary interface and is up, Device D checks whether the outbound interface+VLAN is the same as the inbound interface+VLAN. If they are the same, Device D forwards the traffic through the backup interface. If the link between Device B and Device C fails, the traffic forwarded from Device D to Device C goes back to Device D. Device D does not send the traffic back to Device C; instead, it forwards the traffic to its backup next hop (Device E). Finally, the traffic leaves the ring network from Device A, as shown in [Figure 1-18](#).

Figure 1-17 IP ring network

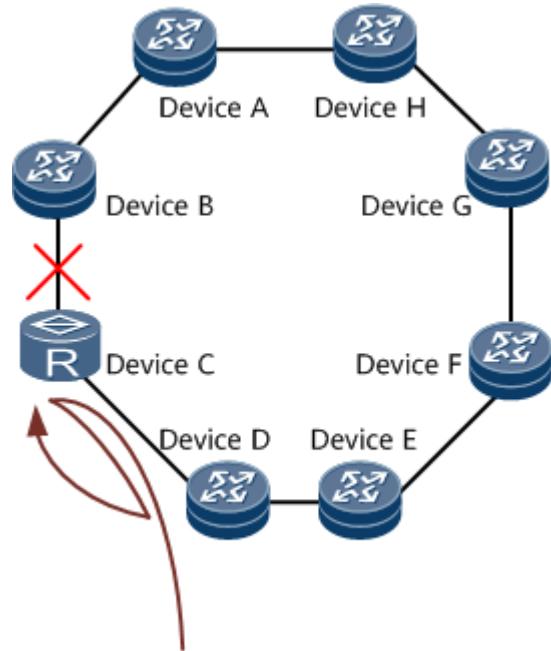

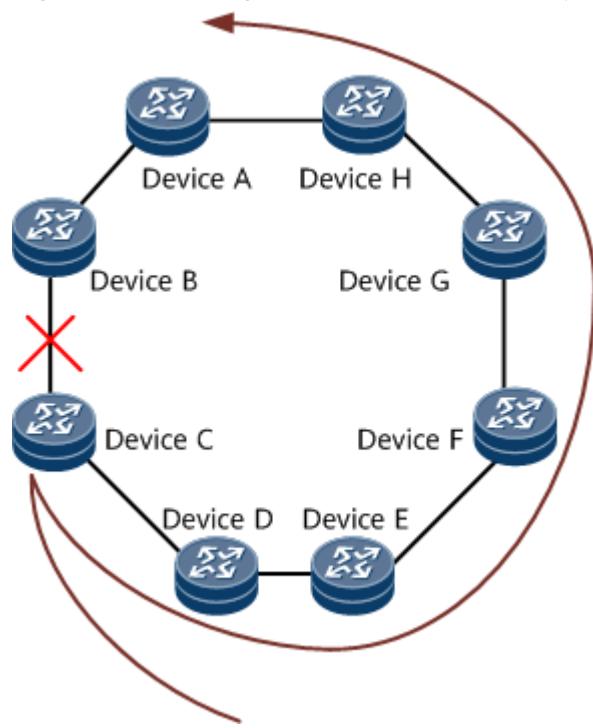

Figure 1-18 IP ring network with IPv4 FRR poison reverse enabled

Procedure

Step 1 Run `interface interface-type interface-number`

The interface view or sub-interface view is displayed.

Step 2 Run `poison-reverse enable`

IPv4 FRR poison reverse is enabled.

This command is used to prevent instantaneous traffic storms during route convergence in a scenario where IPv4 FRR is configured on an IP ring network.

Poison reverse does not support load balancing.

Step 3 Run commit

The configuration is committed.

----End

Verifying the Configuration

After configuring IPv4 FRR, you can view information about the backup outbound interfaces and backup next hops in the routing table.

Prerequisites

IPv4 FRR has been configured.

Procedure

- Run the **display ip routing-table verbose** command to check backup outbound interface and backup next hop information in the routing table.
- Run the **display ip routing-table ip-address [mask | mask-length] [longer-match] verbose** command to check backup outbound interface and backup next hop information in the routing table.
- Run the **display ip routing-table ip-address1 { mask1 | mask-length1 } ip-address2 { mask2 | mask-length2 } verbose** command to check backup outbound interface and backup next hop information in the routing table.

----End

1.1.1.2.7 Configuring IPv6 FRR

IPv6 FRR is applicable to services that are sensitive to the delay and packet loss on an IPv6 network.

Usage Scenario

Public network IPv6 FRR is applicable to services that are sensitive to the delay and packet loss on an IP public network.

After IPv6 FRR is configured, if a fault is detected at the lower layer, the fault is reported to the upper-layer routing system. Then, packets are forwarded through a backup link, which minimizes the impact of link faults on ongoing services.

NOTICE

IPv6 FRR enables routes of different protocols to back up each other, which may result in loops.

Pre-configuration Tasks

Before configuring IPv6 FRR, complete the following tasks:

- Configure parameters of the link layer protocol and IPv6 addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.
- Configure routes of different routing protocols but destined for the same destination address.

Enabling IPv6 FRR

Before configuring IPv6 FRR, you need to enable IPv6 FRR globally.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ipv6 frr

IPv6 FRR is enabled.

If IPv6 FRR is configured both in the system view and a routing protocol view, the IPv6 FRR that is configured in the routing protocol view preferentially takes effect.

Step 3 Run commit

The configuration is committed.

----End

(Optional) Enabling IPv6 FRR Poison Reverse

To configure IPv6 FRR on an IP ring network, you need to enable IPv6 FRR poison reverse to prevent instantaneous traffic storms during route convergence.

Context

In [Figure 1-19](#), IPv6 FRR is deployed on the IP ring network, and traffic enters the ring network from Device D and leaves the ring network from Device A. The primary and backup next hops of Device D are Device C and Device E, respectively. The primary and backup next hops of Device C are Device B and Device D, respectively. If the link between Device B and Device C fails and the traffic reaches Device C, Device C determines that the primary link fails and forwards the traffic to Device D. However, before the route convergence is complete, Device D cannot detect the link failure between Device B and Device C, and continues forwarding the traffic to Device C. As a result, an instantaneous traffic storm is generated between Device C and Device D. After Device D detects the link failure between Device B and Device C through route convergence, Device D forwards the traffic to its backup next hop (Device E). To prevent instantaneous traffic storms during route convergence and enable Device D to detect the link failure quickly, you can enable the IPv6 FRR poison reverse function. After the function is enabled, Device D searches its FIB based on the destination IP address to obtain the next hop and outbound interface+VLAN information. If the outbound interface is the primary

interface and is up, Device D checks whether the outbound interface+VLAN is the same as the inbound interface+VLAN. If they are the same, Device D forwards the traffic through the backup interface. If the link between Device B and Device C fails, the traffic forwarded from Device D to Device C goes back to Device D. Device D does not send the traffic back to Device C; instead, it forwards the traffic to its backup next hop (Device E). Finally, the traffic leaves the ring network from Device A, as shown in [Figure 1-20](#).

Figure 1-19 IP ring network

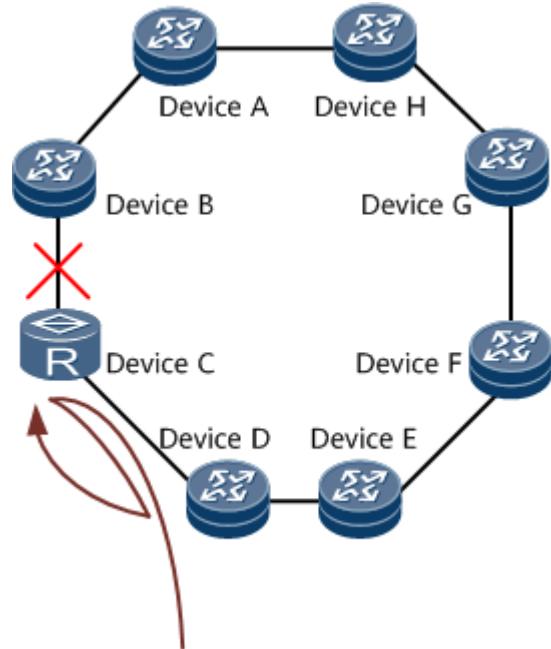

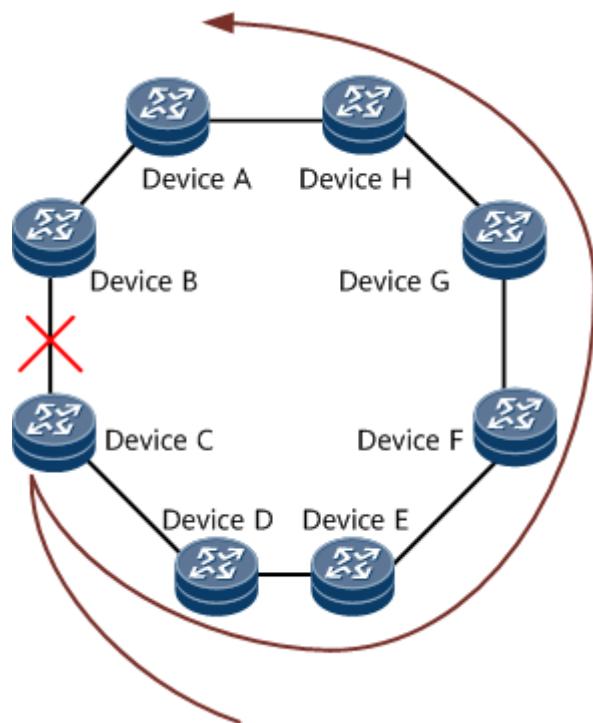

Figure 1-20 IP ring network with IPv6 FRR poison reverse enabled

Procedure

Step 1 Run **interface interface-type interface-number**

The interface view or sub-interface view is displayed.

Step 2 Run **poison-reverse enable**

IPv6 FRR poison reverse is enabled.

This command is used to prevent instantaneous traffic storms during route convergence in a scenario where IPv6 FRR is configured on an IP ring network.

Poison reverse does not support load balancing.

Step 3 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After configuring IPv6 FRR, you can view information about the backup outbound interfaces and backup next hops in the routing table.

Prerequisites

IPv6 FRR has been configured.

Procedure

- Run the **display ipv6 routing-table verbose** command to check backup outbound interface and backup next hop information in the routing table.
- Run the **display ipv6 routing-table ip-address [mask | mask-length] [longer-match] verbose** command to check backup outbound interface and backup next hop information in the routing table.
- Run the **display ipv6 routing-table ip-address1 { mask1 | mask-length1 } ip-address2 { mask2 | mask-length2 } verbose** command to check backup outbound interface and backup next hop information in the routing table.

----End

1.1.1.2.8 Configuring Route Recursion to the Default Route

When the next hop of a route is not directly reachable, you can configure route recursion to the default route.

Usage Scenario

The next hops of routes may not be directly reachable. In this case, recursion is required so that such routes can be used for traffic forwarding. To allow routes to recurse to the default route, run the **{ ip | ipv6 } route recursive-lookup default-route** command. By default, routes cannot recurse to the default route.

Pre-configuration Tasks

None

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ip route recursive-lookup default-route protocol { static | msr } or ipv6 route recursive-lookup default-route protocol { static | msr }

Route recursion to the default route is enabled.

Step 3 Run commit

The configuration is committed.

----End

Verifying the Configuration

After the configuration is complete, run the **display current-configuration** command in the system view to verify it. The command output shows that route recursion to the default route is configured.

1.1.1.2.9 Configuring the Device to Advertise Host Routes of Directly Connected Interfaces

You can configure a device to advertise the host routes of directly connected interfaces after the routes are imported by routing protocols.

Usage Scenario

By default, after a routing protocol imports host routes of directly connected interfaces, the routing protocol stores them in the routing table but does not advertise them. You can configure the device to advertise host routes of directly connected interfaces as required.

Pre-configuration Tasks

None

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ip direct-routing-table local-host-route advertise enable or ipv6 direct-routing-table local-host-route advertise enable

The device is configured to advertise host routes of directly connected interfaces.

Step 3 Run commit

The configuration is committed.

----End

Verifying the Configuration

After configuring the device to advertise host routes of directly connected interfaces, run the **display current-configuration** command in the system view. The command output shows that this function has been enabled.

1.1.1.2.10 Configuring Association Between Direct Routes and a VRRP Group

Association between direct routes and a Virtual Router Redundancy Protocol (VRRP) group ensures that both network-to-user traffic and user-to-network traffic that traverse the VRRP group travel along the same path, which facilitates network management and improves reliability.

Usage Scenario

On a live network, a VRRP group serves as a gateway for users (including common users and base stations) to access the network. User-to-network traffic traverses the master device in the VRRP group, while network-to-user traffic travels along a path that a dynamic routing protocol selects. Therefore, user-to-network traffic and network-to-user traffic may travel along different paths, which interrupts services if firewalls are attached to devices in the VRRP group, complicates traffic monitoring or statistics collection, and increases costs.

To address the preceding problems, the routing protocol is expected to select a route passing through the master device so that the user-to-network and network-to-user traffic travels along the same path. Association between direct routes and a VRRP group can meet expectations by allowing the dynamic routing protocol to select a route based on the VRRP status.

Pre-configuration Tasks

Before associating direct routes with a VRRP group, complete the following tasks:

- Configure VRRP basic functions and create a VRRP group.
- Configure a dynamic routing protocol to ensure reachable routes among nodes.

NOTE

With association between direct routes and a VRRP group, VRRP and an IGP cannot be configured on the same interface. If VRRP and an IGP are configured on the same interface, the IGP cannot inherit the route costs from the imported direct routes. As a result, the path selected by the IGP for network-to-user traffic may be different from the one on which user-to-network traffic is transmitted.

Associating Direct Routes with a VRRP Group

Associating direct routes with a VRRP group on a VRRP-enabled interface or a Loopback interface allows the interface to modify the cost of each direct route to the virtual IP network segment based on the VRRP status.

Context

If the master device in a VRRP group fails, a master/backup switchover is performed. After the master device recovers, the direct routes of the master device immediately become available. The VRRP group performs a VRRP switchback, which takes some time. To ensure that user-to-network traffic and network-to-user traffic travel along the same path in this period, associate direct routes with the VRRP group on both the master and backup devices. In this manner, the VRRP status affects the cost of the direct route to the virtual IP network segment of the VRRP group.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-name**

The interface view is displayed.

VRRP must have been configured on this interface.

Step 3 Configure the association between direct routes with the VRRP group status.

- Configure the association between IPv4 direct routes with the VRRP4 group status.
 - On non-loopback interfaces:
Run the **direct-route track vrrp vrid virtual-router-id degrade-cost cost-value** command.
 - On loopback interfaces:
Run the **direct-route track vrrp interface interface-type interface-number vrid virtual-router-id degrade-cost cost-value** command.
- To configure association between IPv6 direct routes with the VRRP6 group status, run the **direct-route ipv6 track vrrp6 vrid virtual-router-id degrade-cost cost-value** command.

After the command is run, the cost of direct routes is adjusted based on the VRRP group status, with details as follows:

- If the VRRP group status is Master, 0 (the highest priority) is used as the cost of the direct routes.
- If the VRRP group status is Backup or Initialize, the *cost-value* (greater than 0) specified in the command is used as the cost of the direct routes.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring a Dynamic Routing Protocol to Import Direct Routes

After you associate direct routes with a Virtual Router Redundancy Protocol (VRRP) group, configure a dynamic routing protocol to import the direct routes so that the path selection by the dynamic routing protocol can be controlled.

Context

After direct routes are associated with a VRRP group, VRRP-enabled devices modify the cost of each direct route to the virtual IP network segment based on the VRRP status. To control the path by a dynamic routing protocol, enable the dynamic routing protocol to import direct routes and inherit the costs from the imported direct routes.

Currently, dynamic routing protocols include the Interior Gateway Protocol (IGP) and Border Gateway Protocol (BGP). If an IGP is configured to import direct routes, routing information protocol (RIP) cannot inherit costs from the imported direct routes. This section describes how to configure Open Shortest Path First (OSPF), Intermediate System to Intermediate System (IS-IS), and BGP to import direct routes.

Procedure

- Configure OSPF to import direct routes.
 - a. Run **system-view**

The system view is displayed.
 - b. Run **ospf [process-id]**

The OSPF process view is displayed.
 - c. Run **import-route direct**

OSPF is configured to import direct routes.
 - d. Run **default cost inherit-metric**

OSPF is enabled to inherit the costs from the imported direct routes.

NOTE

- The **default (OSPF)** command has a lower priority than the **apply cost** command. If the **apply cost** command is run, it overrides the **default (OSPF)** command. Therefore, before running the **default (OSPF)** command, ensure that the **apply cost** command is not run.
- Do not run the **default cost cost-value** command after you run the **default cost inherit-metric** command. If the **default cost cost-value** command is run after the **default cost inherit-metric** command, the **default cost cost-value** command overrides the **default cost inherit-metric** command.

- e. Run **commit**

The configuration is committed.
- Configure IS-IS to import direct routes.
 - a. Run **system-view**

The system view is displayed.
 - b. Run **isis [process-id]**

The IS-IS process view is displayed.
 - c. Run **import-route direct inherit-cost**

IS-IS is configured to import direct routes and to inherit the costs from the imported direct routes.

- d. Run **commit**
The configuration is committed.
- Configure BGP to import direct routes.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **bgp as-number**
The BGP process view is displayed.
 - c. Run **import-route direct**
BGP is configured to import direct routes.
BGP automatically inherits the costs from the imported direct routes. The inherited costs are shown as the multi-exit discrimination (MED) values.
 - d. Run **commit**
The configuration is committed.

----End

Verifying the Configuration of Association Between Direct Routes and a VRRP Group

After you associate direct routes with a Virtual Router Redundancy Protocol (VRRP) group, you can view information about the VRRP group and information in the routing table of the previous-hop device on the network side.

Prerequisites

Direct routes have been associated with a VRRP group.

Procedure

- Run the **display ip routing-table** command on the backup device in the VRRP group to check the modified direct route costs in the IP routing table.
- Run the **display ip routing-table ip-address** command on the VRRP group's previous-hop device on the network side to check whether network-to-user traffic flows through the master device in the VRRP group.

----End

1.1.1.2.11 Configuring an IPv4 Direct Route to Respond to L3VE Interface Status Changes After a Delay

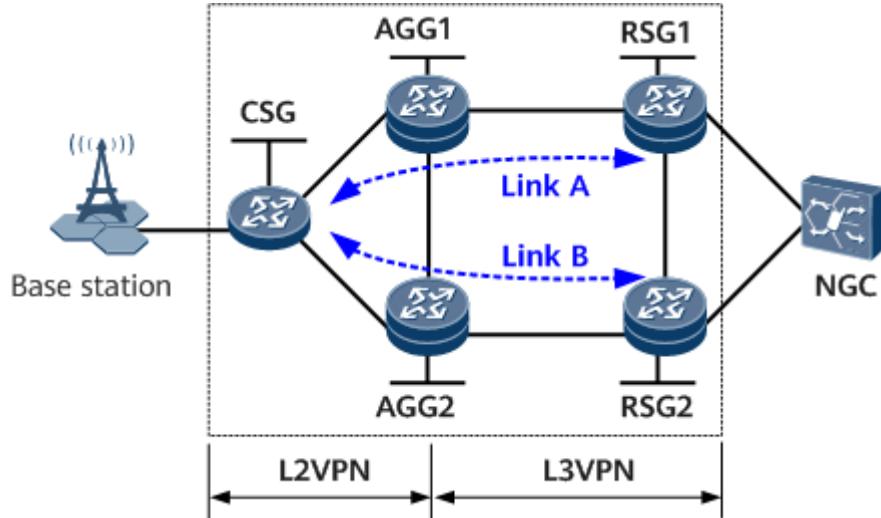

This section describes how to configure an IPv4 direct route to respond to Layer 3 virtual Ethernet (L3VE) interface status changes after a delay on an IP radio access network (RAN). During traffic switchback after the master AGG recovers, this configuration can reduce traffic loss and improve network reliability.

Usage Scenario

On the network shown in [Figure 1-21](#), a Layer 2 virtual private network (VPN) connection is set up between each AGG and the CSG through L2VE interfaces, and

Border Gateway Protocol (BGP) VPNv4 peer relationships are set up between the AGGs and RSGs on an L3VPN. L3VE interfaces are configured on the AGGs, and VPN instances are bound to the L3VE interfaces so that the CSG can access the L3VPN. BGP is configured on the AGGs to import IPv4 direct routes between the CSG and AGGs. The AGGs convert these IPv4 direct routes to BGP VPNv4 routes before advertising them to the RSGs.

Figure 1-21 Networking for the IPv4 direct route responding to L3VE interface status changes after a delay

AGG1 functions as the master device. In most cases, the RSGs select routes advertised by AGG1, and traffic travels along Link A. If AGG1 or the CSG-AGG1 link fails, traffic switches over to Link B. After AGG1 or the CSG-AGG1 link recovers, the L3VE interface on AGG1 goes from down to up, and AGG1 immediately generates an IPv4 direct route and advertises the route to the corresponding RSG. Downstream traffic then switches back to Link A. However, AGG1 has not learned the MAC address of the base station yet. As a result, downstream traffic is lost.

After a delay is configured for IPv4 direct routes to respond to L3VE interface status changes, the cost of the IPv4 direct route increases when the L3VE interface on AGG1 goes from down to up. In this case, RSGs do not preferentially select the route advertised by AGG1. Therefore, downstream traffic still travels along Link B. After the specified delay elapses, AGG1 learns the MAC address of the base station, and the cost of the IPv4 direct route restores to the default value 0. In this case, RSGs preferentially select the IPv4 direct route advertised by AGG1, preventing downstream traffic loss during switchback.

Pre-configuration Tasks

Before you configure an IPv4 direct route to respond to L3VE interface status changes after a delay, configure link-layer protocol parameters and IP addresses for interfaces and ensure that the link layer protocol of each interface is Up.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run **interface virtual-ethernet interface-number**

A VE interface is created, and the VE interface view is displayed.

Step 3 Run **ve-group ve-group-id l3-access**

The VE interface is configured as an L3VE interface for MPLS L3VPN access and bound to a VE-group.

The L2VPN can access the L3VPN only if the L2VE and L3VE interfaces are bound to the same VE-group and reside on the same board.

Step 4 Run **quit**

Return to the system view.

Step 5 Run **interface virtual-ethernet interface-number.subinterface-number**

A VE sub-interface is created, and the VE sub-interface view is displayed.

Step 6 Run **direct-route degrade-delay delay-time degrade-cost cost**

The IPv4 direct route is configured to respond to L3VE interface status changes after a delay.

After you run the **direct-route degrade-delay** command on an L3VE interface, and the L3VE interface goes from Down to Up, the cost of the L3VE interface's IPv4 direct route to the CSG is modified to the configured cost. After the configured *delay-time* expires, the IPv4 direct route cost is restored to the default value 0.

The **direct-route track pw-state**, **direct-route degrade-delay**, and **direct-route track vrrp** commands cannot all be configured on one L3VE interface. If you run the three commands on one L3VE interface, the latest configuration overrides the previous ones.

Step 7 Run **commit**

The configuration is committed.

----End

Checking the Configurations

If an AGG's L3VE interface goes from Down to Up, run the **display ip routing-table vpn-instance vpn-instance-name [ip-address] [verbose]** command on the AGG. The command output shows that the cost of the L3VE interface's IPv4 direct route to the CSG is the configured cost. After the configured *delay-time* expires, run the **display ip routing-table vpn-instance vpn-instance-name [ip-address] [verbose]** command on the AGG. The command output shows that the cost of the IPv4 direct route to the L3VE interface is the default value 0.

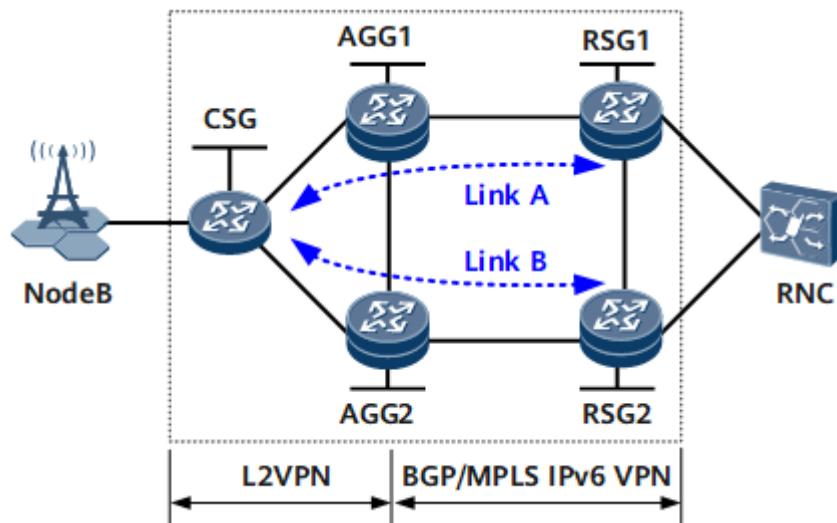

1.1.1.2.12 Configuring an IPv6 Direct Route to Respond to L3VE Interface Status Changes After a Delay

This section describes how to configure an IPv6 direct route to respond to Layer 3 Virtual Ethernet (L3VE) interface status changes after a delay. During traffic switchback after an L3VE interface recovers, this configuration can reduce traffic loss and improve network reliability.

Applicable Environment

As shown in [Figure 1-22](#), a Layer 2 virtual private network (L2VPN) connection is set up between each access aggregation gateway (AGG) and the cell site gateway (CSG) through Layer 2 Virtual Ethernet (L2VE) interfaces, while BGP virtual private network version 4 (VPNv4) peer relationships are set up between AGGs and radio network controller site gateways (RSGs) on a Layer 3 virtual private network (L3VPN). L3VE interfaces are configured on AGGs and VPN instances are bound to the L3VE interfaces, so that the CSG can access the L3VPN. BGP is configured on AGGs to import direct routes between the CSG and AGGs. These direct routes are converted to BGP VPNv6 routes and advertised to RSGs.

Figure 1-22 Networking of an IPv6 direct route responding to L3VE interface status changes after a delay

AGG1 is used as the master device in the preceding figure. In normal cases, RSGs select routes advertised by AGG1 and traffic travels along LinkA. If AGG1 or the CSG-AGG1 link fails, traffic is switched over to LinkB. After AGG1 or the CSG-AGG1 link recovers, the L3VE interface on AGG1 goes from Down to Up, and AGG1 immediately generates an IPv6 direct route destined for the CSG and advertises the route to RSGs. Downstream traffic is then switched over to LinkA. However, AGG1 has not learned the MAC addresses of the base stations yet, so downstream traffic will be lost.

After you configure a cost for an IPv6 direct route and allow the direct route to restore its default cost 0 after a delay, when the L3VE interface on AGG1 goes from Down to Up, the cost of the direct route between the CSG and AGG1 is modified to the configured cost. In this case, RSGs do not select routes advertised

by AGG1 and downstream traffic still travels along LinkB. After the configured delay expires, the cost of the direct route to the CSG is restored to the default value 0. Then, RSGs select routes advertised by AGG1 and downstream traffic is switched over to LinkA. At this time, AGG1 has learned the MAC addresses of the base stations, and downstream traffic loss will be reduced.

Pre-configuration Tasks

Before you configure an IPv6 direct route to respond to L3VE interface status changes after a delay, complete the following task:

- Configure link-layer protocol parameters and IPv6 addresses for interfaces to ensure that the link layer protocol of each interface is up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface virtual-ethernet *interface-number***

A VE interface is created, and the VE interface view is displayed.

Step 3 Run **ve-group *ve-group-id* l3-access**

The VE interface is configured as an L3VE interface and bound to a VE-group.

NOTE

The L2VPN can access the L3VPN only if the L2VE and L3VE interfaces are bound to the same VE-group and reside on the same board.

Step 4 Run **quit**

Return to the system view.

Step 5 Run **interface virtual-ethernet *interface-number*.*subinterface-number***

A VE sub-interface is created, and the VE sub-interface view is displayed.

Step 6 Run **ipv6 enable**

The IPv6 capability is enabled on the interface.

Step 7 Run **direct-route ipv6 degrade-delay *delay-time* degrade-cost *cost***

The direct route is configured to respond to L3VE interface status changes after a delay.

After you run the **direct-route ipv6 degrade-delay** command on an L3VE interface, and the L3VE interface goes from Down to Up, the cost of the L3VE interface's direct route to the CSG is modified to the configured cost. After the configured delay-time expires, the direct route cost is restored to the default value 0.

NOTE

The **direct-route ipv6 degrade-delay** command and the **direct-route ipv6 track pw-state** command cannot be all configured on one L3VE interface.

Step 8 Run commit

The configuration is committed.

----End

Checking the Configurations

If an AGG's L3VE interface goes from Down to Up, run the **display ipv6 routing-table vpn-instance vpn-instance-name [ipv6-address] [verbose]** command on the AGG. The command output shows that the cost of the L3VE interface's IPv6 direct route to the CSG is the configured cost. After the configured *delay-time* expires, run the **display ipv6 routing-table vpn-instance vpn-instance-name [ipv6-address] [verbose]** command on the AGG. The command output shows that the cost of the IPv6 direct route to the L3VE interface is the default value 0.

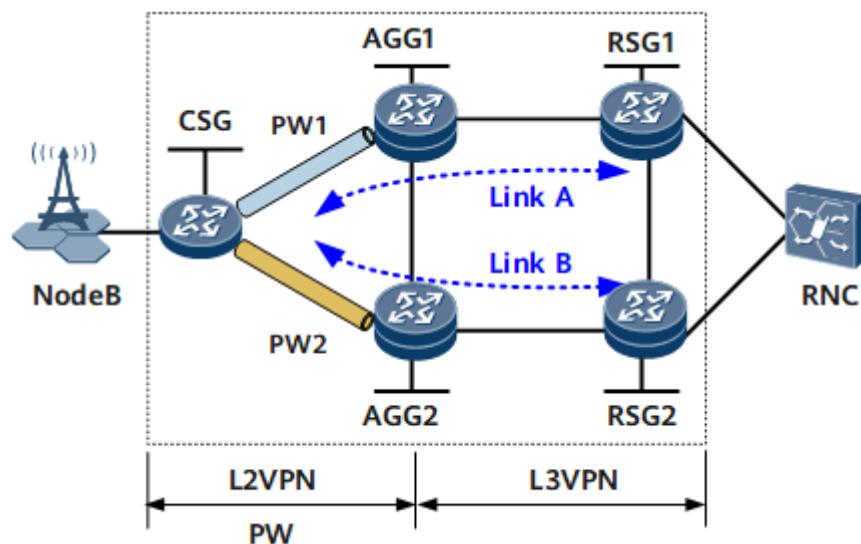

1.1.1.2.13 Configuring the Association Between the IPv4 Direct Route and PW Status

This section describes how to configure the association between the IPv4 direct route and pseudo wire (PW) status. During traffic switchback after the primary PW recovers, this configuration minimizes traffic loss and improves network reliability.

Usage Scenario

On the network shown in [Figure 1-23](#), PWs are set up between the AGGs and the CSG. Border Gateway Protocol (BGP) virtual private network version 4 (VPNv4) peer relationships are set up between the AGGs and RSGs. Layer 3 virtual Ethernet (L3VE) interfaces are configured on the AGGs, and VPN instances are bound to the L3VE interfaces so that the CSG can access the L3VPN. BGP is configured on the AGGs to import IPv4 direct routes between the CSG and AGGs. The AGGs convert these IPv4 direct routes to BGP VPNv4 routes before advertising them to the RSGs.

Figure 1-23 Networking for the association between the IPv4 direct route and PW status

AGG1 functions as the master device. In most cases, the RSGs select routes advertised by AGG1, and traffic travels along Link A. If AGG1 or the CSG-AGG1 link fails, traffic switches over to Link B. After AGG1 or the CSG-AGG1 link recovers, the L3VE interface on AGG1 goes from Down to Up, and AGG1 immediately generates an IPv4 direct route destined for the CSG and advertises the route to the RSGs. Downstream traffic then switches over to Link A. However, PW1 is on standby. As a result, downstream traffic is lost.

After you configure the association between the IPv6 direct route and PW status, when the L3VE interface on AGG1 goes from Down to Up, PW1 does not become the primary PW immediately, and the cost of the IPv6 direct route between the CSG and AGG1 increases. In this case, RSGs do not preferentially select routes advertised by AGG1 and downstream traffic still travels along LinkB. After PW1 between the CSG and AGG1 becomes the primary PW, the cost of the IPv6 direct route between the CSG and AGG1 is restored to the default value 0. Then, RSGs preferentially select routes advertised by AGG1 and downstream traffic is switched over to LinkA. At this time, AGG1 has learned the MAC addresses of the base stations, downstream traffic loss will be reduced after the traffic is switched back.

Pre-configuration Tasks

Before configuring the association between the IPv4 direct route and PW status, configure link-layer protocol parameters and IP addresses for interfaces and ensure that the link layer protocol of each interface is Up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface virtual-ethernet *interface-number***

A VE interface is created, and the VE interface view is displayed.

Step 3 Run **ve-group *ve-group-id* l3-access**

The VE interface is configured as an L3VE interface and bound to a VE-group.

The L2VPN can access the L3VPN only if the L2VE and L3VE interfaces are bound to the same VE-group and reside on the same board.

Step 4 Run **quit**

Return to the system view.

Step 5 Run **interface virtual-ethernet *interface-number*.*subinterface-number***

A VE sub-interface is created, and the VE sub-interface view is displayed.

Step 6 Run **direct-route track *pw-state* degrade-cost *cost***

The association between the IPv4 direct route and PW status is configured.

After you run the **direct-route track *pw-state*** command on an L3VE interface, the system adjusts the cost of the IPv4 direct route to the L3VE interface based on

the PW status. If the PW is on standby, the system modifies the IPv4 direct route cost to the configured value *cost*. If the PW is active, the system restores the IPv4 direct route cost to the default value 0.

 NOTE

The **direct-route track pw-state**, **direct-route degrade-delay**, and **direct-route track vrrp** commands cannot all be configured on one L3VE interface. If you run the three commands on one L3VE interface, the latest configuration overrides the previous ones.

Step 7 Run **commit**

The configuration is committed.

----End

Checking the Configurations

If a PW has recovered but has not become active, run the **display ip routing-table vpn-instance vpn-instance-name [ip-address] [verbose]** command on an AGG. The command output shows that the IPv4 direct route to the L3VE interface has the configured cost. After a PW becomes active, run the **display ip routing-table vpn-instance vpn-instance-name [ip-address] [verbose]** command on an AGG. The command output shows that the IPv4 direct route to the L3VE interface has the default cost 0.

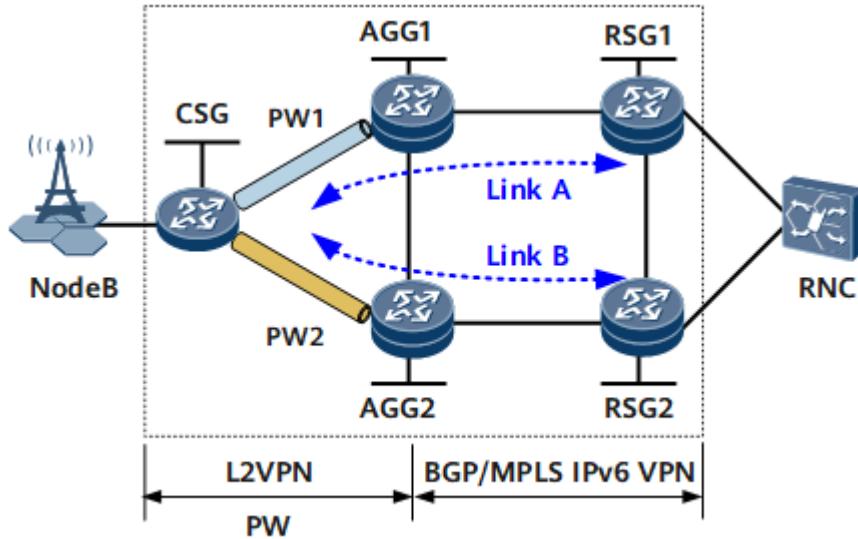

1.1.1.2.14 Configuring the Association Between the IPv6 Direct Route and PW Status

This section describes how to configure the association between the IPv6 direct route and pseudo wire (PW) status. During traffic switchback after the primary PW recovers, this configuration minimizes traffic loss and improves network reliability.

Usage Scenario

As shown in [Figure 1-24](#), PWs are set up between access aggregation gateways (AGGs) and the cell site gateway (CSG), while BGP virtual private network version 6 (VPNv6) peer relationships are set up between AGGs and radio network controller site gateways (RSGs). Layer 3 Virtual Ethernet (L3VE) interfaces are configured on AGGs and VPN instances are bound to the L3VE interfaces, so that the CSG can access the Layer 3 virtual private network (L3VPN). BGP is configured on AGGs to import IPv6 direct routes between the CSG and AGGs. These IPv6 direct routes are converted to BGP VPNv6 routes and advertised to RSGs.

Figure 1-24 Networking of the association between the IPv6 direct route and PW status

AGG1 is used as the master device in the preceding figure. In normal cases, RSGs select routes advertised by AGG1 and traffic travels along LinkA. If AGG1 or the CSG-AGG1 link fails, traffic is switched over to LinkB. After AGG1 or the CSG-AGG1 link recovers, the L3VE interface on AGG1 goes from Down to Up, and AGG1 immediately generates an IPv6 direct route destined for the CSG and advertises the route to RSGs. Downstream traffic is then switched over to LinkA. However, AGG1 has not learned the MAC addresses of the base stations yet and PW1 is standing by, so downstream traffic will be lost.

After you configure the association between the IPv6 direct route and PW status, when the L3VE interface on AGG1 goes from Down to Up, PW1 does not become the primary PW immediately, and the cost of the IPv6 direct route between the CSG and AGG1 increases. In this case, RSGs do not preferentially select routes advertised by AGG1 and downstream traffic still travels along LinkB. After PW1 between the CSG and AGG1 becomes the primary PW, the cost of the IPv6 direct route between the CSG and AGG1 is restored to the default value 0. Then, RSGs preferentially select routes advertised by AGG1 and downstream traffic is switched over to LinkA. At this time, AGG1 has learned the MAC addresses of the base stations, downstream traffic loss will be reduced after the traffic is switched back.

Pre-configuration Tasks

Before configuring the association between the IPv6 direct route and PW status, complete the following tasks:

- Configure link-layer protocol parameters and IP addresses for interfaces to ensure that the link layer protocol of each interface is up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface virtual-ethernet interface-number**

A VE interface is created, and the VE interface view is displayed.

Step 3 Run **ve-group ve-group-id l3-access**

The VE interface is configured as an L3VE interface and bound to a VE-group.

 **NOTE**

The L2VPN can access the L3VPN only if the L2VE and L3VE interfaces are bound to the same VE-group and reside on the same board.

Step 4 Run **quit**

Return to the system view.

Step 5 Run **interface virtual-ethernet interface-number.subinterface-number**

A VE sub-interface is created, and the VE sub-interface view is displayed.

Step 6 Run **ipv6 enable**

The IPv6 capability is enabled on the interface.

Step 7 Run **direct-route ipv6 track pw-state degrade-cost cost**

The association between the IPv6 direct route and PW status is configured.

After you run the **direct-route ipv6 track pw-state** command on an L3VE interface, the system adjusts the cost of the IPv6 direct route to the L3VE interface based on the PW status. If the PW is on standby, the system modifies the IPv6 direct route cost to the configured value *cost*. If the PW is active, the system restores the IPv6 direct route cost to the default value 0.

 **NOTE**

The **direct-route ipv6 track pw-state** command and the **direct-route ipv6 degrade-delay** command cannot all be configured on one L3VE interface. If you run the three commands on one L3VE interface, the latest configuration overrides the previous ones.

Step 8 Run **commit**

The configuration is committed.

----End

Checking the Configurations

If a PW has recovered but has not become active, run the **display ipv6 routing-table vpn-instance vpn-instance-name [ipv6-address] [verbose]** command on an AGG. The command output shows that the IPv6 direct route to the L3VE interface has the configured cost. After a PW becomes active, run the **display ipv6 routing-table vpn-instance vpn-instance-name [ipv6-address] [verbose]** command on an AGG. The command output shows that the IPv6 direct route to the L3VE interface has the default cost 0.

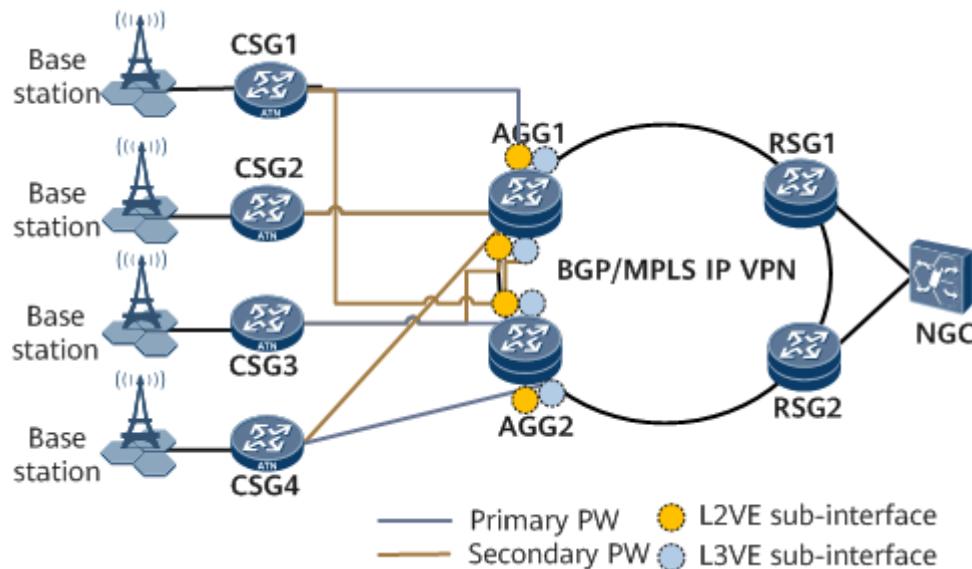

1.1.1.2.15 Configuring AGGs to Load Balance Downstream Traffic

This section describes how to configure access aggregation gateways (AGGs) to load-balance downstream traffic. The load balancing configuration can improve network resource utilization and reliability.

Usage Scenario

Figure 1-25 shows a typical networking for an L2VPN accessing an L3VPN. An L2VPN connection is set up between each AGG and CSG, whereas a BGP VPNv4 peer relationship is set up between each AGG and RSG; L3VE sub-interfaces are configured on each AGG, each L3VE sub-interface is bound to one VPN instance, and the CSGs access the L3VPN. To properly use network resources and improve network reliability, the customer requires that AGG1 forward downstream traffic destined for CSG1 and CSG2 and that AGG2 forward downstream traffic destined for CSG3 and CSG4.

Figure 1-25 Networking for an L2VPN accessing an L3VPN

To meet the preceding requirements, perform the following steps on each AGG:

1. Run the **direct-route cost** or **direct-route ipv6 cost** command to configure a cost for ARP Vlink routes and direct subnet routes on the L3VE sub-interface corresponding to the secondary PW.
2. Configure a static route to each base station and allow the static route to inherit the cost of the route to which the static route recurses.

NOTE

After this configuration is complete, each static route recurses to a direct subnet route on an L3VE interface, and the static route inherits the cost of the direct subnet route. Because the **direct-route cost** or **direct-route ipv6 cost** command is not run on the L3VE sub-interface corresponding to the primary PW, the default cost 0 is used as the cost of the generated direct routes. After a static route recurses to one of the direct routes, the cost of the static route also becomes 0.

3. Import the static routes into the BGP routing table.

 NOTE

After a static route is imported into the BGP routing table, the cost is changed to the BGP route MED. Because the costs of the static routes are different, the BGP route MED values are also different.

After the preceding configurations are complete, each AGG advertises the routes destined for base stations to its VPNV4 peer (RSG). The RSG can then select routes based on MED values. For routes with the same prefix advertised by AGG1 and AGG2, RSGs select the routes advertised by AGG1 as the primary routes to CSG1 and CSG2 and the routes advertised by AGG2 as the primary routes to CSG3 and CSG4. In this manner, downstream traffic is load balanced between AGGs.

Pre-configuration Tasks

Before configuring AGGs to load-balance downstream traffic, configure link-layer protocol parameters and IP addresses for interfaces and ensure that the link layer protocol on each interface is up.

Procedure

Step 1 Set a cost for routes to the directly connected network segment.

1. Run **interface virtual-ethernet *interface-number***

A VE interface is created, and the VE interface view is displayed.

2. Run **ve-group *ve-group-id* l3-access**

The VE interface is configured as an L3VE interface that accesses a BGP/MPLS IP VPN and bound to a VE-group.

 NOTE

L2VPN access can be implemented only if the L2VE and L3VE interfaces are bound to the same VE-group and reside on the same board.

3. Run **quit**

Return to the system view.

4. Run **interface virtual-ethernet *interface-number*.*subinterface-number***

A VE sub-interface is created, and the VE sub-interface view is displayed.

5. Run **direct-route cost *cost* or direct-route ipv6 cost *cost***

A cost is configured for direct subnet routes on the L3VE sub-interface.

6. Run **quit**

Return to the system view.

Step 2 Run **ip route-static vpn-instance *vpn-source-name* destination-address { mask | mask-length } nexthop-address [preference *preference* | tag *tag*] * inherit-cost [description *text*]**

A static route is configured for the VPN instance, and the static route is configured to inherit the cost of the recursive route.

vpn-source-name specifies the name of the VPN instance bound to the L3VE sub-interface. *nexthop-address* specifies the IP address of the interface connecting the base station to the AGG.

Step 3 Perform either of the following operations to configure BGP to import static routes. After the configuration is complete, the costs of the static routes are changed to the MED values of BGP routes.

- To import static routes to the BGP routing table automatically, run the **import-route static** command.
- To import static routes to the BGP routing table manually, run the **network** command.

If you run the **import-route static** command, some unneeded static routes may be imported to the BGP routing table. To import a static route with a specific prefix and mask to the BGP routing table, run the **network** command.

Step 4 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After the configuration is complete, if the L3VE sub-interface is up, run the **display ip routing-table vpn-instance *vpn-instance-name* [*ip-address*] [verbose]** or **display ipv6 routing-table vpn-instance *vpn-instance-name* [*ip-address*] [verbose]** command on the AGG. The command output shows that the cost of direct subnet routes on the L3VE sub-interface is changed to the configured cost.

1.1.1.2.16 Configuring the Advertisement of Public Network IPv4 ARP Vlink Direct Routes

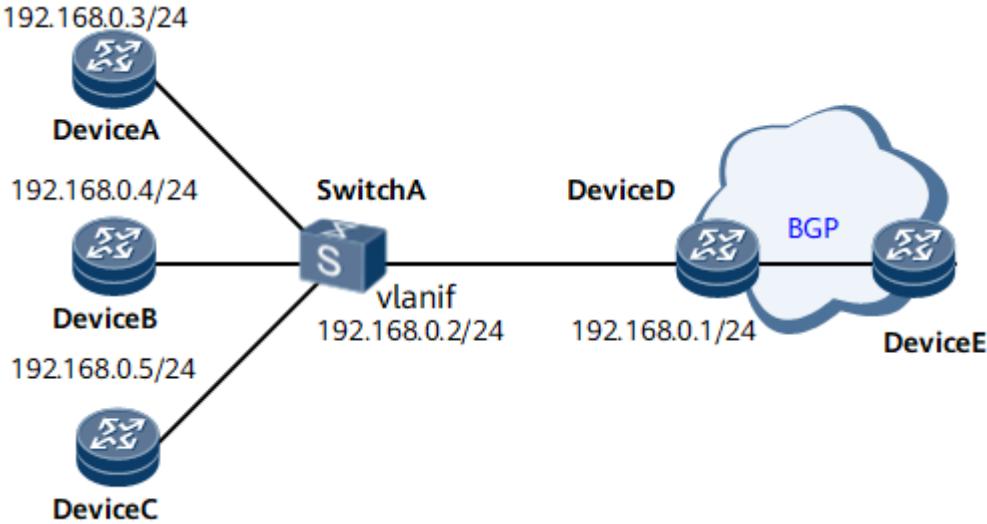

On an IPv4 network, advertising public network IPv4 ARP Vlink direct routes helps with precise control of data traffic.

Usage Scenario

Layer 3 IP forwarding requires physical interfaces to be specified. In a VLAN environment, however, such forwarding cannot be implemented through logical interfaces. Therefore, Layer 3 interfaces of VLAN users need to be obtained through ARP and routing entries containing Layer 3 interface information needs to be generated. Such routes are called IPv4 ARP Vlink direct routes.

As shown in **Figure 1-26**, DeviceD uses logical interfaces to connect to Devices A, B, and C at three sites. DeviceE only needs to communicate with DeviceB, but not with DeviceA or DeviceC. You can configure DeviceD to advertise IPv4 ARP Vlink direct routes and configure a route-policy on DeviceD to filter out routes to the network segment of the VLAN for which the logical interfaces are configured and filter out routes to DeviceA and DeviceC.

Figure 1-26 Networking diagram of advertising IPv4 ARP Vlink direct routes on the public network

Before IPv4 ARP Vlink direct routes are advertised, a route-policy can be configured to filter the advertised routes and only routes that match the route-policy can be advertised. In this manner, data traffic can be precisely controlled.

Perform the following steps on the router on which IPv4 ARP Vlink direct routes need to be advertised.

Pre-configuration Tasks

Before advertising IPv4 ARP Vlink direct routes on the public network, configure parameters of a link layer protocol and assign an IP address to each interface to ensure that the link layer protocol on the interfaces is Up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **arp vlink-direct-route advertise [route-policy route-policy-name | route-filter route-filter-name]**

Advertisement of public network IPv4 ARP Vlink direct routes is configured.

To filter the routes, you can specify **route-policy route-policy-name** or **route-filter route-filter-name**.

NOTE

Currently, apply clauses cannot be used to set route attributes for matched ARP Vlink direct routes.

After the device is enabled to advertise IPv4 ARP Vlink direct routes, such routes can be advertised only after they are imported to the routing table of a dynamic

routing protocol. Perform any of the following operations based on the routing protocol on the router:

- To import IPv4 ARP Vlink direct routes to RIP, run the **import-route direct [cost cost | route-policy route-policy-name]** * command, and then configure advertisement.
- To import IPv4 ARP Vlink direct routes to OSPF, run the **import-route direct [cost cost | route-policy route-policy-name | tag tag | type type]** * command, and then configure advertisement.
- To import IPv4 ARP Vlink direct routes to IS-IS, run the **import-route direct [cost-type { external | internal } | cost cost | tag tag | route-policy route-policy-name | [level-1 | level-2 | level-1-2]]** * command, and then configure advertisement.
- To import IPv4 ARP Vlink direct routes to BGP, run the **import-route direct [med med | route-policy route-policy-name]** * command, and then configure advertisement.

Step 3 (Optional) Run **interface interface-type interface-number**

The interface view is displayed.

Step 4 (Optional) Run **arp vlink-direct-route preference preference-value**

A preference is configured for ARP Vlink direct routes.

Step 5 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After configuring advertisement of public network IPv4 ARP Vlink direct routes, run the **display ip routing-table verbose** command to check public network IPv4 ARP Vlink direct routes.

1.1.1.2.17 Configuring the Advertisement of IPv6 NDP Vlink Direct Routes on the Public Network

On an IPv6 public network, advertising IPv6 neighbor discover protocol (NDP) Vlink direct routes allows precise control of data traffic.

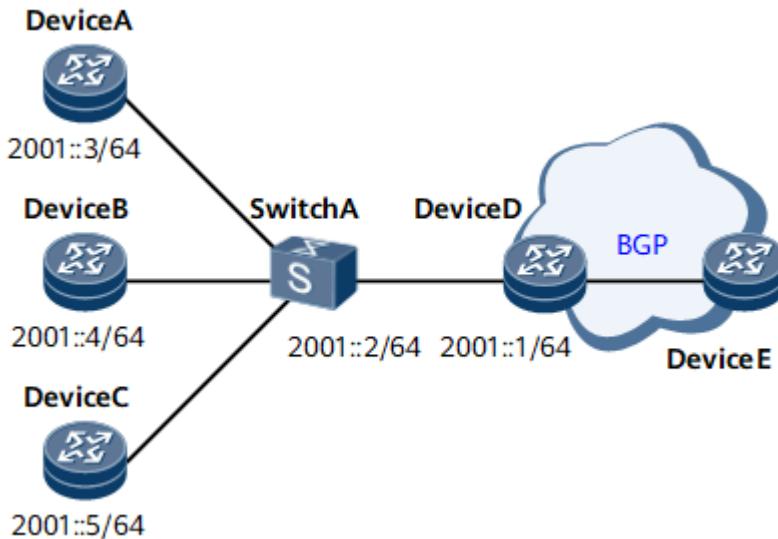

Applicable Environment

IP packets are forwarded through a specified physical interface, but cannot be forwarded through a logical interface. If packets reach a logical interface, the device obtains information about the layer-3 interfaces using IPv6 NDP and generates relevant routing entries. The routes recorded by the routing entries are called IPv6 NDP Vlink direct routes.

As shown in [Figure 1-27](#), Device D uses logical interfaces to connect to Devices A, B, and C at three sites. Device E only needs to communicate with Device B, but not with Device A and Device C. You can configure Device D to advertise IPv6 NDP Vlink direct routes and configure a route-policy on Device D to filter out routes to

the network segment of the VLAN for which the logical interfaces are configured and filter out routes to Device A and Device C.

Figure 1-27 Networking diagram of advertising IPv6 NDP Vlink direct routes on the public network

Before IPv6 NDP Vlink direct routes are advertised, a route-policy can be used to filter the advertised routes and only routes that pass the filtering can be advertised. In this manner, data traffic can be precisely controlled.

Perform the following steps on the router on which IPv6 NDP Vlink direct routes need to be advertised.

Pre-configuration Tasks

Before advertising IPv6 NDP Vlink direct routes on the public network, complete the following task:

- Configuring parameters of a link layer protocol and assigning an IP address to each interface to ensure that the link layer protocol on the interfaces is Up

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run **ipv6 nd vlink-direct-route advertise [route-policy route-policy-name | route-filter route-filter-name]**

Advertising IPv6 NDP Vlink direct routes is enabled.

If IPv6 NDP Vlink direct routes have to be advertised, you can specify the parameter **route-policy route-policy-name** or **route-filter route-filter-name** in the **ipv6 nd vlink-direct-route advertise** command to filter IPv4 ARP Vlink direct routes.

 NOTE

At present, **apply** clauses cannot be used to set routing attributes for the NDP Vlink direct routes that match the filtering rules.

Step 3 Run commit

The configuration is committed.

After advertising IPv6 NDP Vlink direct routes is enabled, IPv6 NDP Vlink direct routes can be advertised only if they are imported to dynamic routing protocols. Perform the following steps on the router based on the type of the dynamic routing protocol:

- If RIPng is used, run the **import-route direct [cost cost | route-policy route-policy-name]** * command to import IPv6 NDP Vlink direct routes to RIPng.
- If OSPFv3 is used, run the **import-route direct [cost cost | inherit-cost | route-policy route-policy-name | tag tag | type type]** * command to import IPv6 NDP Vlink direct routes to OSPFv3.
- If IS-IS is used, run the **import-route direct [cost-type { external | internal } | cost cost | tag tag | route-policy route-policy-name | [level-1 | level-2 | level-1-2]]** * command to import IPv6 NDP Vlink direct routes to IS-IS.
- If BGP4+ is used, run the **import-route direct [med med | route-policy route-policy-name]** * command to import IPv6 NDP Vlink direct routes to BGP4+.

----End

Checking the Configurations

Run the **display ipv6 routing-table ipv6-address [prefix-length] [longer-match] [verbose]** command to check information about advertised IPv6 NDP Vlink direct routes on the public network.

1.1.1.2.18 Configuring the Device to Filter ARP or ND Entries When Advertising VPN Vlink Direct Routes

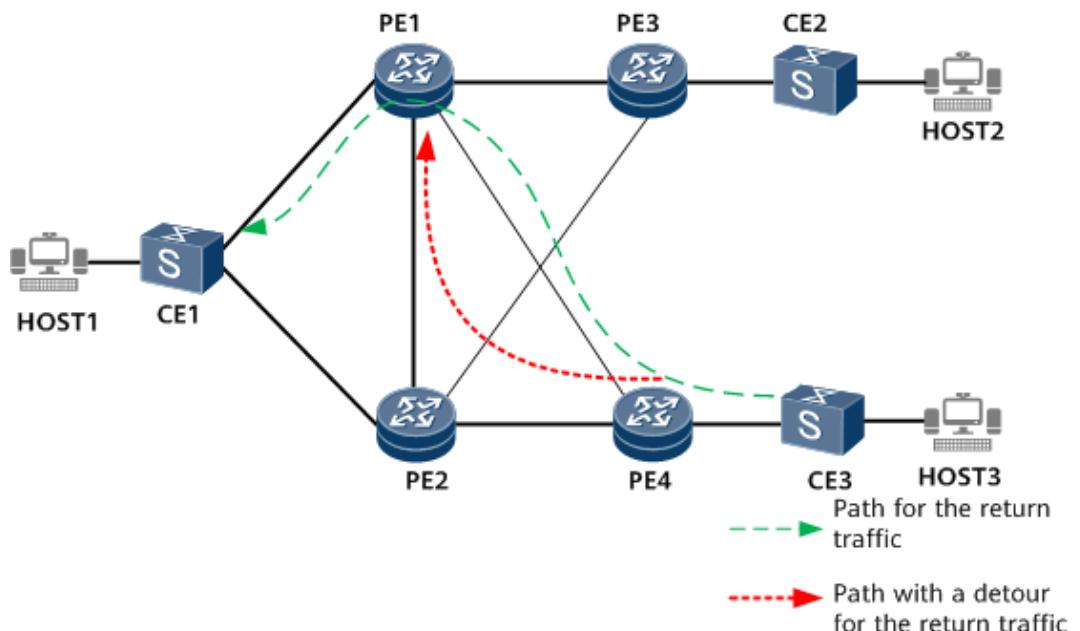

This section describes how to configure a device to filter ARP or ND entries when advertising VPN Vlink direct routes in a scenario where EVPN and L3VPN coexist. This configuration prevents the device from advertising the routes generated based on the ARP or ND entries that are filtered out.

Usage Scenario

During network evolution, some devices may be EVPN-ready, whereas other devices support only traditional functions, such as L3VPN, but not yet EVPN-ready. For example, on the network shown in [Figure 1-28](#), CE1, CE2, and CE3 are access devices at different sites. CE1 is dual-homed to gateway devices PE1 and PE2. PE1, PE2, and PE3 are EVPN-ready gateways, whereas PE4 is still a traditional device. PE1, PE2, and PE3 run EVPN and implement Layer 2 and Layer 3 service interworking for the access devices. In addition, PE1, PE2, and PE4 run traditional L2VPN and L3VPN and implement Layer 2 and Layer 3 service interworking for the access devices. CE1 accesses PE1 and PE2 through Layer 2 sub-interfaces, and the same gateway address is configured for corresponding VBDIF interfaces on

PE1 and PE2. CE1 accesses PE1 and PE2 in dual-homing single-active mode. PE1 is the master device, whereas PE2 is the backup device. PE1 learns the dynamic ARP entry of HOST1 and sends the ARP entry to PE2 through an EVPN IRB route for backup. PE2 then generates a remote dynamic ARP entry of HOST1. PE1 and PE2 generate Vlink routes based on the ARP entries and send VPNv4 host routes to PE4. After receiving these routes, PE4 selects one of them based on route priorities. If the route received from PE2 is selected, traffic travels along the path CE3 -> PE4 -> PE2 -> PE1 -> CE1 (with a detour to PE2) for a long time. Because EVPN does not generate IRB routes based on remote dynamic ARP entries, PE3 can receive the EVPN IRB route only from PE1, and the route is used to guide Layer 3 forwarding. Therefore, traffic from CE2 to CE1 passes through CE2 -> PE3 -> PE1 -> CE1, without a detour to PE2. To prevent a detour, configure PE2 to filter out single-active and redirection ARP entries so that it does not advertise the routes generated based on these entries. In this way, PE4 will not receive the route advertised by PE2, preventing return traffic from detouring to PE2.

Figure 1-28 Coexistence of EVPN dual-homing single-active and L3VPN

Procedure

- Enable the device to filter ARP entries when advertising Vlink routes.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **ip vpn-instance *vpn-instance-name***
A VPN instance is created and its view is displayed.
 - c. Run **ipv4-family**
The IPv4 address family is enabled for the VPN instance, and the VPN instance IPv4 address family view is displayed.
 - d. Run **arp vlink-direct-route advertise-filter single-active-redirect**
The device is enabled to filter ARP entries when advertising Vlink routes.

e. Run **commit**

The configuration is committed.

- Enable the device to filter ND entries when advertising Vlink routes.

a. Run **system-view**

The system view is displayed.

b. Run **ip vpn-instance *vpn-instance-name***

A VPN instance is created and its view is displayed.

c. Run **ipv6-family**

The IPv6 address family is enabled for the VPN instance, and the VPN instance IPv6 address family view is displayed.

d. Run **nd vlink-direct-route advertise-filter single-active-redirect**

The device is enabled to filter ND entries when advertising Vlink routes.

e. Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After enabling the device to filter ARP entries when advertising Vlink routes, run the **display ip routing-table all-vpn-instance verbose** command to check information about VPN Vlink direct routes.

After enabling the device to filter ND entries when advertising Vlink routes, run the **display ipv6 routing-table all-vpn-instance verbose** command to check information about VPN Vlink direct routes.

1.1.1.2.19 Configuring the Association Between IPv4 Direct Routes and IPsec Instance Status

The association between IPv4 direct routes and IP security (IPsec) instance status ensures that data encrypted using IPsec can be transmitted to the correct radio network controller site gateway (RSG).

Usage Scenario

In an IP radio access network (IPRAN) scenario, some services require high security. To meet such requirements, cell site gateways (CSGs) encrypt data of these services using IPsec. After the data flows to RSGs (IPsec gateways) through an IPsec tunnel, the RSGs decrypt the data. In most cases, carriers deploy master and backup RSGs and configure the same IP address for the IPsec tunnel interfaces of the master and backup RSGs to improve network reliability.

Without the association between IPv4 direct routes and IPsec instance status, IPv4 direct routes with the same prefix generated on the IPsec tunnel interfaces of the master and backup RSGs share the same default cost (0). As a result, after receiving these routes from the master and backup RSGs, CSGs cannot select an optimal one based on the cost.

With the association between IPv4 direct routes and IPsec instance status:

- If the IPsec instance status is master on an IPsec tunnel interface, the cost of the IPv4 direct routes generated on the interface is 0.
- If the IPsec instance status is backup on an IPsec tunnel interface or the system cannot detect the IPsec instance status, the cost of the IPv4 direct routes generated on the interface is the cost configured on the interface.

After receiving the IPv4 direct routes with the same prefix from the master and backup RSGs, CSGs can select an optimal one based on the cost. Therefore, the CSGs can transmit data encrypted using IPsec to the correct RSG.

Pre-configuration Tasks

Before configuring the association between IPv4 direct routes and IPsec instance status, complete the following tasks:

- Configure link layer protocol parameters and IP addresses for interfaces and ensure that the link layer protocol of each interface is Up.
- Configure IPsec.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface tunnel *interface-number***

A tunnel interface is created, and the tunnel interface view is displayed.

Step 3 Run **tunnel-protocol ipsec**

The encapsulation protocol is set to IPsec on the tunnel interface.

Step 4 Run **ipsec policy *policy-name* service-instance-group *service-group-name* instance *instance-id***

The IPsec policy is applied on the interface.

Step 5 Run **direct-route track ipsec-instance degrade-cost *cost***

The association between IPv4 direct routes and IPsec instance status is configured.

If the IPsec tunnel interface uses the IP address of another interface, the association between the cost of IPv4 direct routes and the IPsec instance status cannot be configured on this IPsec tunnel interface.

The cost of local IPv4 direct routes that are not to be advertised cannot be associated with the IPsec instance status.

Step 6 Run **commit**

The configuration is committed.

----End

Checking the Configurations

After configuring association between IPv4 direct routes and IPsec instance status, run the **display ip routing-table vpn-instance vpn-instance-name [ip-address] [verbose]** command on the RSG to check the information about the IP routing table of the VPN instance or run the **display ip routing-table [ip-address [mask | mask-length] [verbose]]** command to check the information about the IP routing table of the public network instance.

- If the IPsec instance status is master on an IPsec tunnel interface, the cost of the IPv4 direct routes generated on the interface is 0.
- If the IPsec instance status is backup on an IPsec tunnel interface or the system cannot detect the IPsec instance status, the cost of the IPv4 direct routes generated on the interface is the cost configured on the interface.

1.1.1.2.20 Configuring Route or Tunnel Recursion Suppression in Case of Flapping

Usage Scenario

In route or tunnel recursion scenarios, if a route or tunnel flaps frequently, services that depend on the route or tunnel perform recursion frequently, causing frequent route updates. As a result, the CPU usage of the system keeps increasing. To solve the problem, enable route or tunnel recursion suppression in case of flapping. The suppression reduces the route update frequency and the CPU usage. To configure suppression periods for route or tunnel recursion, run the **route recursive-lookup delay** command.

Pre-configuration Tasks

Before configuring route or tunnel recursion suppression in case of flapping, complete the following tasks:

- Configure link layer protocol parameters and IPv4 addresses for interfaces and ensure that the link layer protocol of the interfaces is Up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **undo route recursive-lookup delay disable**

Route or tunnel recursion suppression in case of flapping is enabled.

To disable route or tunnel recursion suppression in case of flapping, run the **route recursive-lookup delay disable** command.

Step 3 (Optional) Run **route recursive-lookup delay start-time start-time increase-time increase-time max-time max-time**

Suppression periods are configured for route or tunnel recursion, including the initial suppression period, incremental suppression period since the second suppression, and the maximum suppression period.

Step 4 Run **commit**

The configuration is committed.

----End

Checking the Configurations

Run the **display current-configuration | include route recursive-lookup delay** command to check configurations.

1.1.1.2.21 Maintaining IP Routes

Maintaining IP routes involves displaying the routing table and routing management module, and debugging the routing management module.

Displaying the Routing Table

Viewing information about the routing table helps locate faults on the network.

Context

It is necessary to check the information in the routing table using **display** commands in order to locate routing problems. The **display** commands can be used in all views. Common commands for displaying routing information are listed as follows:

Procedure

- To check brief information about activated routes in the IP routing table, run the **display ip routing-table** command.
- To check detailed information about the IP routing table, run the **display ip routing-table verbose** command.
- To check limits on the number of routes and prefixes, run the **display ip routing-table limit [all-vpn-instance | vpn-instance vpn-instance-name]** command.
- To check the number of routes, run the **display ip routing-table route-number** command.
- To check the route to the specified destination IP address, run the **display ip routing-table ip-address [mask | mask-length] [longer-match] [verbose]** command.
- To check routes to the specified range of destination IP addresses, run the **display ip routing-table ip-address1 { mask1 | mask-length1 } ip-address2 { mask2 | mask-length2 } [verbose]** command.
- To check the routes discovered by the specified protocol, run the **display ip routing-table protocol { direct | ospf | isis | static | rip | bgp | unr } [inactive | verbose]** command.
- To check general information about the routing table, run the **display ip routing-table statistics** command.
- To check brief information about the VPN routing table, run the **display ip routing-table vpn-instance vpn-instance-name** command.
- To check detailed information about the VPN routing table, run the **display ip routing-table vpn-instance vpn-instance-name verbose** command.

- To check detailed information about the route to the specified destination IP address in the VPN routing table, run the **display ip routing-table vpn-instance vpn-instance-name ip-address [mask | mask-length] [longer-match] [verbose]** command.
- To check detailed information about the routes to the specified network segment in the VPN routing table, run the **display ip routing-table vpn-instance vpn-instance-name ip-address1 { mask1 | mask-length1 } ip-address2 { mask2 | mask-length2 } [verbose]** command.
- To check brief information about activated routes in the IPv6 routing table, run the **display ipv6 routing-table** command.
- To check detailed information about the IPv6 routing table, run the **display ipv6 routing-table verbose** command.
- To check brief information about the IPv6 routing table, run the **display ipv6 routing-table [vpn-instance vpn-instance-name] simple** command.
- To check limits on the number of IPv6 routes and prefixes, run the **display ipv6 routing-table limit [all-vpn-instance | vpn-instance vpn-instance-name]** command.
- To check the number of IPv6 routes, run the **display ipv6 routing-table route-number** command.
- To check the route to the specified destination IPv6 address, run the **display ipv6 routing-table ipv6-address [prefix-length] [longer-match] [verbose]** command.
- To check routes to the specified range of destination IPv6 addresses, run the **display ipv6 routing-table ipv6-address1 [prefix-length1] ipv6-address2 prefix-length2 [verbose]** command.
- To check the IPv6 routes discovered by the specified protocol, run the **display ipv6 routing-table protocol { bgp | direct | isis | ospfv3 | ripng | static | unr } [inactive | verbose]** command.
- To check general information about the IPv6 routing table, run the **display ipv6 routing-table statistics** command.
- To check brief information about the VPN routing table, run the **display ipv6 routing-table vpn-instance vpn-instance-name** command.
- To check detailed information about the VPN routing table, run the **display ipv6 routing-table vpn-instance vpn-instance-name verbose** command.
- To check detailed information about the route to the specified destination IPv6 address in the VPN routing table, run the **display ipv6 routing-table vpn-instance vpn-instance-name ipv6-address [prefix-length] [longer-match] [verbose]** command.
- To check detailed information about the routes to the specified IPv6 network segment in the VPN routing table, run the **display ipv6 routing-table vpn-instance vpn-instance-name ipv6-address1 [prefix-length1] ipv6-address2 prefix-length2 [verbose]** command.

----End

Clearing Routing Table Statistics

Clear historical statistics about protocol routes in the IPv4 and IPv6 routing table. This enables the router to re-collect statistics about protocol routes, facilitating route monitoring and fault location.

Context

NOTICE

Statistics in the IPv4 and IPv6 routing table cannot be restored after you clear them. Therefore, exercise caution when running the command.

Procedure

- To clear statistics about protocol routes in the IPv4 routing table, run the **reset ip routing-table statistics protocol** command in the user view.
- To clear statistics about protocol routes in the IPv6 routing table, run the **reset ipv6 routing-table statistics protocol** command in the user view.

----End

Configuring a Limit on the Number of IPv4 Public Route Prefixes

Configuring a limit on the number of IPv4 public route prefixes can improve system security and reliability.

Context

If the router imports a large number of routes, system performance may be affected when processing services because the routes consume a lot of system resources. To improve system security and reliability, configure a limit on the number of IPv4 public route prefixes. When the number of IPv4 public route prefixes exceeds the limit, an alarm is generated, prompting you to check whether unneeded IPv4 public route prefixes exist.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip prefix-limit number { alert-percent [route-unchanged] | simply-alert }**

A limit is configured on the number of IPv4 public route prefixes.

If you decrease *alert-percent* after the number of IPv4 public route prefixes exceeds *number*, whether the routing table remains unchanged is determined by **route-unchanged**.

- If you specify **route-unchanged** in the command, the routing table remains unchanged.
- If you do not specify **route-unchanged** in the command, the system deletes the routes from the routing table and re-adds routes.

By default, the system deletes the routes from the routing table and re-adds routes.

 NOTE

After the number of IPv4 public route prefixes exceeds the limit, note the following rules:

- If you run the **ip prefix-limit** command to increase *number* or the **undo ip prefix-limit** command to delete the limit, the router relearns IPv4 public route prefixes.
- You can use **display ip routing-table limit [all-vpn-instance | vpn-instance *vpn-instance-name*]** command to display limits on the number of routes and prefixes.
- Direct and static routes can still be added to the IP routing table.

Step 3 Run commit

The configuration is committed.

----End

Configuring a Limit on the Number of IPv6 Public Route Prefixes

Configuring a limit on the number of IPv6 public route prefixes can improve system security and reliability.

Context

If the router imports a large number of routes, system performance may be affected when processing services because the routes consume a lot of system resources. To improve system security and reliability, configure a limit on the number of IPv6 public route prefixes. When the number of IPv6 public route prefixes exceeds the limit, an alarm is generated, prompting you to check whether unneeded IPv6 public route prefixes exist.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run **ipv6 prefix-limit *number* { *alert-percent* [**route-unchanged] | **simply-alert** }****

A limit is configured on the number of IPv6 public route prefixes.

If you decrease *alert-percent* after the number of IPv6 public route prefixes exceeds *number*, whether the routing table remains unchanged is determined by **route-unchanged**.

- If you specify **route-unchanged** in the command, the routing table remains unchanged.
- If you do not specify **route-unchanged** in the command, the system deletes the routes from the routing table and re-adds routes.

By default, the system deletes the routes from the routing table and re-adds routes.

 NOTE

After the number of IPv6 public route prefixes exceeds the limit, note the following rules:

- If you run the **ipv6 prefix-limit** command to increase *number* or the **undo ipv6 prefix-limit** command to delete the limit, the router relearns IPv6 public route prefixes.
- You can use **display ipv6 routing-table limit [all-vpn-instance | vpn-instance *vpn-instance-name*]** command to display limits on the number of routes and prefixes.
- Direct and static routes can still be added to the IP routing table.

Step 3 Run commit

The configuration is committed.

----End

Configuring Thresholds for the Number of IPv4 Route Prefixes

This section describes how to configure thresholds (one alarm threshold and one clear alarm threshold) for the number of IPv4 route prefixes on a device. After the thresholds are configured, an alarm is generated when the number of IPv4 route prefixes on the device exceeds the alarm threshold, and the alarm is cleared when the number of IPv4 route prefixes falls below the clear alarm threshold.

Configuring these thresholds facilitates maintenance.

Context

The number of IPv4 route prefixes that can be added to a routing table is limited. If the number exceeds the limit, new prefixes cannot be added to the routing table, which may interrupt services. To address this problem, configure an alarm threshold for the number of IPv4 route prefixes.

An alarm is generated when the following conditions are met:

- The number of IPv4 route prefixes on the device exceeds the alarm threshold.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ip prefix-limit system threshold-alarm upper-limit *upper-limit-value* lower-limit *lower-limit-value*

Two thresholds (one alarm threshold and one clear alarm threshold) are configured for the number of IPv4 route prefixes on the device.

 NOTE

When you configure *upper-limit-value* and *lower-limit-value*, note the following suggestions:

- Set a value less than or equal to 95 for *upper-limit-value*.
- *lower-limit-value* must be less than *upper-limit-value*. Set *lower-limit-value* to a value at least 10 less than *upper-limit-value* to prevent alarms from being frequently generated and cleared due to route flapping.

Step 3 Run commit

The configuration is committed.

----End

Configuring Thresholds for the Number of IPv6 Route Prefixes

This section describes how to configure thresholds (one alarm threshold and one clear alarm threshold) for the number of IPv6 route prefixes on a device. After the thresholds are configured, an alarm is generated when the number of IPv6 route prefixes on the device exceeds the alarm threshold, and the alarm is cleared when the number of IPv6 route prefixes falls below the clear alarm threshold.

Configuring these thresholds facilitates maintenance.

Context

The number of IPv6 route prefixes that can be added to a routing table is limited. If the number exceeds the limit, new prefixes cannot be added to the routing table, which may interrupt services. To address this problem, configure an alarm threshold for the number of IPv6 route prefixes.

An alarm is generated when the following conditions are met:

- The number of IPv6 route prefixes on the device exceeds the alarm threshold.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run **ipv6 prefix-limit system threshold-alarm upper-limit *upper-limit-value* lower-limit *lower-limit-value***

Two thresholds (one alarm threshold and one clear alarm threshold) are configured for the number of IPv6 route prefixes on the device.

When you configure *upper-limit-value* and *lower-limit-value*, note the following suggestions:

- Set a value less than or equal to 95 for *upper-limit-value*.
- *lower-limit-value* must be less than *upper-limit-value*. Set *lower-limit-value* to a value at least 10 less than *upper-limit-value* to prevent alarms from being frequently generated and cleared due to route flapping.

Step 3 Run commit

The configuration is committed.

1.1.1.2.22 Configuration Examples for IP Routing Basis

This section describes several configuration examples.

Example for Configuring Public Network IPv4 FRR

With public network IPv4 FRR, traffic can be rapidly switched to a backup link if the primary link fails.

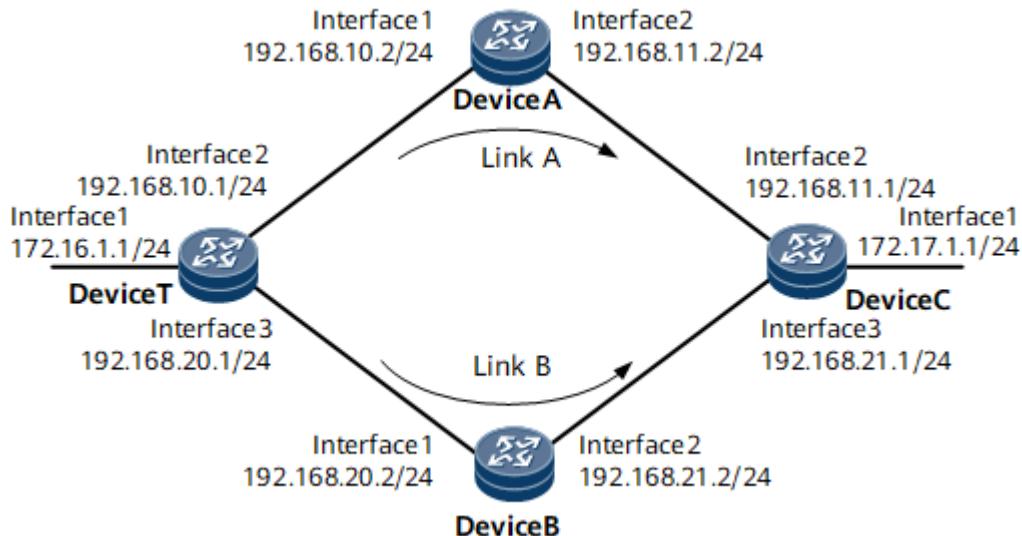

Networking Requirements

On the network shown in [Figure 1-29](#), it is required that the backup outbound interface and backup next hop be configured on Device T to ensure that Link B functions as a backup of Link A. If Link A fails, traffic is rapidly switched to the backup link (Link B).

Figure 1-29 Networking for configuring public network IPv4 FRR

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

Precautions

Before configuring public network IPv4 FRR, there must be at least two routes of different routing protocols but destined for the same IP address.

Configuration Roadmap

The configuration roadmap is as follows:

1. Enable basic OSPF functions on Device T, Device A, and Device C.
2. Configure basic IS-IS functions on Device T, Device B, and Device C.
3. Enable public network IPv4 FRR on Device T, and check the backup outbound interface and backup next hop.
4. Disable IPv4 FRR, and check the backup outbound interface and backup next hop.

Data Preparation

To complete the configuration, you need the following data:

- OSPF process IDs of Device T, Device A, and Device C
- IS-IS area addresses of Device T, Device B, and Device C

Procedure

- Step 1** Configure an IP address for each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure OSPF on Device T, Device A, and Device C. For configuration details, see [Configuration Files](#) in this section.
- Step 3** Configure IS-IS on Device T, Device B, and Device C. For configuration details, see [Configuration Files](#) in this section.
- Step 4** Check routing information.

Check the routes to 172.17.1.0 on Device T.

```
<DeviceT> display ip routing-table 172.17.1.0 verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Summary Count : 2

Destination: 172.17.1.0/24
  Protocol: OSPF      Process ID: 1
  Preference: 10      Cost: 3
    NextHop: 192.168.10.2   Neighbour: 0.0.0.0
    State: Active Adv     Age: 00h00m07s
      Tag: 0            Priority: low
      Label: NULL        QoSInfo: 0xa98ac7
    IndirectID: 0x40000041
    RelayNextHop: 0.0.0.0   Interface: GigabitEthernet2/0/0
      TunnelID: 0x0          Flags: D
      RouteColor: 0

Destination: 172.17.1.0/24
  Protocol: ISIS       Process ID: 1
  Preference: 15      Cost: 30
    NextHop: 192.168.20.2   Neighbour: 0.0.0.0
    State: Inactive Adv    Age: 00h01m26s
      Tag: 0            Priority: high
      Label: NULL        QoSInfo: 0xa98ac7
    IndirectID: 0x80000081
    RelayNextHop: 0.0.0.0   Interface: GigabitEthernet3/0/0
      TunnelID: 0x0          Flags: 0
      RouteColor: 0
```

In the routing table, you can view that there are two routes to 172.17.1.0/24. The route with 192.168.10.2 as the next hop is optimal because the OSPF route priority is higher than the IS-IS route priority.

- Step 5** Enable public network IPv4 FRR.

Enable IPv4 FRR on Device T.

```
[~DeviceT] ip frr
[*DeviceT] commit
```

Check the backup outbound interface and backup next hop on Device T.

```
<DeviceT> display ip routing-table 172.17.1.0 verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Summary Count : 2

Destination: 172.17.1.0/24
    Protocol: OSPF          Process ID: 1
    Preference: 10           Cost: 3
    NextHop: 192.168.10.2   Neighbour: 0.0.0.0
    State: Active Adv       Age: 00h01m36s
    Tag: 0                  Priority: low
    Label: NULL             QoSInfo: 0xa98ac7
    IndirectID: 0x400000041
    RelayNextHop: 0.0.0.0    Interface: GigabitEthernet2/0/0
    TunnelID: 0x0            Flags: D
    RouteColor: 0
    BkNextHop: 192.168.20.2 BkInterface: GigabitEthernet3/0/0
    BkLabel: NULL            SecTunnelID: 0x0
    BkPETunnelID: 0x0        BkPESecTunnelID: 0x0
    BkIndirectID: 0x800000081

Destination: 172.17.1.0/24
    Protocol: ISIS          Process ID: 1
    Preference: 15           Cost: 30
    NextHop: 192.168.20.2   Neighbour: 0.0.0.0
    State: Inactive Adv      Age: 00h02m55s
    Tag: 0                  Priority: high
    Label: NULL             QoSInfo: 0xa98ac7
    IndirectID: 0x800000081
    RelayNextHop: 0.0.0.0    Interface: GigabitEthernet3/0/0
    TunnelID: 0x0            Flags: 0
    RouteColor: 0
```

The routing table shows that the route to 172.17.1.0/24 has the backup outbound interface and backup next hop and that the IS-IS route is the backup route.

Step 6 Verify the configuration.

Simulate a link fault on Device T.

```
[~DeviceT] interface gigabitethernet 2/0/0
[~DeviceT-GigabitEthernet2/0/0] shutdown
[*DeviceT-GigabitEthernet2/0/0] commit
[~DeviceT-GigabitEthernet2/0/0] quit
```

Check the routes to 172.17.1.0/24 on Device T.

```
<DeviceT> display ip routing-table 172.17.1.0 verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Summary Count : 1

Destination: 172.17.1.0/24
    Protocol: ISIS          Process ID: 1
    Preference: 15           Cost: 30
    NextHop: 192.168.20.2   Neighbour: 0.0.0.0
    State: Active Adv       Age: 00h57m30s
    Tag: 0                  Priority: high
    Label: NULL             QoSInfo: 0xa98ac7
    IndirectID: 0x800000081
    RelayNextHop: 0.0.0.0    Interface: GigabitEthernet3/0/0
    TunnelID: 0x0            Flags: D
    RouteColor: 0
```

The preceding command output shows that traffic is switched to Link B after Link A fails.

----End

Example for Configuring Public Network IPv6 FRR

With public network IPv6 FRR, traffic can be rapidly switched to a backup link if the primary link fails.

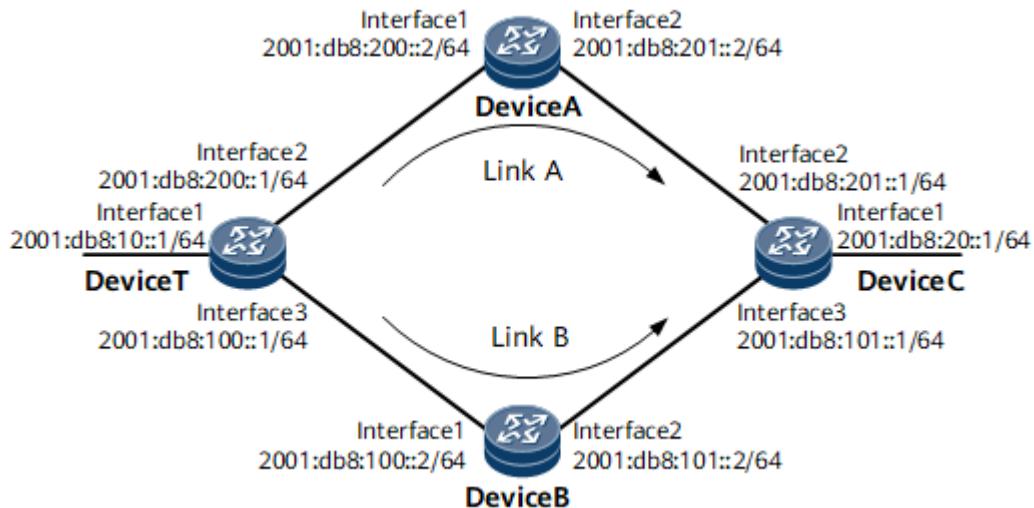

Networking Requirements

On the network shown in [Figure 1-30](#), it is required that the backup outbound interface and backup next hop must be configured on Device T so that link B functions as the backup of link A. If link A fails, traffic is rapidly switched to the backup link (Link B).

Figure 1-30 Networking for configuring public network IPv6 FRR

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

Precautions

Before configuring public network IPv6 FRR, there must be at least two routes of different routing protocols but destined for the same IPv6 address.

Configuration Roadmap

The configuration roadmap is as follows:

1. Enable OSPFv3 on Device T, Device A, and Device C.
2. Enable IPv6 IS-IS on Device T, Device B, and Device C.
3. Enable public network IPv6 FRR on Device T, and then check information about the backup outbound interface and backup next hop.
4. Disable IPv6 FRR, and then check information about the backup outbound interface and backup next hop.

Data Preparation

To complete the configuration, you need the following data:

- OSPFv3 process IDs of Device T, Device A, and Device C (OSPFv3 process ID is 1)
- IPv6 IS-IS area addresses of Device T, Device B, and Device C

Procedure

- Step 1** Configure an IPv6 address for each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure OSPFv3 on Device T, Device A, and Device C. For configuration details, see [Configuration Files](#) in this section.
- Step 3** Configure IPv6 IS-IS on Device T, Device B, and Device C. For configuration details, see [Configuration Files](#) in this section.

Step 4 Check routing information.

On Device T, check the routes to 2001:db8:20::1.

```
<DeviceT> display ipv6 routing-table 2001:db8:20::1 64 verbose
Routing Table : _public_
Summary Count : 2

Destination : 2001:db8:20:: PrefixLength : 64
NextHop   : 2001:db8:200::2 Preference  : 10
Neighbour  : :: ProcessID   : 1
Label      : NULL Protocol    : OSPFv3
State      : Active Adv Cost        : 3
Entry ID   : 0 EntryFlags   : 0x00000000
Reference Cnt: 0 Tag          : 0
IndirectID : 0x69 Age          : 269sec
RelayNextHop : :: TunnelID    : 0x0
Interface   : gigabitethernet 2/0/0 Flags        : D

Destination : 2001:db8:20:: PrefixLength : 64
NextHop   : 2001:db8:100::2 Preference  : 15
Neighbour  : :: ProcessID   : 1
Label      : NULL Protocol    : ISIS
State      : Inactive Adv Cost        : 30
Entry ID   : 0 EntryFlags   : 0x00000000
Reference Cnt: 0 Tag          : 0
IndirectID : 0xb5 Age          : 201sec
RelayNextHop : :: TunnelID    : 0x0
Interface   : gigabitethernet 3/0/0 Flags        : 0
```

The preceding command output shows that there are two routes to 2001:db8:20::1/64 and that the route with 2001:db8:200::2 as the next hop is optimal because the OSPFv3 route priority is higher than the IPv6 IS-IS route priority.

Step 5 Enable public network IPv6 FRR.

Enable IPv6 FRR on Device T.

```
[~DeviceT] ipv6 frr
[*DeviceT] commit
```

Check information about the backup outbound interface and backup next hop on Device T.

```
<DeviceT> display ipv6 routing-table 2001:db8:20::1 64 verbose
Routing Table : _public_
Summary Count : 2

Destination : 2001:db8:20:: PrefixLength : 64
NextHop   : 2001:db8:200::2 Preference  : 10
Neighbour  : :: ProcessID   : 1
Label      : NULL Protocol    : OSPFv3
State      : Active Adv Cost        : 3
Entry ID   : 0 EntryFlags   : 0x00000000
Reference Cnt: 0 Tag          : 0
IndirectID : 0x69 Age          : 553sec
RelayNextHop : :: TunnelID    : 0x0
Interface   : gigabitethernet 2/0/0 Flags        : D
BkNextHop  : 2001:db8:100::2 BkInterface  : gigabitethernet 3/0/0
BkLabel    : NULL BkTunnelID  : 0x0
BkPETunnelID: 0xb5 BkIndirectID : 0xb5

Destination : 2001:db8:20:: PrefixLength : 64
NextHop   : 2001:db8:100::2 Preference  : 15
Neighbour  : :: ProcessID   : 1
Label      : NULL Protocol    : ISIS
State      : Inactive Adv Cost        : 30
```

Entry ID : 0	EntryFlags : 0x00000000
Reference Cnt: 0	Tag : 0
IndirectID : 0xb5	Age : 485sec
RelayNextHop ::	TunnelID : 0x0
Interface : gigabitethernet 3/0/0	Flags : 0

The preceding command output shows that the route to 2001:db8:20::1/64 has a backup outbound interface and a backup next hop and that the IPv6 IS-IS route is the backup route.

Step 6 Verify the configuration.

Simulate a link fault on Device T.

```
[~DeviceT] interface gigabitethernet 2/0/0
[~DeviceT-GigabitEthernet2/0/0] shutdown
[*DeviceT-GigabitEthernet2/0/0] commit
[~DeviceT-GigabitEthernet2/0/0] quit
```

On Device T, check the routes to 2001:db8:20::1/64.

```
<DeviceT> display ipv6 routing-table 2001:db8:20::1 64 verbose
Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:20::          PrefixLength : 64
NextHop    : 2001:db8:100:2        Preference   : 15
Neighbour   ::                      ProcessID   : 1
Label      : NULL                  Protocol    : ISIS
State       : Active Adv          Cost        : 30
Entry ID   : 0                     EntryFlags  : 0x00000000
Reference Cnt: 0                  Tag         : 0
IndirectID : 0xb5                Age         : 1279sec
RelayNextHop ::                   TunnelID   : 0x0
Interface   : gigabitethernet 3/0/0 Flags       : D
```

The preceding command output shows that traffic has been switched to link B.

Example for Associating Direct Routes with a VRRP Group

Associating direct routes with a Virtual Router Redundancy Protocol (VRRP) group prevents user-to-network traffic and network-to-user traffic that traverse the VRRP group from being transmitted on different paths.

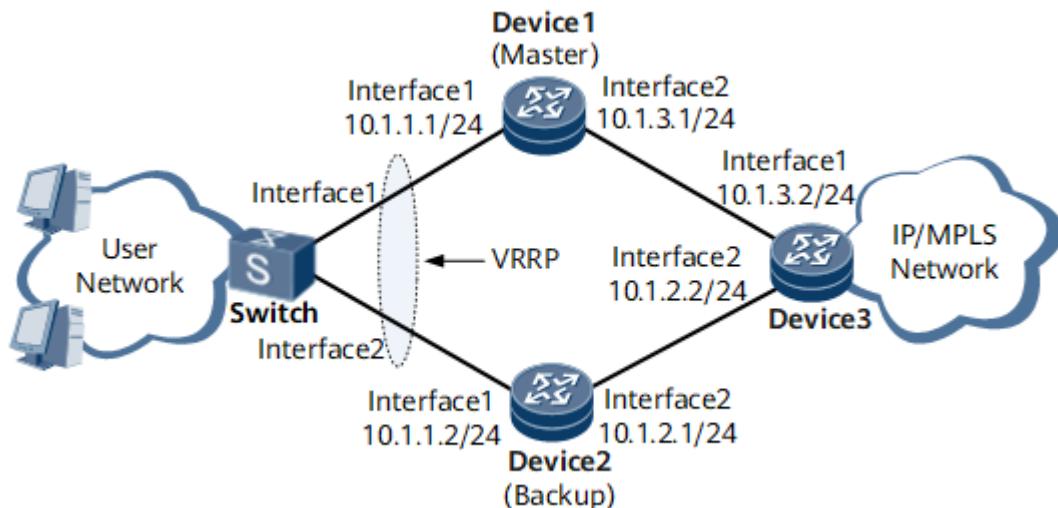

Networking Requirements

On the network shown in [Figure 1-31](#), the VRRP group consisting of Device1 and Device2 functions as the user-side gateway. User-to-network traffic is forwarded through the master device (Device1) of the VRRP group. In addition, the Open Shortest Path First (OSPF) protocol runs on Device 1, Device 2, and Device 3 so that these devices can communicate with one another at the IP layer. Network-to-user traffic travels on the path that OSPF selects. Device 3 has two equal-cost routes destined for the user network segment 10.1.1.0/24 that OSPF selects. Therefore, the two routes load-balance the network-to-user traffic. User-to-network traffic and network-to-user traffic travel on different paths.

Figure 1-31 Association between direct routes and a VRRP group

 **NOTE**

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 1/0/1, respectively.

To resolve this problem, associate direct routes with the VRRP group on VRRP-enabled interfaces of Device1 and Device2 to increase the cost of the direct route to the virtual IP network segment of the VRRP group, import the direct route to OSPF, and configure OSPF to inherit the costs of the imported external routes. Because the cost of the OSPF route passing through Device1 is smaller, Device3 preferentially selects this route to forward downstream traffic. In this manner, upstream and downstream traffic is transmitted along the same path.

Precautions

During the configuration, pay attention to the following points:

- OSPF cannot run on Device 1's and Device 2's VRRP-enabled interfaces. If both VRRP and OSPF run on Device 1's and Device 2's interfaces, OSPF cannot inherit the costs from the imported direct routes after the association.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure a VRRP group on Device 1 and Device 2.
2. Configure OSPF on Device 1, Device 2, and Device 3.
3. Associate direct routes with the VRRP group on Device 1 and Device 2.
4. Enable OSPF to import direct routes on Device 1 and Device 2 and to inherit the costs of the imported direct routes.

Data Preparation

To complete the configuration, you need the following data:

- VLAN ID 10 configured on the Switch
- VRRP ID 1 and a virtual IP address 10.1.1.111 of the VRRP group
- Device 1's VRRP priority 120
- Cost of direct routes to the virtual IP network segment on Device 2 (300)

Procedure

Step 1 Configure an IP address for each interface. For configuration details, see [Configuration File](#) in this section.

Step 2 Configure a VRRP group.

```
# Configure a VLAN with VLAN ID 10 on the Switch. Add GE 1/0/0 and GE 1/0/1 to VLAN 10 so that the Switch transparently transmits VRRP packets sent by Device 1 or Device 2.
```

```
<Switch> system-view
[~Switch] interface gigabitethernet 1/0/0
[~Switch-GigabitEthernet1/0/0] portswitch
[*Switch-GigabitEthernet1/0/0] commit
[*Switch-GigabitEthernet1/0/0] quit
[*Switch] interface gigabitethernet 1/0/1
[~Switch-GigabitEthernet1/0/1] portswitch
[*Switch-GigabitEthernet1/0/1] commit
[~Switch-GigabitEthernet1/0/1] quit
[*Switch] vlan 10
[*Switch-vlan10] port gigabitethernet 1/0/0
[*Switch-vlan10] port gigabitethernet 1/0/1
[*Switch-vlan10] commit
[~Switch-vlan10] quit
```

```
# Create VRRP group 1 on Device 1, and set the priority of Device 1 in the VRRP group to 120 so that Device 1 functions as the master device.
```

```
<Device1> system-view
[~Device1] interface gigabitethernet 1/0/0
[*Device1-GigabitEthernet1/0/0] vrrp vrid 1 virtual-ip 10.1.1.111
[*Device1-GigabitEthernet1/0/0] vrrp vrid 1 priority 120
[*Device1-GigabitEthernet1/0/0] commit
[~Device1-GigabitEthernet1/0/0] quit
```

```
# Create VRRP group 1 on Device 2
```

```
<Device2> system-view
[~Device2] interface gigabitethernet 1/0/0
[*Device2-GigabitEthernet1/0/0] vrrp vrid 1 virtual-ip 10.1.1.111
[*Device2-GigabitEthernet1/0/0] commit
[~Device2-GigabitEthernet1/0/0] quit
```

Step 3 Configure OSPF.

```
# Configure OSPF on Device 1.
```

```
[~Device1] ospf 1
[*Device1-ospf-1] area 0
[*Device1-ospf-1-area-0.0.0.0] network 10.1.3.0 0.0.0.255
[*Device1-ospf-1-area-0.0.0.0] commit
[~Device1-ospf-1-area-0.0.0.0] quit
[~Device1-ospf-1] quit
```

```
# Configure OSPF on Device 2.
```

```
[~Device2] ospf 1
[*Device2-ospf-1] area 0
[*Device2-ospf-1-area-0.0.0.0] network 10.1.2.0 0.0.0.255
[*Device2-ospf-1-area-0.0.0.0] commit
[~Device2-ospf-1-area-0.0.0.0] quit
[~Device2-ospf-1] quit
```

```
# Configure OSPF on Device 3.
```

```
<Device3> system-view
[~Device3] ospf 1
```

```
[*Device3-ospf-1] area 0
[*Device3-ospf-1-area-0.0.0] network 10.1.2.0 0.0.0.255
[*Device3-ospf-1-area-0.0.0] network 10.1.3.0 0.0.0.255
[*Device3-ospf-1-area-0.0.0] commit
[~Device3-ospf-1-area-0.0.0] quit
[~Device3-ospf-1] quit
```

Step 4 Associate direct routes with the VRRP group.

Configure Device1.

```
[~Device1] interface gigabitethernet 1/0/0
[*Device1-GigabitEthernet1/0/0] direct-route track vrrp vrid 1 degrade-cost 300
[*Device1-GigabitEthernet1/0/0] commit
[~Device1-GigabitEthernet1/0/0] quit
```

Configure Device2.

```
[~Device2] interface gigabitethernet 1/0/0
[*Device2-GigabitEthernet1/0/0] direct-route track vrrp vrid 1 degrade-cost 300
[*Device2-GigabitEthernet1/0/0] commit
[~Device2-GigabitEthernet1/0/0] quit
```

Step 5 Configure OSPF to import direct routes.

Configure OSPF on Device 1.

```
[~Device1] ospf 1
[*Device1-ospf-1] import-route direct
[*Device1-ospf-1] default cost inherit-metric
[*Device1-ospf-1] commit
[~Device1-ospf-1] quit
```

Configure OSPF on Device 2.

```
[~Device2] ospf 1
[*Device2-ospf-1] import-route direct
[*Device2-ospf-1] default cost inherit-metric
[*Device2-ospf-1] commit
[~Device2-ospf-1] quit
```

Step 6 Check the configuration.

Run the **display ip routing-table** command on Device2 to view information about the IP routing table. The command output shows that the cost of the direct route to the VRRP virtual IP network segment is 300.

```
<Device2> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Destinations : 12      Routes : 12
Destination/Mask Proto Pre Cost     Flags NextHop       Interface
10.1.1.0/24 Direct 0   300        D 10.1.1.2      GigabitEthernet1/0/0
10.1.1.2/32 Direct 0   0          D 127.0.0.1    GigabitEthernet1/0/0
10.1.1.111/32 O_ASE 150 0        D 10.1.2.2      GigabitEthernet1/0/1
10.1.1.255/32 Direct 0   0          D 127.0.0.1    GigabitEthernet1/0/0
10.1.2.0/24 Direct 0   0          D 10.1.2.1      GigabitEthernet1/0/1
10.1.2.1/32 Direct 0   0          D 127.0.0.1    GigabitEthernet1/0/1
10.1.2.255/32 Direct 0   0          D 127.0.0.1    GigabitEthernet1/0/1
10.1.3.0/24 OSPF   10  2          D 10.1.2.2      GigabitEthernet1/0/1
127.0.0.0/8 Direct 0   0          D 127.0.0.1    InLoopBack0
127.0.0.1/32 Direct 0   0          D 127.0.0.1    InLoopBack0
127.255.255.255/32 Direct 0   0          D 127.0.0.1    InLoopBack0
255.255.255.255/32 Direct 0   0          D 127.0.0.1    InLoopBack0
```

Run the **display ip routing-table 10.1.1.0** command on Device3 to view information about the route destined for the network segment. The command

output shows that Device3 selects the route with next-hop address 10.1.3.1 (passing through VRRP master device Device1) for downstream traffic to the user.

```
<Device3> display ip routing-table 10.1.1.0
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
```

```
Routing Table : _public_
Summary Count : 1
```

Example for Importing IPv4 ARP Vlink Direct Routes to BGP

By importing IPv4 ARP Vlink direct routes to BGP, you can enable the remote device to obtain information about detailed routes in the VLAN, allowing precise control of data traffic.

Networking Requirements

As networks develop, the VLAN technology is widely used. If a user outside a VLAN needs to communicate with users within the VLAN, advertising routes destined for the network segment of the VLAN can achieve this purpose. When users outside the VLAN need to know the IPv4 ARP Vlink direct routes of the VLAN, and apply different traffic policies to routes of the VLAN users, advertising the routes destined for the network segment of the VLAN cannot meet this requirement.

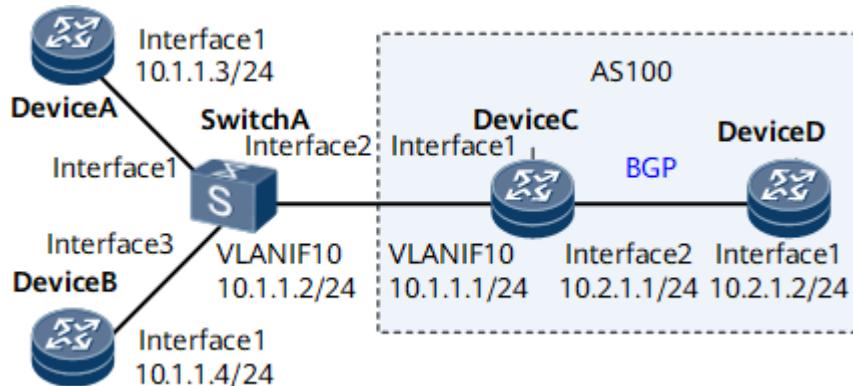

In this case, you can enable the function of IPv4 ARP Vlink direct route advertisement. As shown in [Figure 1-32](#), Device C is connected to two VLAN sites through VLANIF interfaces. Device D communicates with Device B, but not with Device A. To meet the communication requirement, you can enable the function of IPv4 ARP Vlink direct route advertisement on Device C, and use a route-policy to filter out the routes to the network segment of the VLAN and the route to Device A.

Figure 1-32 Networking diagram of importing IPv4 ARP Vlink direct routes to BGP

NOTE

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

Configuration Roadmap

The configuration roadmap is as follows:

1. Create VLANIF interfaces on Switch A and Device C and assign IP addresses to the VLANIF interfaces, and ensure that Device A, Device B, Switch A, and Device C can communicate with each other.
2. Enable BGP on Device C and Device D, ensuring that Device C and Device D are able to advertise IP routes to each other.
3. Enable the function of IPv4 ARP Vlink direct route advertisement on Device C.
4. Configure a route-policy on Device C, allowing routes only from Device B to pass through.
5. Enable BGP on Device C to import direct routes, and use the route-policy to import routes only from Device B.
6. Associate BGP with the route-policy on Device C to filter out the network segment route of the VLAN so that Device D cannot learn the network segment route and can communicate with VLAN users based only on IPv4 ARP Vlink direct routes.

Data Preparation

To complete the configuration, you need the following data:

- ID of the VLAN in which Switch A and Device C reside (the VLAN ID is 10 in this example)
- Router IDs and AS numbers of Devices C and D (router ID of Device C is 3.3.3.3 and router ID of Device D is 4.4.4.4, and Devices C and D are in AS 100 in this example)
- Route-policy used to filter direct routes (the route-policy is policy1 in this example)
- Route-policy used to advertise BGP routes on Device C (the route-policy is policy2 in this example)

Procedure

Step 1 Configure an IP address for each interface.

Configure Device A.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceA
[*HUAWEI] commit
[~DeviceA] interface GigabitEthernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] undo shutdown
[*DeviceA-GigabitEthernet1/0/0] ip address 10.1.1.3 24
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
```

Configure Device B.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceB
[*HUAWEI] commit
[~DeviceB] interface GigabitEthernet 1/0/0
[*DeviceB-GigabitEthernet1/0/0] undo shutdown
[*DeviceB-GigabitEthernet1/0/0] ip address 10.1.1.4 24
[*DeviceB-GigabitEthernet1/0/0] commit
[~DeviceB-GigabitEthernet1/0/0] quit
```

Configure Device C.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceC
[*HUAWEI] commit
[~DeviceC] interface GigabitEthernet 2/0/0
[*DeviceC-GigabitEthernet2/0/0] undo shutdown
[*DeviceC-GigabitEthernet2/0/0] ip address 10.2.1.1 24
[*DeviceC-GigabitEthernet2/0/0] commit
[~DeviceC-GigabitEthernet2/0/0] quit
```

Configure Device D.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceD
[*HUAWEI] commit
[~DeviceD] interface GigabitEthernet 1/0/0
[*DeviceD-GigabitEthernet1/0/0] undo shutdown
[*DeviceD-GigabitEthernet1/0/0] ip address 10.2.1.2 24
[*DeviceD-GigabitEthernet1/0/0] commit
[~DeviceD-GigabitEthernet1/0/0] quit
```

Step 2 Configure basic VLAN functions. Create VLANIF 10 on Switch A and Device C and assign IP addresses to the VLANIF interfaces.

Configure Switch A.

```
<HUAWEI> system-view
[~HUAWEI] sysname SwitchA
[*HUAWEI] commit
[~SwitchA] vlan 10
[*SwitchA-vlan10] quit
[*SwitchA] interface GigabitEthernet 1/0/0
[*SwitchA-GigabitEthernet1/0/0] portswitch
[*SwitchA-GigabitEthernet1/0/0] undo shutdown
[*SwitchA-GigabitEthernet1/0/0] port link-type access
[*SwitchA-GigabitEthernet1/0/0] port default vlan 10
[*SwitchA-GigabitEthernet1/0/0] quit
[*SwitchA] interface GigabitEthernet 2/0/0
[*SwitchA-GigabitEthernet2/0/0] portswitch
[*SwitchA-GigabitEthernet2/0/0] undo shutdown
[*SwitchA-GigabitEthernet2/0/0] port link-type access
[*SwitchA-GigabitEthernet2/0/0] port default vlan 10
```

```
[*SwitchA-GigabitEthernet2/0/0] quit
[*SwitchA] interface GigabitEthernet 3/0/0
[*SwitchA-GigabitEthernet3/0/0] portswitch
[*SwitchA-GigabitEthernet3/0/0] undo shutdown
[*SwitchA-GigabitEthernet3/0/0] port link-type access
[*SwitchA-GigabitEthernet3/0/0] port default vlan 10
[*SwitchA-GigabitEthernet3/0/0] quit
[*SwitchA] interface Vlanif 10
[*SwitchA-Vlanif10] ip address 10.1.1.2 24
[*SwitchA-Vlanif10] commit
[~SwitchA-Vlanif10] quit
```

Configure Device C.

```
[~DeviceC] vlan 10
[~DeviceC-vlan10] quit
[*DeviceC] interface GigabitEthernet 1/0/0
[*DeviceC-GigabitEthernet1/0/0] portswitch
[*DeviceC-GigabitEthernet1/0/0] undo shutdown
[*DeviceC-GigabitEthernet1/0/0] port link-type access
[*DeviceC-GigabitEthernet1/0/0] port default vlan 10
[*DeviceC-GigabitEthernet1/0/0] quit
[*DeviceC] interface Vlanif 10
[*DeviceC-Vlanif10] ip address 10.1.1.1 24
[*DeviceC-Vlanif10] commit
[~DeviceC-Vlanif10] quit
```

Step 3 Configure BGP between Device C and Device D.

Configure Device C.

```
[~DeviceC] bgp 100
[*DeviceC-bgp] router-id 3.3.3.3
[*DeviceC-bgp] peer 10.2.1.2 as-number 100
[*DeviceC-bgp] commit
[~DeviceC-bgp] quit
```

Configure Device D.

```
[~DeviceD] bgp 100
[*DeviceD-bgp] router-id 4.4.4.4
[*DeviceD-bgp] peer 10.2.1.1 as-number 100
[*DeviceD-bgp] commit
[~DeviceD-bgp] quit
```

Step 4 Configure BGP on Device C and import direct routes to BGP. Then view the routing tables of Devices C and D.

Configure Device C.

```
[~DeviceC] bgp 100
[~DeviceC-bgp] import-route direct
[*DeviceC-bgp] commit
[~DeviceC-bgp] quit
```

Display the BGP routing table of Device C.

```
[~DeviceC] display bgp routing-table
BGP Local router ID is 3.3.3.3
Status codes: * - valid, > - best, d - damped, x - best external, a - add path,
              h - history, i - internal, s - suppressed, S - Stale
              Origin : i - IGP, e - EGP, ? - incomplete
              RPKI validation codes: V - valid, I - invalid, N - not-found

Total Number of Routes: 9

```

You can see that Device D has not learned the two IPv4 ARP Vlink direct routes 10.1.1.3/32 and 10.1.1.4/32.

Step 5 Enable the function of IPv4 ARP Vlink direct route advertisement on Device C and configure the route-policy **policy1** to filter out the routes to the network segment of the VLAN and the IPv4 ARP Vlink direct route from Device A, 10.1.1.3/32.

Configure Device C.

```
[~DeviceC] ip ip-prefix prefix1 permit 10.1.1.4 32
[*DeviceC] route-policy policy1 permit node 10
[*DeviceC-route-policy] if-match ip-prefix prefix1
[*DeviceC-route-policy] quit
[*DeviceC] arp vlink-direct-route advertise route-policy policy1
[*DeviceC] commit
```

Display the BGP routing table of Device C.

```
[~DeviceC] display bgp routing-table
BGP Local router ID is 3.3.3.3
Status codes: * - valid, > - best, d - damped, x - best external, a - add path,
              h - history, i - internal, s - suppressed, S - Stale
              Origin : i - IGP, e - EGP, ? - incomplete
              RPKI validation codes: V - valid, I - invalid, N - not-found

Total Number of Routes: 9
Network          NextHop        MED     LocPrf  PrefVal Path/Ogn

```

Display the BGP routing table of Device D.

```
[~DeviceD] display bgp routing-table
BGP Local router ID is 4.4.4.4
Status codes: * - valid, > - best, d - damped, x - best external, a - add path,
              h - history, i - internal, s - suppressed, S - Stale
              Origin : i - IGP, e - EGP, ? - incomplete
              RPKI validation codes: V - valid, I - invalid, N - not-found

Total Number of Routes: 3
```

Network	NextHop	MED	LocPrf	PrefVal	Path/Ogn
*>i 10.1.1.0/24	10.2.1.1	0	100	0	?
*>i 10.1.1.4/32	10.2.1.1	0	100	0	?
i 10.2.1.0/24	10.2.1.1	0	100	0	?

You can see that Device D has learned the IPv4 ARP Vlink direct route 10.1.1.4/32, whereas the route 10.1.1.3/32 has been filtered out.

- Step 6** Use the route-policy **policy2** to filter out the network segment route 10.1.1.0/24 on Device C when BGP routes are advertised.

Configure Device C.

```
[~DeviceC] ip ip-prefix prefix2 index 10 deny 10.1.1.0 24
[*DeviceC] ip ip-prefix prefix2 index 20 permit 0.0.0.0 0 less-equal 32
[*DeviceC] route-policy policy2 permit node 10
[*DeviceC-route-policy] if-match ip-prefix prefix2
[*DeviceC-route-policy] quit
[*DeviceC] bgp 100
[*DeviceC-bgp] peer 10.2.1.2 route-policy policy2 export
[*DeviceC-bgp] commit
[~DeviceC-bgp] quit
[~DeviceC] quit
<DeviceC> refresh bgp all export
```

Display the BGP routing table of Device D.

```
[~DeviceD] display bgp routing-table
BGP Local router ID is 4.4.4.4
Status codes: * - valid, > - best, d - damped, x - best external, a - add path,
              h - history, i - internal, s - suppressed, S - Stale
              Origin : i - IGP, e - EGP, ? - incomplete
RPKI validation codes: V - valid, I - invalid, N - not-found

Total Number of Routes: 2
Network          NextHop        MED     LocPrf    PrefVal Path/Ogn
*>i 10.1.1.4/32  10.2.1.1      0       100      0       ?
i 10.2.1.0/24   10.2.1.1      0       100      0       ?
```

You can find that the route 10.1.1.0/24 does not exist in the BGP routing table of Device D. As a result, Device D can communicate with Device B, but cannot communicate with Device A.

Example for Importing IPv6 NDP Vlink Direct Routes to BGP4+

By importing IPv6 NDP Vlink direct routes to BGP4+, you can enable the remote device to obtain information about detailed routes in the VLAN, allowing precise control of data traffic.

Networking Requirements

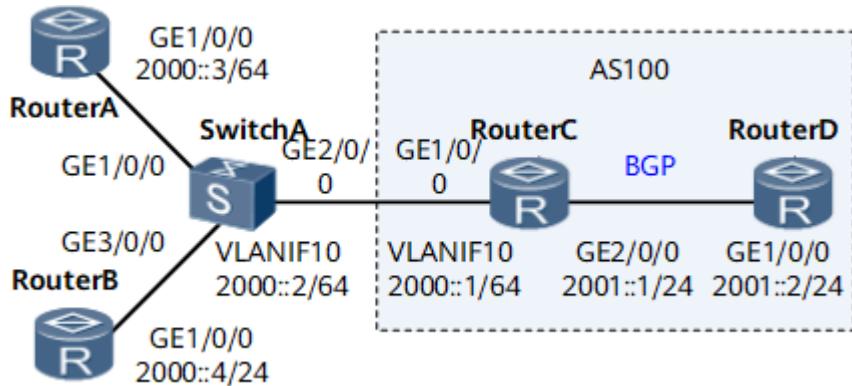

As networks develop, the VLAN technology is widely used. If a user outside a VLAN needs to communicate with users within the VLAN, advertising routes destined for the network segment of the VLAN can achieve this purpose. When users outside the VLAN need to know the IPv6 NDP Vlink direct routes of the VLAN, and apply different traffic policies to routes of the VLAN users, advertising the routes destined for the network segment of the VLAN cannot meet this requirement.

In this case, you can enable the function of IPv6 NDP Vlink direct route advertisement. On the network shown in [Figure 1-33](#), DeviceC is connected to two users through VLANIF interfaces. DeviceD needs to communicate with DeviceB, but not with DeviceA. In this case, you can enable the function of IPv6 NDP Vlink direct route advertisement on DeviceC, and use a route-policy to filter out subnet routes and the route to DeviceA.

Figure 1-33 Networking diagram of importing IPv6 NDP Vlink direct routes to BGP4+

NOTE

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

Configuration Roadmap

The configuration roadmap is as follows:

1. Create VLANIF interfaces on SwitchA and DeviceC and assign IPv6 addresses to the VLANIF interfaces, and ensure that DeviceA, DeviceB, SwitchA, and DeviceC can communicate with each other.
2. Enable BGP4+ on DeviceC and DeviceD, ensuring that DeviceC and DeviceD are able to advertise IPv6 routes to each other.
3. Enable the function of IPv6 NDP Vlink direct route advertisement on DeviceC.
4. Configure a route-policy on DeviceC, allowing IPv6 routes only from DeviceB to pass through.
5. Enable BGP4+ on DeviceC and import IPv6 direct routes to BGP4+, and use the route-policy to import IPv6 routes only from DeviceB to BGP4+.
6. Associate BGP4+ with the route-policy on DeviceC to filter out the network segment route of the VLAN so that DeviceD cannot learn the network segment route and can communicate with VLAN users based only on IPv6 NDP Vlink direct routes.

Data Preparation

To complete the configuration, you need the following data:

- ID of the VLAN in which SwitchA and DeviceC reside (the VLAN ID is 10 in this example)
- Router IDs and AS numbers of Devices C and D (router ID of DeviceC is 1.1.1.1 and router ID of DeviceD is 2.2.2.2, and Devices C and D are in AS 100 in this example)
- Route-policy used to filter direct routes (the route-policy is policy1 in this example)
- Route-policy used to advertise BGP4+ routes on DeviceC (the route-policy is policy2 in this example)

Procedure

Step 1 Configure an IP address for each interface.

Configure DeviceA.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceA
[*HUAWEI] commit
[~DeviceA] interface GigabitEthernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] ipv6 enable
[*DeviceA-GigabitEthernet1/0/0] ipv6 address 2001:db8:2000::3 64
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
```

Configure DeviceB.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceB
[*HUAWEI] commit
[*DeviceB] interface GigabitEthernet 1/0/0
[*DeviceB-GigabitEthernet1/0/0] undo shutdown
[*DeviceB-GigabitEthernet1/0/0] ipv6 enable
[*DeviceB-GigabitEthernet1/0/0] ipv6 address 2001:db8:2000::4 64
[*DeviceB-GigabitEthernet1/0/0] commit
[~DeviceB-GigabitEthernet1/0/0] quit
```

Configure DeviceC.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceC
[*HUAWEI] commit
[~DeviceC] interface GigabitEthernet 2/0/0
[*DeviceC-GigabitEthernet2/0/0] ipv6 enable
[*DeviceC-GigabitEthernet2/0/0] ipv6 address 2001:db8:2001::1 64
[*DeviceC-GigabitEthernet2/0/0] commit
[~DeviceC-GigabitEthernet2/0/0] quit
```

Configure DeviceD.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceD
[*HUAWEI] commit
[~DeviceD] interface GigabitEthernet 1/0/0
[*DeviceD-GigabitEthernet1/0/0] ipv6 enable
[*DeviceD-GigabitEthernet1/0/0] ipv6 address 2001:db8:2001::2 64
[*DeviceD-GigabitEthernet1/0/0] commit
[~DeviceD-GigabitEthernet1/0/0] quit
```

Step 2 Configure basic VLAN functions. Create VLANIF 10 on SwitchA and DeviceC and assign IP addresses to the VLANIF interfaces.

Configure SwitchA.

```
<HUAWEI> system-view
[~HUAWEI] sysname SwitchA
[*HUAWEI] commit
[~SwitchA] vlan 10
[*SwitchA-vlan10] quit
[*SwitchA] interface GigabitEthernet 1/0/0
[*SwitchA-GigabitEthernet1/0/0] portswitch
[*SwitchA-GigabitEthernet1/0/0] port link-type access
[*SwitchA-GigabitEthernet1/0/0] port default vlan 10
[*SwitchA-GigabitEthernet1/0/0] quit
[*SwitchA] interface GigabitEthernet 2/0/0
[*SwitchA-GigabitEthernet2/0/0] portswitch
[*SwitchA-GigabitEthernet2/0/0] port link-type access
[*SwitchA-GigabitEthernet2/0/0] port default vlan 10
[*SwitchA-GigabitEthernet2/0/0] quit
```

```
[*SwitchA] interface GigabitEthernet 3/0/0
[*SwitchA-GigabitEthernet3/0/0] portswitch
[*SwitchA-GigabitEthernet3/0/0] port link-type access
[*SwitchA-GigabitEthernet3/0/0] port default vlan 10
[*SwitchA-GigabitEthernet3/0/0] quit
[*SwitchA] interface Vlanif 10
[*SwitchA-Vlanif10] ipv6 enable
[*SwitchA-Vlanif10] ipv6 address 2001:db8:2000::2 64
[*SwitchA-Vlanif10] commit
[~SwitchA-Vlanif10] quit
```

Configure DeviceC.

```
[~DeviceC] vlan 10
[~DeviceC-vlan10] quit
[*DeviceC] interface GigabitEthernet 1/0/0
[*DeviceC-GigabitEthernet1/0/0] portswitch
[*DeviceC-GigabitEthernet1/0/0] port link-type access
[*DeviceC-GigabitEthernet1/0/0] port default vlan 10
[*DeviceC-GigabitEthernet1/0/0] quit
[*DeviceC] interface Vlanif 10
[*DeviceC-Vlanif10] ipv6 enable
[*DeviceC-Vlanif10] ipv6 address 2001:db8:2000::1 64
[*DeviceC-Vlanif10] commit
[~DeviceC-Vlanif10] quit
```

Step 3 Configure BGP4+ between DeviceC and DeviceD.

Configure DeviceC.

```
[~DeviceC] bgp 100
[*DeviceC-bgp] router-id 1.1.1.1
[*DeviceC-bgp] peer 2001:db8:2001::2 as-number 100
[*DeviceC-bgp] ipv6-family unicast
[*DeviceC-bgp-af-ipv6] peer 2001:db8:2001::2 enable
[*DeviceC-bgp-af-ipv6] commit
[~DeviceC-bgp-af-ipv6] quit
[~DeviceC-bgp] quit
```

Configure DeviceD.

```
[~DeviceD] bgp 100
[*DeviceD-bgp] router-id 2.2.2.2
[*DeviceD-bgp] peer 2001:db8:2001::1 as-number 100
[*DeviceD-bgp] ipv6-family unicast
[*DeviceD-bgp-af-ipv6] peer 2001:db8:2001::1 enable
[*DeviceD-bgp-af-ipv6] commit
[~DeviceD-bgp-af-ipv6] quit
[~DeviceD-bgp] quit
```

After the configuration is complete, run the **display bgp ipv6 peer** command to view status of BGP4+ peer relationships. The command output shows that the IBGP peer relationship has been established between DeviceC and DeviceD. Use the display on DeviceD as an example.

```
[~DeviceD] display bgp ipv6 peer
BGP local router ID : 2.2.2.2
Local AS number : 100
Total number of peers : 1          Peers in established state : 1
Peer      V      AS  MsgRcvd  MsgSent  OutQ  Up/Down    State PrefRcv
2001:db8:2001::1      4      100     64     59    0 00:52:15 Established    0
```

Step 4 Configure BGP4+ on DeviceC and import direct routes to BGP4+. Then view the routing tables of Devices C and D.

Configure DeviceC.

```
[~DeviceC] bgp 100
[*DeviceC-bgp] ipv6-family unicast
[*DeviceC-bgp-af-ipv6] import-route direct
[*DeviceC-bgp-af-ipv6] commit
[~DeviceC-bgp-af-ipv6] quit
[~DeviceC-bgp] quit
```

Display the BGP4+ routing table of DeviceC.

```
[~DeviceC] display bgp ipv6 routing-table
BGP Local router ID is 1.1.1.1

1.1.2 IPv4 Static Route Configuration

1.1.2.1 Static Routes Description

1.1.2.1.1 Overview of Static Routes

Definition

Static routes are special routes that are configured by network administrators.

Purpose

On a simple network, only static routes can ensure that the network runs properly. If a router cannot run dynamic routing protocols or cannot generate routes to a destination network, you can configure static routes on the router.

Route selection can be controlled using static routes. Properly configuring and using static routes can improve network performance and guarantee the required bandwidth for important applications. When a network fault occurs or the network topology changes, however, static routes must be changed manually by the administrator.

1.1.2.1.2 Understanding Static Routes

Components

On the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X, you can run the **ip route-static** command to configure a static route, which consists of the following components:

- **Destination address and mask**
- **Outbound interface and next hop address**

Destination Address and Mask

The IPv4 destination address in a static route is expressed in dotted decimal notation, while a mask can be expressed either in dotted decimal or CIDR notation.

The IPv6 destination address in a static route is a 32-digit hexadecimal number, while a prefix is expressed in CIDR notation and ranges from 0 to 128.

Outbound Interface and Next Hop Address

When creating a static route, you can specify *interface-type interface-number*, *nexthop-address*, or both. In addition, you can configure the Next-Table function, that is, only a VPN instance name (public in the case of the public network) is specified as the next hop of a static route, and no outbound interface or next hop address is specified. You can configure the parameters as required.

Every route requires a next-hop address. Before sending a packet, a device needs to search its routing table for the route matching the destination address in the packet using the longest match rule. The link layer can find the corresponding link-layer address and then forward the packet only when a next-hop IP address is available.

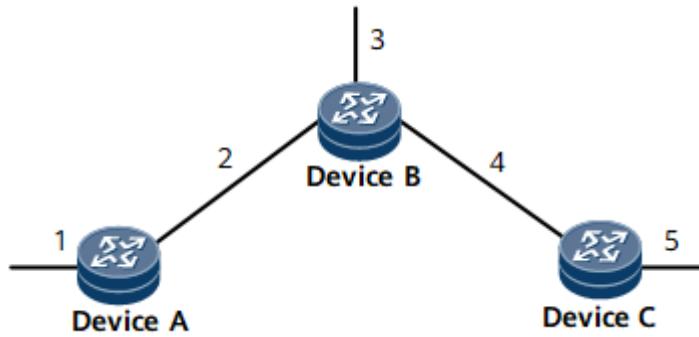

When specifying an outbound interface, note the following:

- For a Point-to-Point (P2P) interface, if an outbound interface is specified, the next hop address is the address of the remote interface connected to the outbound interface. For example, when a GE interface is configured with PPP encapsulation and obtains the remote IP address through PPP negotiation, you can specify only an outbound interface, without the need to specify a next hop address.
- Non-Broadcast Multiple-Access (NBMA) interfaces are applicable to Point-to-Multipoint networks. Therefore, IP routes and the mappings between IP addresses and link layer addresses are required. In this case, you need to configure next hop addresses.
- When configuring static routes, you are advised not to specify a broadcast interface (such as an Ethernet interface) or a virtual template (VT) interface as the outbound interface. Ethernet interfaces are broadcast interfaces, and each VT interface can be associated with multiple virtual access interfaces. If either of the two types of interfaces is specified as the outbound interface, multiple next hops exist and the next hop cannot be determined. In actual applications, to specify a broadcast interface (such as an Ethernet interface) or a VT interface as the outbound interface, you need to specify a next hop address along with the outbound interface.

Application Scenarios for Static Routes

In **Figure 1-34**, the network topology is simple, and network communication can be implemented through static routes. You need to specify an address for each physical network, identify indirectly connected physical networks for each device, and configure static routes for indirectly connected physical networks.

Figure 1-34 Networking for static routes

In this example, static routes to networks 3, 4, and 5 need to be configured on Device A; static routes to networks 1 and 5 need to be configured on Device B; static routes to networks 1, 2, and 3 need to be configured on Device C.

Default Static Route

Default routes are a special kind of routes, and default static routes are manually configured. The default route is used when no matched entry is available in the routing table. In an IPv4 routing table, the destination address and subnet mask of a default route are both 0.0.0.0. In an IPv6 routing table, the destination address and prefix of a default route are both ::.

If the destination address of a packet does not match any entry in the routing table, the device selects the default route to forward this packet. If no default route exists and the destination address of the packet does not match any entry in the routing table, the packet is discarded. An Internet Control Message Protocol (ICMP) packet is then sent, informing the originating host that the destination host or network is unreachable.

The static route with the destination address and mask 0s (0.0.0.0 0.0.0.0) configured using the **ip route-static** command is a default route intended to simplify network configuration.

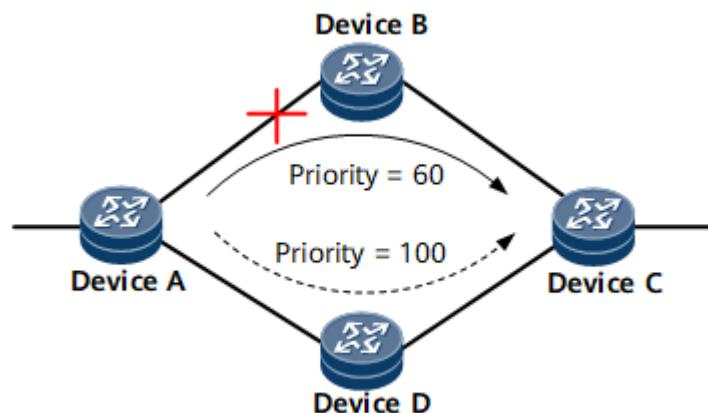

In [Figure 1-34](#), because the next hop of the packets from Device A to networks 3, 4, and 5 is Device B, a default route can be configured on Device A to replace the three static routes destined for networks 3, 4, and 5. Similarly, only a default route from Device C to Device B needs to be configured to replace the three static routes destined for networks 1, 2, and 3.

Floating Static Routes

Different static routes can be configured with different priorities so that routing management policies can be flexibly applied. Route backup can be implemented by specifying different priorities for multiple routes to the same destination.

In **Figure 1-35**, there are two static routes from Device A to Device C. In most cases, the only Active route is the static route with Device B as the next hop in the routing table because it has a higher priority. The other static route with Device D as the next hop functions as a backup route. The backup route is only activated to forward traffic if the primary link fails. After the primary link recovers, the static route with Device B as the next hop becomes Active to take over the traffic. Therefore, the backup route is also called a floating static route. The floating static route becomes ineffective if a fault occurs on the link between Device B and Device C.

Figure 1-35 Networking for a floating static route

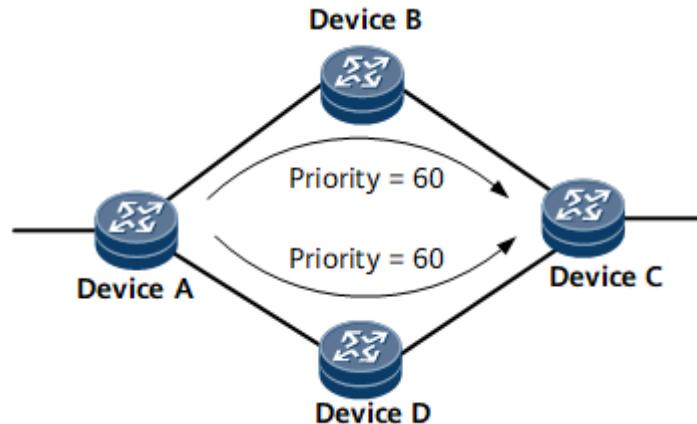

Load Balancing Among Static Routes

Routes to the same destination with the same priority can be used to load-balance traffic.

As shown in **Figure 1-36**, there are two static routes with the same priority from Device A to Device C. The two routes both exist in the routing table and forward traffic at the same time.

Figure 1-36 Load balancing among static routes

FRR for Static Routes

When routes are delivered to the routing management (RM) module, the optimal route is delivered with a backup route. If the optimal route fails, traffic is immediately switched to the backup route, minimizing traffic loss.

You need to configure two routes with the same prefix but different priorities to implement FRR. The route with the higher priority is the primary route, and the route with the lower priority is the backup route. FRR is implemented only on static routes that are manually configured. That is, FRR is not implemented on recursive next hops.

Functions

IPv4 Static Routes

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports common static routes and the static routes associated with VPN instances. The static routes associated with VPN instances are used to manage VPN routes. For details about VPN instances, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Feature Description - VPN*.

Attributes and Functions of IPv6 Static Routes

Similar to IPv4 static routes, IPv6 static routes are configured by the administrator and are applicable to simple IPv6 networks.

The major difference between IPv6 static routes and IPv4 static routes lies in their destination addresses and next hop addresses.

An IPv6 static route with destination address ::/0 (mask length 0) is a default IPv6 route. If the destination address of an IPv6 packet fails to match any entry in the routing table, a router selects the default IPv6 route to forward the IPv6 packet.

BFD for Static Route

Different from dynamic routing protocols, static routes do not have a detection mechanism. If a fault occurs on a network, an administrator must manually

address it. Bidirectional Forwarding Detection (BFD) for static route is introduced to associate a static route with a BFD session so that the BFD session can detect the status of the link that the static route passes through.

After BFD for static route is configured, each static route can be associated with a BFD session. In addition to route selection rules, whether a static route can be selected as the optimal route is subject to BFD session status.

- If a BFD session associated with a static route detects a link failure when the BFD session is Down, the BFD session reports the link failure to the system. The system then deletes the static route from the IP routing table.
- If a BFD session associated with a static route detects that a faulty link recovers when the BFD session is Up, the BFD session reports the fault recovery to the system. The system then adds the static route to the IP routing table again.
- By default, a static route can still be selected even though the BFD session associated with it is AdminDown (triggered by the **shutdown** command run either locally or remotely). However, if the system is restarted, the BFD session needs to be re-negotiated. Whether the static route can participate in route selection depends on the re-negotiated BFD status.

BFD for static route works in single-hop detection or multi-hop detection mode.

- Single-hop detection

In single-hop detection mode, the configured outbound interface and next hop address are the information about the directly connected next hop. The outbound interface associated with the BFD session is the outbound interface of the static route, and the peer address is the next hop address of the static route.

- Multi-hop detection

In multi-hop detection mode, only the next hop address is configured. Therefore, the static route must recurse to the directly connected next hop and outbound interface. The peer address of the BFD session is the original next hop address of the static route, and the outbound interface is not specified. In most cases, the original next hop is an indirect next hop. Multi-hop detection is performed on the static routes that support route recursion.

NOTE

For details about BFD, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series RouterFeature Description - Network Reliability*.

NQA for Static Route

Background

Static routes do not have a dedicated detection mechanism. If a link fails, the corresponding static route will not be automatically deleted from the IP routing table. In this case, intervention of a network administrator is required. This delays the link switchover and may cause lengthy service interruptions.

BFD for static route can use BFD sessions to monitor the link status of a static route. However, BFD for static route requires that both ends of a link support BFD. As a result, it cannot be implemented in some scenarios. NQA for static route can solve this problem.

Table 1-9 compares BFD for static route and NQA for static route.

Table 1-9 Comparison between BFD for static route and NQA for static route

Item	BFD for Static Route	NQA for Static Route
Detection mode	Bidirectional session	Unidirectional detection
Requirements for devices	Both ends must support BFD.	NQA is required on only one end.
Detection speed	Millisecond-level	Second-level

Related Concepts

NQA helps carriers monitor network quality of service (QoS) in real time, and can be used to diagnose the fault if a network fails.

NQA relies on a test instance to monitor the link status. The two ends of an NQA test are called the NQA client and the NQA server. An NQA test is initiated by the NQA client. NQA test results are classified into the following types:

- Success: The test is successful. It instructs the routing management module to set the status of the static route to active and add the static route to the routing table.
- Failed: The test fails. It instructs the routing management module to set the status of the static route to inactive and delete the static route from the routing table.
- No result: The test is running and no result has been obtained. If the test result is no result, the status of the static route is not changed.

For NQA details, see "System Monitor" in *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Feature Description*.

Implementation

NQA for static route associates an NQA test instance with a static route and uses the NQA test instance to monitor the link status. The routing management module determines whether a static route is active based on the NQA test result. If the static route is inactive, the routing management module deletes it from the IP routing table and selects a normal backup link for data forwarding, which prevents lengthy service interruptions.

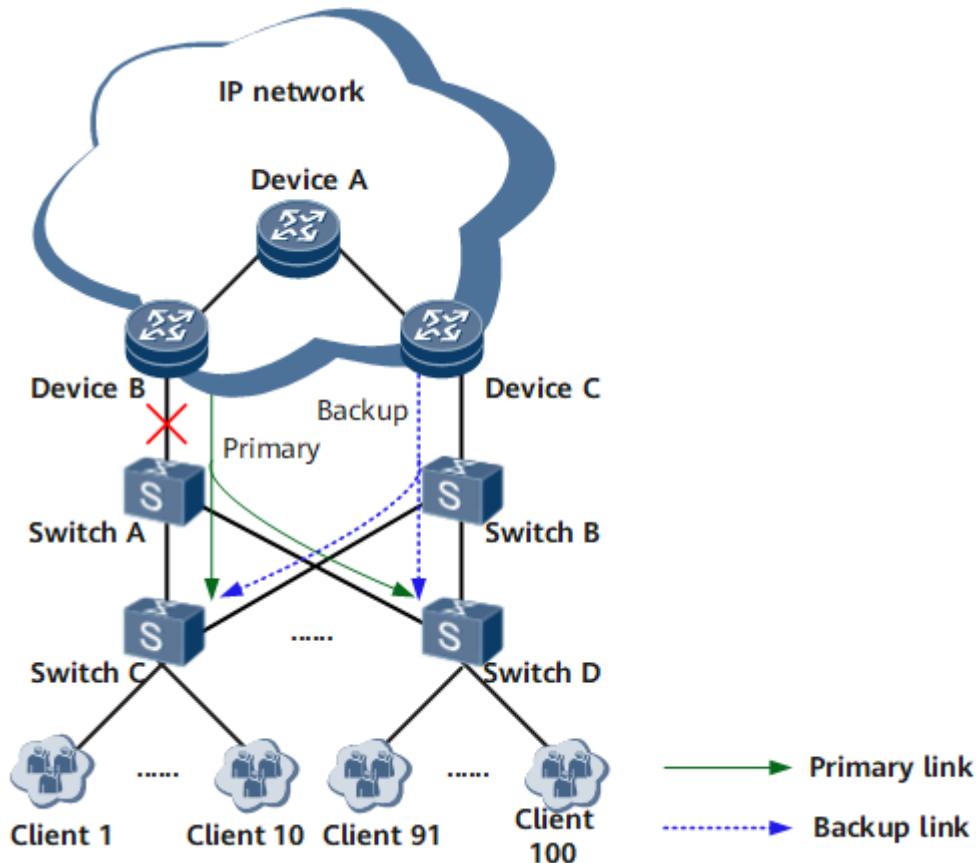

In **Figure 1-37**, each access switch is connected to 10 clients, and a total of 100 clients exist. Because no dynamic routing protocol can be used between DeviceB and clients, static routes to the clients need to be configured on DeviceB. To ensure network stability, the same configuration is performed on DeviceC for backup.

DeviceA, DeviceB, and DeviceC run a dynamic routing protocol and can learn routes from each other. On DeviceB and DeviceC, the dynamic routing protocol is configured to import static routes, and different costs are configured for the static

routes. In this way, DeviceA can learn the routes to clients from DeviceB and DeviceC through the dynamic routing protocol. DeviceA then determines the primary and backup links based on the costs.

NQA for static route is configured on DeviceB, and an NQA test instance is used to monitor the status of the primary link. If the primary link fails, the corresponding static route is deleted and downlink traffic switches to the backup link. When both the links are running properly, downlink traffic is preferentially transmitted along the primary link.

Figure 1-37 Network diagram of NQA for static route

NOTE

NQA test instances can monitor the links of IPv4 and IPv6 static routes. The mechanisms for monitoring IPv4 and IPv6 static routes are the same.

Each static route can be associated with only one NQA test instance.

Usage Scenario

NQA for static route applies to a network where BFD for static route cannot be deployed due to device limitations. For example, user devices access the network through the switch, OLT, DSLAM, MSAN, or xDSL mode.

Benefits

It can rapidly and periodically detect the link status of static routes and implement rapid primary/backup link switchovers, preventing lengthy service interruptions.

NQA Group for Static Route

Background

Static routes do not have a dedicated detection mechanism. If a link fails, the corresponding static route will not be automatically deleted from the IP routing table. In this case, intervention of a network administrator is required. This delays the link switchover and may cause lengthy service interruptions.

NQA for static route can monitor only a single link. To enable a static route to use NQA test instances to monitor multiple links, you can bind these NQA test instances to the same NQA group and associate the static route with the NQA group.

Related Concepts

NQA helps carriers monitor network quality of service (QoS) in real time, and can be used to diagnose and locate the fault if a network fails.

NQA relies on a test instance to monitor the link status. The two ends of an NQA test are called the NQA client and the NQA server. An NQA test is initiated by the NQA client. NQA test results are classified into the following types:

- Success: The test is successful. It instructs the routing management module to set the status of the static route to active and add the static route to the routing table.
- Failed: The test fails. It instructs the routing management module to set the status of the static route to inactive and delete the static route from the routing table.
- No result: The test is running and no result has been obtained. If the test result is no result, the status of the static route is not changed.

NOTE

For NQA details, see "System Monitor" in *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Feature Description*.

Implementation

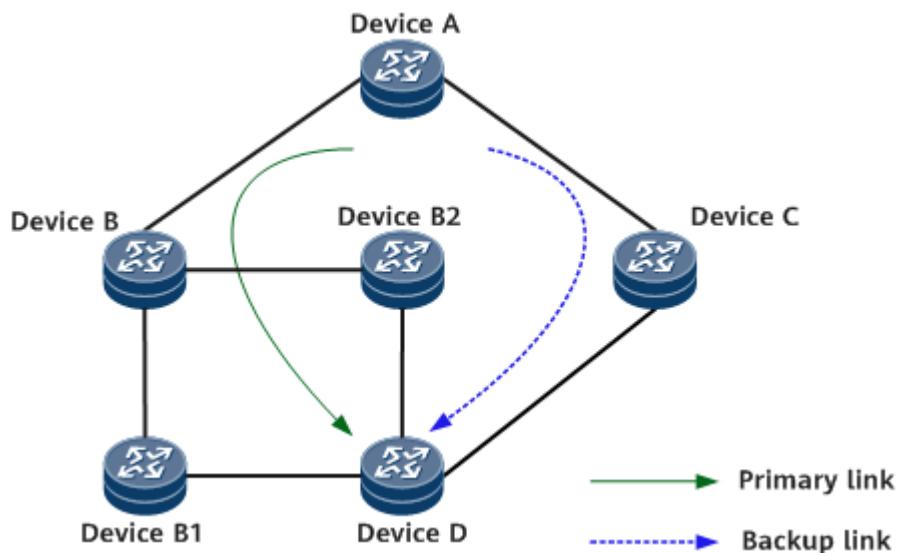

NQA group for static route monitors the link status of a static route through association between the static route and an NQA group that consists of multiple NQA test instances. The RM module determines whether the static route is active based on the test result of the NQA group. If the static route is inactive, the RM module deletes it from the IP routing table and selects an available backup link for data forwarding, which prevents lengthy service interruptions.

On the network shown in [Figure 1-38](#), default static routes are configured on Device B and Device C to divert traffic. To ensure network stability, the link between Device A and Device C work in backup mode.

Device B and Device D are connected through two links by way of Device B1 and Device B2. Device A, Device B, and Device C run BGP and can learn routes from each other. Device B and Device C are configured to import static routes into BGP and set different PrefVal values so that Device A can use BGP to learn user routes from Device B and Device C. Device A then determines the primary and backup links based on the PrefVal values.

NQA group for static route is configured on Device B, and two NQA test instances are bound to the NQA group to monitor the status of the two links from Device B to Device D. The status of the NQA group reflects the status of the primary link. If the primary link fails, advertisement of the static route is withdrawn so that user traffic is transmitted through the backup link. When both the links are running properly, user traffic is preferentially transmitted along the primary link.

Figure 1-38 Network diagram of NQA group for static route

NOTE

NQA groups can monitor the links of IPv4 and IPv6 static routes. The mechanisms for monitoring IPv4 and IPv6 static routes are the same.

Each static route can be associated with only one NQA group.

Usage Scenario

NQA group for static route applies to the scenario where whether a static route is active is determined by using multiple NQA test instances to monitor the status of multiple links.

Benefits

It can rapidly and periodically detect the link status of static routes and implement rapid primary/backup link switchovers, preventing lengthy service interruptions.

Static Route Permanent Advertisement

Background

When the link over which a static route runs fails, the static route will be deleted from the IP routing table to trigger a route re-selection. After a new route is selected, traffic is switched to the new route. Some carriers, however, may require that specific traffic always travel along a fixed link, regardless of the link status. Static route permanent advertisement is introduced to meet this service need.

Implementation

With static route permanent advertisement, a static route can still be advertised and added to the IP routing table for route selection even when the link over which the static route runs fails. After static route permanent advertisement is configured, the static route can be advertised and added to the IP routing table in both of the following scenarios:

- An outbound interface is configured for the static route, and the outbound interface has an IP address. Static route permanent advertisement is not affected no matter whether the outbound interface is Up.
- No outbound interface is configured for the static route. Static route permanent advertisement is not affected no matter whether the static route can obtain an outbound interface through route recursion.

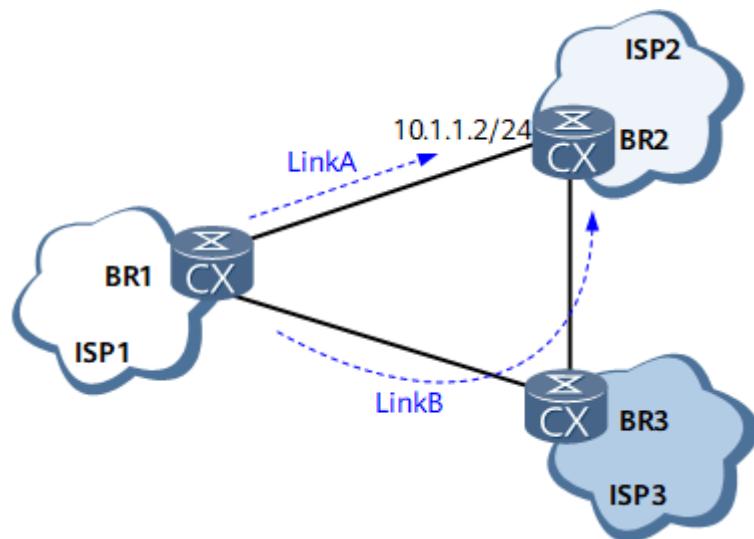

NOTE

After static route permanent advertisement is enabled, a static route always remains in the IP routing table regardless of route reachability. If the destination of the route becomes unreachable, traffic interruption occurs.

Typical Networking

On the network shown in [Figure 1-39](#), BR1, BR2, and BR3 belong to ISP1, ISP2, and ISP3 respectively. Two links (Link A and Link B) exist between BR1 and BR2, but ISP1 expects its service traffic destined for ISP2 to be always transmitted over Link A.

Figure 1-39 Networking with static route permanent advertisement

A direct EBGP peer relationship is established between BR1 and BR2. A static route is created on BR1, with 10.1.1.2/24 (IP address of BR2) as the destination address and the local interface connected to BR2 as the outbound interface.

Without static route permanent advertisement, Link A is used to transmit traffic. If Link A fails, BGP will switch the traffic to Link B.

With static route permanent advertisement, Link A is used to transmit traffic regardless of whether the destination is reachable through Link A. If Link A fails, no link switchover is performed, causing traffic interruption. To check whether the destination is reachable through the static route, ping the destination address of the static route to which static route permanent advertisement is applied.

Association Between LDP and Static Routes

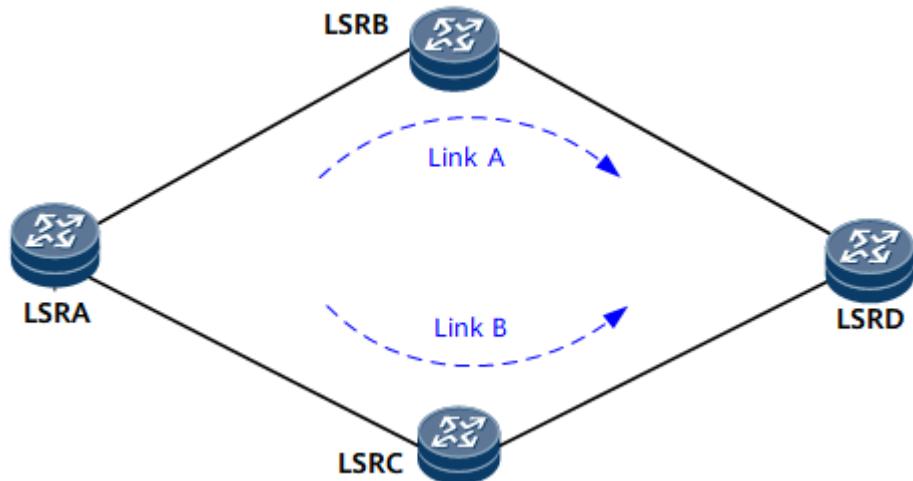

Background

On a network with a backup path between label switching routers (LSRs), packet loss may occur during a traffic switchover or switchback because the status of a static route is different from that of a Label Distribution Protocol (LDP) session. To resolve this problem, configure association between LDP and static routes.

Typical Networking

Figure 1-40 shows the typical networking of association between LDP and static routes. LSRA and LSRD interwork through static routes. Primary and backup static routes are deployed on LSRA, with the next-hop devices being LSRB and LSRC, respectively. Primary and backup LDP LSPs are established based on the static routes. The primary LSP uses Link A, and the backup LSP uses Link B. In normal cases, Link A is preferred. Association between LDP and static routes in switchover and switchback scenarios is described as follows.

Figure 1-40 Networking of LSP switching scenario where association between LDP and static routes is configured

Switchover scenario

In the switchover scenario, traffic of the primary static route is not switched to the backup link when the LDP session on the primary link fails (not because of a link fault). As a result, traffic on the LSP over the primary link is interrupted.

After an LDP session is established, LSP traffic travels along the primary link, Link A (LSRA → LSRB → LSRD). If the LDP session between LSRA and LSRB is interrupted, traffic of the primary LSP is switched immediately to the backup link, Link B (LSRA → LSRC → LSRD). However, because the link between LSRA and LSRB is normal, traffic of the primary static route is not switched to the backup link. The asynchronous state between LDP and the primary static route causes an LSP traffic interruption.

If association between LDP and static routes is enabled, traffic is automatically switched to the backup link when the LDP session goes Down, ensuring uninterrupted traffic forwarding.

Switchback scenario

In the switchback scenario, when the primary link recovers from a fault, the traffic of the primary static route is switched back to Link A earlier than the traffic of the primary LSP because the convergence of static routes is faster than that of LDP LSPs. As a result, the backup LSP on Link B cannot be used, and the LSP on Link A has not been set up yet. As a result, LSP traffic is interrupted.

If the link between LSRA and LSRB fails, traffic is switched immediately to the backup link, Link B (LSRA → LSRC → LSRD). After the link between LSRA and LSRB recovers, traffic of the primary static route is immediately switched back to Link A (LSRA → LSRB → LSRD). However, the backup LSP cannot be used, and the LSP on Link A has not recovered yet. As a result, traffic is interrupted.

If association between LDP and static routes is enabled, the static route on Link A becomes active only when the LDP session on Link A goes Up. In this manner, the states of the primary static route and LSP are asynchronous during the switchback, which prevents traffic loss.

Usage Scenario

Association between LDP and static routes applies to scenarios where a static route backup path exists between LSRs.

Benefits

Association between LDP and static routes ensures state consistency between LDP and static routes, prevents traffic loss, and improves network reliability.

1.1.2.2 IPv4 Static Route Configuration

Static routes are applicable to networks with simple structures. Properly configuring and using static routes can improve network performance and guarantee the required bandwidth for important applications.

1.1.2.2.1 Overview of IPv4 Static Routes

Configuring IPv4 static routes can implement the interworking of simple networks.

Definition

Static routes are special routes that are configured by network administrators.

Purpose

On a simple network, only static routes can ensure that the network runs properly. If a router cannot run dynamic routing protocols or cannot generate routes to a destination network, you can configure static routes on the router.

Route selection can be controlled using static routes. Properly configuring and using static routes can improve network performance and guarantee the required bandwidth for important applications. When a network fault occurs or the network topology changes, however, static routes must be changed manually by the administrator.

1.1.2.2 Configuration Precautions for IPv4 static route

Feature Requirements

Table 1-10 Feature requirements

Feature Requirements	Series	Models
Static routes cannot be recursed to SRv6 TE Policy Color-Only tunnels. If the route (such as a BGP route) on which the next hop of a static route is recursed uses a Color-Only tunnel, the static route inherits the Color-Only tunnel as the next hop. However, BFD for locator fast switching is not supported.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
The static routes to participate in FRR must have different priorities configured.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
When the number of configured static routes for load balancing exceeds the product specification limit, the preferred static route may change after the active preferred route is modified or the active/standby switchover is performed twice.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

Feature Requirements	Series	Models
Before you associate a static route with a BFD session, the session must have been created.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/ NetEngine 8000 X16/NetEngine 8000E X8/ NetEngine 8100 X
If recursion depth-based static route selection is configured, the number of static routes for load balancing may decrease. As a result, static routes may fail to implement load balancing.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/ NetEngine 8000 X16/NetEngine 8000E X8/ NetEngine 8100 X

Feature Requirements	Series	Models
<p>When static routes are deployed, the following features are mutually exclusive:</p> <ul style="list-style-type: none">1. BFD (Bidirectional Forwarding Detection) for static route2. NQA (Network Quality Analysis) for static route3. Association between static routes and EFM44. Permanent advertisement of static routes <p>Determine which feature to use based on the actual network conditions:</p> <ul style="list-style-type: none">■ BFD for static routes enables a static route to be bound to a BFD session. The BFD session detects the link status of the static route and determines whether to activate the static route.■ Deploying NQA for static routes uses NQA test instances to detect the status of the link where the static route resides and determines whether to activate the static route based on the NQA test results. NQA for static routes can be deployed in special scenarios, for example, when BFD is not applicable to links between different ISPs or a link segment does not support BFD.■ After EFM is associated with static routes, the system responds to the EFM Up/Down event of a specified interface and determines whether to activate static routes. This controls route advertisement and directs remote traffic.■ Permanent advertisement of static routes can be deployed if the customer wants to determine the forwarding path of service traffic so that traffic is not switched to another path even if a link fault occurs.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/ NetEngine 8000 X16/NetEngine 8000E X8/ NetEngine 8100 X

Feature Requirements	Series	Models
The route recursive-lookup tunnel command can be used to recurse IPv4 VPN static routes whose next hops are on the public network to tunnels on the public network. After this command is run, the system preferentially recurses a static route to an IP route. If no matching IP route is available for recursion, the system does not recurse the static route to a tunnel. If a matching BGP route is available for recursion, the static route recurses to the BGP route. If a matching non-BGP route is available for recursion, the static route recurses to a tunnel based on the tunnel policy. If a matching network segment (non-host route) is available for recursion, the network segment address is used to recurse the static route to a tunnel. Therefore, the static route can recurse to a public network tunnel based on the next hop address only if a matching non-BGP route corresponding to the next hop is available.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

1.1.2.2.3 Configuring IPv4 Static Routes

On a network, you can control route selection by configuring IPv4 Static Routes.

Usage Scenario

IPv4 static routes can be configured for a network with simple structure to achieve connectivity.

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports common static routes and those associated with VPN instances. The static routes associated with VPN instances are used to manage VPN routes. For details about VPN instances, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide - VPN*.

Pre-configuration Tasks

Before configuring IPv4 Static Routes, configure parameters of the link layer protocol and IP addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.

Creating IPv4 Static Routes

To create an IPv4 static route, configure its destination address, outbound interface, and next hop.

Context

When creating an IPv4 static route, you need the following information:

- Destination address and mask

In the **ip route-static** command, the IPv4 address is expressed in dotted decimal notation, and the mask is expressed either in dotted decimal notation or represented by the mask length.

- Outbound interface and next hop address

When creating a static route, you can specify *interface-type interface-name*, *nexthop-address*, or both. In addition, you can configure the Next-Table function, that is, only a VPN instance name (public in the case of the public network) is specified as the next hop of a static route, and no outbound interface or next hop address is specified. You can configure the parameters as required.

Actually, each routing entry requires a next hop address. Before sending a packet, a device needs to search its routing table for the route matching the destination address in the packet based on the longest match rule. The device can find the associated link layer address to forward the packet only when the next hop address of the packet is available.

When specifying an outbound interface, note the following rules:

- For a Point-to-Point (P2P) interface, if the outbound interface is specified, the next hop address is the address of the remote interface connected to the outbound interface. For example, when a GE interface is encapsulated with Point-to-Point Protocol (PPP) and obtains the remote IP address through PPP negotiation, you need to specify only the outbound interface rather than the next hop address.

- Non-Broadcast Multiple-Access (NBMA) interfaces are applicable to Point-to-Multipoint networks. Therefore, you need to configure IP routes and the mappings between IP addresses and link layer addresses. In this case, next hop IP addresses need to be configured.

- An Ethernet interface is a broadcast interface and a virtual-template (VT) interface can be associated with multiple virtual access interfaces. If the Ethernet interface or the VT interface is specified as the outbound interface of a static route, the next hop cannot be determined because multiple next hops exist. Therefore, do not specify an Ethernet interface or a VT interface as the outbound interface unless necessary. If you need to specify a broadcast interface (such as an Ethernet interface), a VT interface, or an NBMA interface as the outbound interface, you are recommended to specify the associated next hop address at the same time.

- Other attributes

You can configure different preferences for different static routes so that routing management policies can be flexibly applied. For example, when creating multiple routes to the same destination address, you can set the same preference for these routes to implement load balancing. You can also set different preferences to implement routing redundancy.

By configuring different tag values, you can classify static routes to implement different routing policies. For example, other protocols can import static routes with specified tag values based on routing policies.

If service traffic needs to be forwarded along a specified path, regardless of the link status, you can configure permanent advertisement of static routes by using **permanent**.

In network maintenance scenarios, static routes are required to verify services. If you do not want these static routes to be imported by other protocols, specify **no-advertise** to prevent these static routes from being advertised. If you set the destination address and the mask to all 0s (0.0.0.0 0.0.0.0) in the **ip route-static** command, a default route is configured.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Configure an IPv4 static route.

- Run one of the following commands to configure an IPv4 static route for the public network:
 - **ip route-static ip-address { mask | mask-length } { nexthop-address | nexthop6-address } [preference preference | tag tag] * [description text]**
 - **ip route-static ip-address { mask | mask-length } { interface-name | interface-type interface-number } [{ nexthop-address | nexthop6-address }] [preference preference | tag tag] * [description text]**
 - **ip route-static ip-address { mask | mask-length } vpn-instance vpn-instance-name [preference preference | tag tag] * description text**
 - **ip route-static ip-address { mask | mask-length } vpn-instance vpn-instance-name { nexthop-address | nexthop6-address } [preference preference | tag tag] * [description text]**
- Run one of the following commands to configure an IPv4 static route for a VPN instance:
 - **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { interface-type interface-number } [nexthop-address] [preference preference | tag tag] * [description text]**
 - **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } nexthop-address [preference preference | tag tag] * [description text]**
 - **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { public | vpn-instance vpn-destination-name } [preference preference | tag tag] * [description text]**
 - **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } vpn-instance vpn-destination-name nexthop-address [preference preference | tag tag] * [description text]**
- To configure an IPv4 static route in the topology instance, run the **ip route-static topology topology-name ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] } [preference preference | tag tag] * [no-advertise | no-install] [description text]** command.

NOTE

If the outbound interface of a static route is a broadcast interface or an NBMA interface, the next hop of the outbound interface must be specified.

Step 3 Run commit

The configuration is committed.

----End

(Optional) Setting the Default Priority for IPv4 Static Routes

You can change the default priority for IPv4 static routes.

Context

After an IPv4 static route is configured, the default priority is used if no priority is specified for the static route. After the default priority is re-set, the new default priority takes effect only on new IPv4 static routes.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ip route-static default-preference *preference*

The default preference value is configured for static routes.

By default, the priority of IPv4 static routes is lower than those of OSPF and IS-IS routes. To allow IPv4 static routes to take effect when OSPF or IS-IS routes exist, configure the default priority of IPv4 static routes to be higher than that of OSPF or IS-IS routes before you configure IPv4 static routes. A smaller preference value indicates a higher priority.

Step 3 Run commit

The configuration is committed.

----End

(Optional) Configuring Recursion Depth-based Static Route Selection

To prevent inter-board service transmission or routing loop in a static route scenario, configure recursion depth-based static route selection.

Context

Among static routes with the same prefix but different recursion depths, the static routes with shorter recursion depths are more stable. After recursion depth-based static route selection is configured, the system selects the static routes with shorter recursion depths as active routes and delivers them to the Forwarding Information Base (FIB) table. The other routes become inactive.

To prevent inter-board service transmission or routing loop in a static route scenario, configure recursion depth-based static route selection.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip route-static selection-rule relay-depth**

Recursion depth-based static route selection is configured.

Step 3 Run **commit**

The configuration is committed.

----End

(Optional) Configuring a Device to Iterate Static Routes to ARP Vlink Routes

To prevent traffic loss caused by a black-hole route in a scenario where a Layer 2 VPN accesses a Layer 3 VPN, configure devices to iterate static routes to ARP Vlink routes.

Context

Configuring a device to iterate static routes to ARP Vlink routes prevents traffic loss caused by a black-hole route in a scenario where a Layer 2 VPN accesses a Layer 3 VPN.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip route recursive-lookup arp vlink-direct-route protocol static**

The device is configured to iterate static routes to ARP Vlink routes.

In a scenario where a Layer 2 VPN accesses a Layer 3 VPN, to configure a device to recurse static routes to ARP Vlink routes, run the **ip route-static** command with **recursive-lookup host-route** specified and **ip route recursive-lookup arp vlink-direct-route protocol static**.

Step 3 Run **commit**

The configuration is committed.

----End

(Optional) Enabling a Device to Recurse Static Routes to SRv6 Routes

By default, a device cannot recurse static routes to SRv6 routes. In an L3VPNv4 HoVPN over SRv6 BE, L3VPNv4 HoVPN over SRv6 TE Policy, EVPN L3VPN HoVPN over SRv6 BE, or EVPN L3VPN HoVPN over SRv6 TE Policy scenario, you can configure static routes to recurse to SRv6 routes to prevent traffic black holes.

Context

In an L3VPNv4 HoVPN over SRv6 BE, L3VPNv4 HoVPN over SRv6 TE Policy, EVPN L3VPN HoVPN over SRv6 BE, or EVPN L3VPN HoVPN over SRv6 TE Policy scenario,

if the next hop of a default static route on the SPE is the SPE itself and the link between the SPE and the NPE fails, the UPE cannot detect the link fault. As a result, a traffic black hole occurs after traffic reaches the SPE. To resolve this problem, you need to specify the NPE's address (public or private) as the next-hop address of the default static route on the SPE. In this manner, the validity of the static route depends on whether the link between the SPE and NPE is available. In addition, you need to enable the SPE to recurse static routes to SRv6 routes. This configuration allows the SPE to withdraw this inactive route when the SPE-NPE link fails so that the UPE can detect the route withdrawal and no longer sends traffic to the SPE, thereby preventing a traffic black hole.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip route-static recursive-lookup inherit-label-route segment-routing-ipv6**

The device is enabled to recurse IPv4 static routes to SRv6 routes.

Step 3 Run **commit**

The configuration is committed.

----End

(Optional) Preventing an IPv4 Static Route from Being Selected If the BFD Session Associated with It Is in the AdminDown State

This section describes how to configure the router not to select an IPv4 static route if the BFD session associated with it is in the AdminDown state. This ensures that Huawei devices can interwork with non-Huawei devices.

Context

By default, an IPv4 static route can still be selected by Huawei devices even though the BFD session associated with it is in the AdminDown state, but not by non-Huawei devices. As a result, Huawei devices cannot interwork with non-Huawei devices.

To address this problem, run the **ip route-static track bfd-session admindown invalid** command to configure the router not to select the IPv4 static route if the BFD session associated with it is in the AdminDown state.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip route-static track bfd-session session-name *bfd-name* admindown invalid**

The router has been configured not to select the IPv4 static route if the BFD session associated with it is in the AdminDown state.

Step 3 Run commit

The configuration is committed.

----End

Verifying the IPv4 Static Route Configuration

After configuring an IPv4 static route, verify the configuration.

Prerequisites

An IPv4 static route has been configured.

Procedure

- Run the **display ip routing-table** command to check brief information about the IPv4 routing table.
- Run the **display ip routing-table verbose** command to check detailed information about the IPv4 routing table.
- Run the **display ip routing-table protocol** command to check information about routes of a specified routing protocol.

----End

1.1.2.2.4 Configuring IPv4 Floating Static Routes

Configuring IPv4 floating static routes helps to implement route backup and improve network reliability.

Usage Scenario

If there is a route to a specific destination, you can configure a static route with a low preference to implement route backup, which improves network reliability. This static route with a lower preference is called a floating static route. It is activated to forward packets only when the optimal route fails. When the optimal route recovers, this static route becomes inactive.

Floating static routes are used as follows:

- Two static routes with the same destination address but different priorities are configured, and the one with the lower priority functions as a backup.
- When a route of a dynamic routing protocol to a destination address exists, you can configure a static route to the destination address for data service forwarding temporarily if the dynamic routing protocol restarts.

Pre-configuration Tasks

Before configuring IPv4 floating static routes, configure link layer protocol parameters and IP addresses for interfaces and ensure that the status of the link layer protocol on the interfaces is Up.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run either of the following commands as required:

- To configure an IPv4 floating static route on the public network, run the **ip route-static ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } [preference preference | tag tag]* [description text]** command.
- To configure an IPv4 floating static route on a VPN, run the **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } [preference preference | tag tag]* [description text]** command.
- To configure an IPv4 floating static route in a topology instance, run the **ip route-static topology topology-name ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] } [preference preference | tag tag]* [description text]** command.

The **preference** parameter specifies a route priority. The greater the value, the lower the priority. Therefore, make sure that the priority value of the floating static route is greater than that of the primary route.

Step 3 Run commit

The configuration is committed.

----End

Checking the Configurations

After the configuration is complete, check the configuration results.

- Run the **display ip routing-table ip-address [mask | mask-length]** command to check configurations about the optimal IPv4 static route to the specified destination network segment.
- Run the **display current-configuration | include static** command to check the configurations about the current static route.

1.1.2.2.5 Configuring Association between LDP and Static Routes

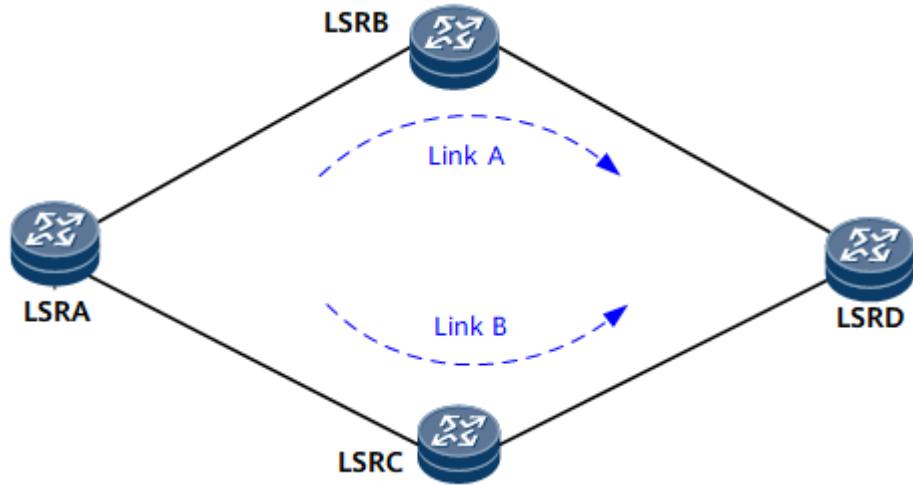

On an MPLS network with primary and secondary LSPs established by label switched routers (LSRs) using static routes, association between LDP and static routes prevents MPLS traffic from being interrupted during traffic switching between the primary and secondary LSPs.

Usage Scenario

On an MPLS network with primary and secondary LSPs established by LSRs using static routes, association between LDP and static routes prevents traffic from being interrupted during traffic switchover from the primary LSP to the secondary

LSP when the LDP session on the primary link fails (not because of a link fault) or during traffic switchback when the primary link recovers from a fault. In [Figure 1-41](#), LSRA and LSRD interwork through static routes. Primary and secondary static routes are deployed on LSRA, with the next-hop devices being LSRB and LSRC, respectively. Primary and secondary LDP LSPs are established based on the static routes. The primary LSP uses Link A, and the secondary LSP uses Link B. In normal cases, Link A is preferred. Association between LDP and static routes in switchover and switchback scenarios is described as follows.

Figure 1-41 Networking for association between LDP and static routes

Switchover scenario

In the switchover scenario, traffic of the primary static route is not switched to the secondary link when the LDP session on the primary link fails (not because of a link fault). As a result, traffic on the LSP over the primary link is interrupted.

After an LDP session is established, LSP traffic travels along the primary link, Link A (LSRA → LSRB → LSRD). If the LDP session between LSRA and LSRB is interrupted, traffic of the primary LSP is switched immediately to the secondary link, Link B (LSRA → LSRC → LSRD). However, because the link between LSRA and LSRB is normal, traffic of the primary static route is not switched to the secondary link. The asynchronous state between LDP and the primary static route causes an LSP traffic interruption.

If association between LDP and static routes is enabled, traffic is automatically switched to the secondary link when the LDP session goes Down, ensuring uninterrupted traffic forwarding.

Switchback scenario

In the switchback scenario, when the primary link recovers from a fault, the traffic of the primary static route is switched back to Link A earlier than the traffic of the primary LSP because the convergence of static routes is faster than that of LDP LSPs. As a result, the secondary LSP on Link B cannot be used, and the LSP on Link A has not been set up yet. As a result, LSP traffic is interrupted.

If the link between LSRA and LSRB fails, traffic is switched immediately to the secondary link, Link B (LSRA → LSRC → LSRD). After the link between LSRA and LSRB recovers, traffic of the primary static route is immediately switched back to

Link A (LSRA → LSRB → LSRD). However, the secondary LSP cannot be used, and the LSP on Link A has not recovered yet. As a result, traffic is interrupted.

If association between LDP and static routes is enabled, the static route on Link A becomes active only when the LDP session on Link A goes Up. In this manner, the states of the primary static route and LSP are asynchronous during the switchback, which prevents traffic loss.

 NOTE

Only the static routes with outbound interfaces specified can be associated with LDP.

Pre-configuration Tasks

Before configuring association between LDP and static routes, complete the following tasks:

- Enable MPLS.
- Enable MPLS LDP globally and on interfaces.
- Ensure that LDP sessions are set up between devices.

Procedure

- Enable association between LDP and static routes.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **ip route-static [vpn-instance vpn-instance-name] ip-address { mask | mask-length } interface-type interface-number [next-hop-address] [preference preference | tag tag] * ldp-sync [description text]**
Association between LDP and static routes is enabled.
 - c. Run **commit**
The configuration is committed.
- (Optional) Set a Hold-down timer.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface interface-type interface-number**
The outbound interface view of the primary link of the static route is displayed.
 - c. Run **static-route timer ldp-sync hold-down { timer | infinite }**
A period in which the static route is inactive and waits for the establishment of an LDP session is set.
 - d. Run **commit**
The configuration is committed.

 NOTE

The preceding configurations need to be performed on both ends of the primary and secondary links.

----End

Checking the Configurations

After configuring association between LDP and static routes, run the **display static-route ldp-sync** command.

1.1.2.2.6 Configuring IPv4 Static Route Detection

With IPv4 static route detection, if a link through which an IPv4 static route travels fails, a rapid link switchover is performed, preventing lengthy service interruptions.

Usage Scenario

Unlike dynamic routes, static routes do not have a detection mechanism. As a result, administrator intervention is required if a fault occurs on the network. Static route detection methods can be used to quickly detect link faults. If a link fails, a link switchover is performed quickly to prevent lengthy service interruption.

The following IPv4 static route detection methods are available:

- **BFD for IPv4 static routes:** After BFD for IPv4 static routes is configured, each static route can be bound to a BFD session. BFD for IPv4 static routes implements millisecond-level detection. BFD is classified as static BFD or dynamic BFD.
- **Network quality analysis (NQA) for IPv4 static routes:** Although BFD for IPv4 static routes implements fast link fault detection, it cannot be deployed in some scenarios (when Layer 2 devices exist on the network, for example) because both ends of the link must support BFD. NQA for IPv4 static routes, however, can monitor the link status of a static route even when only one end supports NQA. NQA for IPv4 static routes implements second-level detection.
- **Association between Ethernet in the First Mile (EFM) and IPv4 static routes:** After EFM OAM is enabled, EFM can be associated with IPv4 static routes. EFM for IPv4 static routes enables the system to respond to interface up or down events and determine whether to activate static routes. This mechanism controls route advertisement and ensures that the traffic from the remote end can be correctly forwarded.

Only one of the preceding static route detection methods can be deployed. Therefore, choose one based on the live network requirements.

Pre-configuration Tasks

Before configuring IPv4 static route detection, configure link-layer protocol parameters and IP addresses for interfaces to ensure that the link layer protocol of each interface is up.

Configuring Dynamic BFD for IPv4 Static Routes

Dynamic BFD for IPv4 static routes enables devices to fast detect link changes, improving network reliability.

Usage Scenario

To use BFD sessions to provide link detection for IPv4 static routes on the public network, you can bind IPv4 static routes to BFD sessions. One IPv4 static route can be bound to one BFD session.

Optimal IPv4 static routes are delivered to the forwarding table for packet forwarding. However, IPv4 static routes cannot detect the status of the link to the next hop. You can bind IPv4 static routes to BFD sessions. A BFD session can fast detect changes over a link and inform the routing management system of the changes. The routing management system immediately deletes the IPv4 static route that is bound to the BFD session from the forwarding table and recalculates another active route. In this manner, fast route convergence is implemented.

Pre-configuration Tasks

Before configuring dynamic BFD for static routes, configure parameters of the link layer protocol and IP addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **bfd**

Global BFD is enabled on the local device.

Running the **undo bfd** command will delete the parameters of the BFD session bound to the static route. As a result, the static route status may change, and services may be interrupted.

Step 3 Run **quit**

Return to the system view.

Step 4 (Optional) Run **ip route-static default-bfd [min-rx-interval min-rx-interval] [min-tx-interval min-tx-interval] [detect-multiplier multiplier] ***

Global BFD parameters are configured for IPv4 static routes.

Step 5 Run **ip route-static bfd [interface-type interface-number | vpn-instance vpn-instance-name] nexthop-address [local-address address] [min-rx-interval min-rx-interval] [min-tx-interval min-tx-interval] [detect-multiplier multiplier] ***

The BFD parameters are set for an IPv4 static route.

 NOTE

If *interface-type interface-number* is not set, **local-address** *address* must be specified.

If *interface-type interface-number* is specified, the BFD session monitors the active status of the corresponding link on the specified interface. If **local-address** *address* is specified, the BFD session monitors the active status of the corresponding link.

If none of **min-rx-interval**, **min-tx-interval**, or **detect-multiplier** is specified, the default values of the global BFD parameters are used.

Step 6 Run either of the following commands as required:

- Run **ip route-static** *ip-address* { *mask* | *mask-length* } { *nexthop-address* | *interface-type interface-number* [*nexthop-address*] | **vpn-instance** *vpn-instance-name* *nexthop-address* } **bfd enable** [**description** *text*]
A public network IPv4 static route is bound to a BFD session.
- Run **ip route-static** **vpn-instance** *vpn-source-name* *destination-address* { *mask* | *mask-length* } { *nexthop-address* | *interface-type interface-number* [*nexthop-address*] | **vpn-instance** *vpn-instance-name* *nexthop-address* } **bfd enable** [**description** *text*]
A VPN network IPv4 static route is bound to a BFD session.

 NOTE

The outbound interface and next hop IP address specified when binding the IPv4 static route to a BFD session must be the same as those specified when configuring BFD parameters for the IPv4 static route.

Step 7 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

Run the following commands to check the previous configuration.

- Run the **display bfd session** { **all** | **discriminator** *discr-value* } [**verbose**] command to check detailed BFD session information.
- Run the **display current-configuration** | **include bfd** command to check configurations of BFD for static routes.

You can check the information about a BFD session only after parameters of the BFD session are set and the BFD session is established.

If a BFD session has been established, the status of the BFD session is Up. Run the **display current-configuration** | **include bfd** command in the system view, and you can view that the BFD session has been bound to a static route.

Configuring Static BFD for IPv4 Static Routes

Static BFD for IPv4 static routes enables devices to fast detect link changes, improving network reliability.

Usage Scenario

To use BFD sessions to provide link detection for IPv4 static routes on the public network, you can bind IPv4 static routes to BFD sessions. One IPv4 static route can be bound to one BFD session.

Optimal IPv4 static routes are delivered to the forwarding table for packet forwarding. However, IPv4 static routes cannot detect the status of the link to the next hop. You can bind IPv4 static routes to BFD sessions. A BFD session can fast detect changes over a link and inform the routing management system of the changes. The routing management system immediately deletes the IPv4 static route that is bound to the BFD session from the forwarding table and recalculates another active route. In this manner, fast route convergence is implemented.

Pre-configuration Tasks

Before configuring static BFD for IPv4 static routes, complete the following tasks:

- Configure parameters of the link layer protocol and IP addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.

Procedure

- Configure a BFD Session.
 - Run **system-view**
The system view is displayed.
 - Run **bfd**
BFD is globally enabled.
 - Run **quit**
The system view is displayed.
 - Run **bfd session-name bind peer-ip peer-ip**
The binding between a BFD session and a peer IP address is created and the BFD session view is displayed.
 - Run **discriminator local discr-value**
The local discriminator of a static BFD session is set.
 - Run **discriminator remote discr-value**
The remote discriminator of a static BFD session is set.

NOTE

For details of optional procedures when configuring BFD session, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide - Network Reliability*.

- Run **commit**
The configuration is committed.
- Associating an IPv4 Static Route with a BFD Session.
 - Run **system-view**
The system view is displayed.

b. Run either of the following commands as required:

- Run **ip route-static ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } track bfd-session cfg-name [description text]**
A BFD session is bound to an IPv4 static route on the public network.
- Run **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } track bfd-session cfg-name [description text]**
A BFD session is bound to an IPv4 static route on the VPN network.

c. Run **commit**

The configuration is committed.

----End

Verifying the Configuration

Run the following commands to check the previous configuration.

- Run the **display bfd session { all | discriminator descr-value } [verbose]** command to check information about the BFD session.
- Run the **display current-configuration | include bfd** command to check the configuration of BFD for static routes.

You can check the information about a BFD session only after parameters of the BFD session are set and the BFD session is established.

If a BFD session has been established, the status of the BFD session is Up. Run the **display current-configuration | include bfd** command in the system view, and you can see that the BFD session has been bound to a static route.

Configuring NQA for IPv4 Static Routes

If an IPv4 static route is associated with a network quality analysis (NQA) test instance, NQA tests the link status periodically. If NQA detects a fault along the associated IPv4 static route, the IPv4 static route is deleted, and traffic is switched to another route.

Usage Scenario

On live networks, the link status of IPv4 static routes must be monitored in real time so that a link switchover can be performed immediately if a link fails. Bidirectional Forwarding Detection (BFD) for IPv4 static routes can implement detection within milliseconds. However, BFD for IPv4 static routes requires that both ends of a link support BFD.

NQA for IPv4 static routes can monitor the link status of static routes as long as one end supports NQA.

If a link fails, an NQA test instance immediately detects the fault and instructs the routing management module to delete the IPv4 static route associated with the

NQA test instance from the IP routing table. Traffic is then forwarded over another link.

 NOTE

Currently, NQA test instances of only the ICMP or TCP type can be associated with static routes to implement fast fault detection.

Pre-configuration Tasks

Before configuring NQA for IPv4 static routes, configure parameters of the link layer protocol and IP addresses for interfaces and ensure that the link layer protocol on the interfaces is up.

Procedure

- Configure an NQA test instance of the ICMP or TCP type.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **nqa test-instance admin-name test-name**
An NQA test instance is created, and the test instance view is displayed.

 NOTE

Running the **undo nqa all-test-instance** command will delete the parameters of the NQA test instance bound to the static route. As a result, the static route status may change, and services may be interrupted.

- c. Run **test-type { icmp | tcp }**
The type of the test instance is set to ICMP or TCP.
- d. Run **destination-address ipv4 destAddress**
A destination address is configured.

In an NQA test instance, you can specify an NQA server by running the **destination-address** command to configure a destination address for the NQA test instance.

- e. Run any of the following commands to start an NQA test instance:

- **start at [yyyy/mm/dd] hh:mm:ss [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start delay { seconds second | hh:mm:ss } [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start now [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start daily hh:mm:ss to hh:mm:ss [begin { yyyy/mm/dd | yyyy-mm-dd }] [end { yyyy/mm/dd | yyyy-mm-dd }]**

 NOTE

For details of optional procedures when configuring an ICMP NQA test instance, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide - System Monitor*.

f. Run **commit**

The configuration is committed.

- Associate an IPv4 static route with an NQA test instance.

a. Run **system-view**

The system view is displayed.

- Perform either of the following operations to associate an IPv4 static route with the NQA test instance.

- To configure an IPv4 static route on the public network and associate the route with an NQA test instance, run the **ip route-static ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address | vpn-instance vpn-destination-name }** [**preference preference | tag tag**] * **track nqa admin-name test-name [description text]** command.
- To configure an IPv4 static route on a VPN and associate the route with an NQA test instance, run the **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { nexthop-address [public] | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address | vpn-instance vpn-destination-name | public }** [**preference preference | tag tag**] * **track nqa admin-name test-name [description text]** command.

c. Run **commit**

The configuration is committed.

 NOTE

Precautions for associating a static route with an NQA test instance are as follows:

- The destination address of an NQA test instance cannot be the destination address of an associated static route.
- If the static route associated with one NQA test instance is associated with another NQA test instance, the association between the static route and the original NQA test instance is deleted.
- An NQA test instance must have been created before you associate it with a static route.

----End

Verifying the Configuration

Run the following commands to check the previous configuration.

- Run the **display current-configuration | include nqa** command to check the configurations of NQA for static routes.

- Run the **display nqa results [test-instance admin-name test-name]** command to check the NQA test results.

 NOTE

The NQA test results cannot be displayed automatically. You need to run the **display nqa results** command to view the results.

Configuring NQA Group for IPv4 Static Route

After an IPv4 static route is associated with an NQA group, if the NQA group detects a link fault, it withdraws the IPv4 static route, triggering traffic switching and ensuring network stability.

Usage Scenario

On live networks, the status of IPv4 static routes needs to be monitored in real time to ensure network stability. If the link status changes, a primary/backup link switchover is performed. NQA for IPv4 static route can monitor only a single link. To enable a static route to use NQA test instances to monitor multiple links, you can bind these NQA test instances to the same NQA group and associate the static route with the NQA group.

If a link fault occurs, the NQA group can collect statistics on the status changes of all NQA test instances bound to the NQA group and determine whether to change its status according to the configured operation. When the status of the NQA group changes, the NQA group instructs the RM module to delete the IPv4 static route associated with the NQA group from the IP routing table. Traffic is then forwarded along another path, implementing a link switchover.

Pre-configuration Tasks

Before configuring NQA group for IPv4 static route, complete the following task:

- Configure link-layer protocol parameters and IP addresses for interfaces to ensure that the link layer protocol of each interface is up.

Procedure

- Configure multiple NQA test instances of the ICMP or TCP type.
 - Run **system-view**
The system view is displayed.
 - Run **nqa test-instance admin-name test-name**
An NQA test instance is created, and the test instance view is displayed.
 - Run **test-type { icmp | tcp }**
The test instance type is set to ICMP or TCP.
 - Run **destination-address ipv4 destAddress**
A destination address is configured.
In an NQA test instance, you can specify the destination end by running the **destination-address** command to configure a destination address for the NQA test instance.
 - Run any of the following commands to start an NQA test instance:

- **start at [yyyy/mm/dd] hh:mm:ss [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start delay { seconds second | hh:mm:ss } [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start now [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start daily hh:mm:ss to hh:mm:ss [begin { yyyy/mm/dd | yyyy-mm-dd }] [end { yyyy/mm/dd | yyyy-mm-dd }]**

 **NOTE**

For more optional configurations of NQA test instances, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide - System Monitor*.

- f. Run **commit**

The configuration is committed.
 - g. Repeat the preceding steps to configure multiple NQA test instances of the ICMP or TCP type.
- Bind the preceding NQA test instances to an NQA group.
 - a. Run **system-view**

The system view is displayed.
 - b. Run **nqa group group-name**

An NQA group is created, and the NQA group view is displayed.
 - c. Run **nqa test-instance admin-name test-name**

An NQA test instance is bound to the NQA group.

Run this command multiple times to bind multiple NQA test instances to the NQA group.

 **NOTE**

The NQA test instances bound to the same NQA group must be of the same type: ICMP or TCP.

- d. Run **operator { and | or }**

The operation type between test instances in the NQA group is set to AND or OR.

By default, the operation type between test instances is **or**.
 - e. (Optional) Run **description string**

A description is configured for the NQA group.
 - f. Run **commit**

The configuration is committed.
- Bind an IPv4 static route to the NQA group.

a. Run **system-view**

The system view is displayed.

b. Bind an IPv4 static route to the NQA group.

- To configure an IPv4 static route on the public network and associate the route with the NQA group, run the **ip route-static ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } [preference preference | tag tag] * track nqa-group group-name [description text]** command.
- To configure an IPv4 static route on a VPN and associate the route with the NQA group, run the **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { nexthop-address [public] | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } [preference preference | tag tag] * track nqa-group group-name [description text]** command.

c. Run **commit**

The configuration is committed.

When configuring NQA group for IPv4 static route, pay attention to the following points:

- The destination address of an NQA group cannot be the destination address of an associated static route.
- If a static route is associated with another NQA group, the association between the static route and the current NQA group is removed.
- A static route cannot be associated with an NQA group that has not been created.

----End

Verifying the Configuration

After the configuration is complete, verify it.

- Run the **display static-route routing-table** command to check information about static routes.
- Run the **display current-configuration | include nqa-group** command to check the configurations of NQA group for IPv4 static route.
- Run the **display nqa group [group-name]** command to check the test result of the NQA group.

The test result of the NQA group cannot be displayed automatically. You need to run the **display nqa group** command to view the result.

Associating EFM with IPv4 Static Routes

After EFM is associated with IPv4 static routes, the system determines whether to activate the static routes based on the EFM session status.

Usage Scenario

After EFM is associated with IPv4 static routes, the system responds to EFM Up/Down events on a specified interface and determines whether to activate static routes. In this manner, route advertisement is controlled and remote traffic is forwarded.

On MANs, EFM is mainly used between customer edges (CEs) and underlayer provider edges (UPEs) to ensure the reliability and stability of connections between user networks and carrier networks. EFM monitors and rectifies faults on P2P Ethernet physical links or simulated links. It is recommended that EFM be used on user access networks.

Pre-configuration Tasks

Before associating EFM with IPv4 static routes, complete the following tasks:

- Configure link-layer protocol parameters and IP addresses for interfaces to ensure that the link layer protocol of each interface is up.
- Configure EFM OAM. For configuration details, see "Network Reliability" in *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide*.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Associate EFM with IPv4 static routes.

- To associate EFM with an IPv4 static route on the public network, run the **ip route-static ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } [preference preference | tag tag] * track efm-state interface-type interface-number [description text]** command.
- To associate EFM with an IPv4 static route in a VPN instance, run the **ip route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } [preference preference | tag tag] * track efm-state interface-type interface-number [description text]** command.

Step 3 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

Run the following commands to check the previous configuration.

- Run the **display efm session { all | interface interface-type interface-number }** command to check information about EFM OAM on a specified interface.

- Run the **display current-configuration | include efm** command to check configurations of association between EFM and IPv4 static routes.

1.1.2.2.7 Configuring FRR for IPv4 Static Routes

Fast reroute (FRR) is applicable to services that are sensitive to packet delay and packet loss. FRR can be configured for IPv4 static routes to protect traffic using backup links.

Usage Scenario

FRR is applicable to IP services that are sensitive to delay and packet loss. FRR minimizes the impact of link faults on services.

You can specify different priorities for different static routes to implement FRR for static routes. Routes with the same destination IP address but different priorities can back up each other.

Pre-configuration Tasks

Before configuring FRR for IPv4 static routes, complete the following tasks:

- Configure parameters of the link layer protocol and IP addresses for interfaces and ensure that the link layer protocol on the interfaces is Up.
- Configure multiple routes with the same destination IP address but different priorities.
- Configure dynamic BFD for IPv4 static routes** or **configure static BFD for IPv4 static routes** to speed up fault detection.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip route-static frr [vpn-instance vpn-instance-name]**

FRR is enabled for public or VPN IPv4 static routes.

NOTE

To implement route backup by configuring FRR for static routes, specify different priorities for these static routes.

If FRR for static routes and BFD are both configured and a static route has an Ethernet interface as its outbound interface but has no next hop address, FRR cannot be implemented between this static route and those with next hop addresses. To implement FRR between them, specify a next hop address for this route.

Step 3 Run **commit**

The configuration is committed.

----End

Checking the Configurations

Run the following commands to check the previous configuration.

- Run the **display ip routing-table verbose** command to check detailed information about the backup outbound interface and the backup next hop in the routing table.
- Run the **display ip routing-table ip-address [mask | mask-length] [longer-match] verbose** command to check detailed information about the backup outbound interface and the backup next hop in the routing table.
- Run the **display ip routing-table ip-address1 { mask1 | mask-length1 } ip-address2 { mask2 | mask-length2 } verbose** command to check detailed information about the backup outbound interface and the backup next hop in the routing table.

1.1.2.2.8 Configuration Examples for IPv4 Static Routes

This section provides configuration examples of IPv4 static routes.

Example for Configuring IPv4 Static Routes

You can configure IPv4 static routes to interconnect any two devices on an IPv4 network.

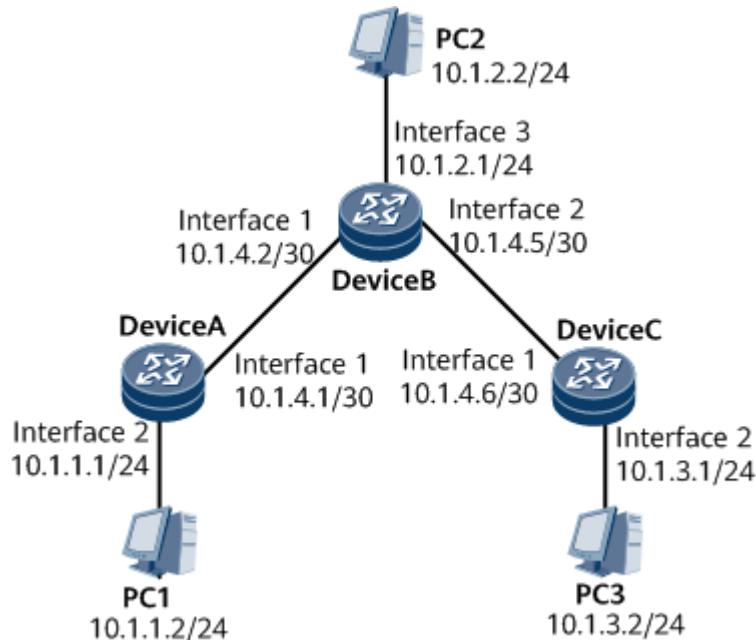

Networking Requirements

Figure 1-42 shows the IP addresses and masks of interfaces and hosts. It is required that any two hosts in **Figure 1-42** communicate through static routes.

Figure 1-42 Networking for configuring IPv4 static routes

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

Precautions

When configuring an IPv4 static route, specify a next-hop address if the outbound interface is of the broadcast type.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure IPv4 addresses for interfaces on each router.
2. Configure an IPv4 static route and a default route on each router.
3. Configure the IPv4 default gateway on each host so that any two hosts communicate with each other.

Data Preparation

To complete the configuration, you need the following data:

- Default route with 10.1.4.2 as the next hop on Device A
- Static route to 10.1.1.0 with 10.1.4.1 as the next hop on Device B
- Static route to 10.1.3.0 with 10.1.4.6 as the next hop on Device B
- Default route with 10.1.4.5 as the next hop on Device C
- Default gateways of PC1, PC2, and PC3

Procedure

Step 1 Configure an IP address for each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure static routes.

Configure an IPv4 default route on Device A.

```
[~DeviceA] ip route-static 0.0.0.0 0.0.0.0 10.1.4.2  
[*DeviceA] commit
```

Configure two IPv4 static routes on Device B.

```
[~DeviceB] ip route-static 10.1.1.0 255.255.255.0 10.1.4.1  
[*DeviceB] ip route-static 10.1.3.0 255.255.255.0 10.1.4.6  
[*DeviceB] commit
```

Configure an IPv4 default route on Device C.

```
[~DeviceC] ip route-static 0.0.0.0 0.0.0.0 10.1.4.5  
[*DeviceC] commit
```

Step 3 Configure a default gateway for each host.

Configure the default gateways of PC1, PC2, and PC3 as 10.1.1.1, 10.1.2.1, and 10.1.3.1 respectively.

Step 4 Verify the configuration.

Check the IP routing table of Device A.

```
[~DeviceA] display ip routing-table  
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
```

Routing Table: Public						
Destinations : 12			Routes : 12			
Destination/Mask	Proto	Pre	Cost	Flags	NextHop	Interface
0.0.0.0/0	Static	60	0	RD	10.1.4.2	GigabitEthernet1/0/0
10.1.1.0/24	Direct	0	0	D	10.1.1.1	GigabitEthernet2/0/0
10.1.1.1/32	Direct	0	0	D	127.0.0.1	GigabitEthernet2/0/0
10.1.1.255/32	Direct	0	0	D	127.0.0.1	GigabitEthernet2/0/0
10.1.4.0/30	Direct	0	0	D	10.1.4.1	GigabitEthernet1/0/0
10.1.4.1/32	Direct	0	0	D	127.0.0.1	GigabitEthernet1/0/0
10.1.4.2/32	Direct	0	0	D	10.1.4.2	GigabitEthernet1/0/0
10.1.4.255/32	Direct	0	0	D	127.0.0.1	GigabitEthernet1/0/0
127.0.0.0/8	Direct	0	0	D	127.0.0.1	InLoopBack0
127.0.0.1/32	Direct	0	0	D	127.0.0.1	InLoopBack0
127.255.255.255/32	Direct	0	0	D	127.0.0.1	InLoopBack0
255.255.255.255/32	Direct	0	0	D	127.0.0.1	InLoopBack0

Run the **ping** command to verify the connectivity.

```
[~DeviceA] ping 10.1.3.1
PING 10.1.3.1: 56 data bytes, press CTRL_C to break
Reply from 10.1.3.1: bytes=56 Sequence=1 ttl=254 time=62 ms
Reply from 10.1.3.1: bytes=56 Sequence=2 ttl=254 time=63 ms
Reply from 10.1.3.1: bytes=56 Sequence=3 ttl=254 time=63 ms
Reply from 10.1.3.1: bytes=56 Sequence=4 ttl=254 time=62 ms
Reply from 10.1.3.1: bytes=56 Sequence=5 ttl=254 time=62 ms
--- 10.1.3.1 ping statistics ---
5 packet(s) transmitted
5 packet(s) received
0.00% packet loss
round-trip min/avg/max = 62/62/63 ms
```

Run the **tracert** command to verify the connectivity.

```
[~DeviceA] tracert 10.1.3.1
traceroute to 10.1.3.1(10.1.3.1), max hops: 30 ,packet length: 40
1 10.1.4.2 31 ms 32 ms 31 ms
2 10.1.4.6 62 ms 63 ms 62 ms
```

----End

Configuration Files

- Device A configuration file

```

Example for Configuring IPv4 Floating Static Routes

IPv4 Floating static routes can be used for the static route backup.

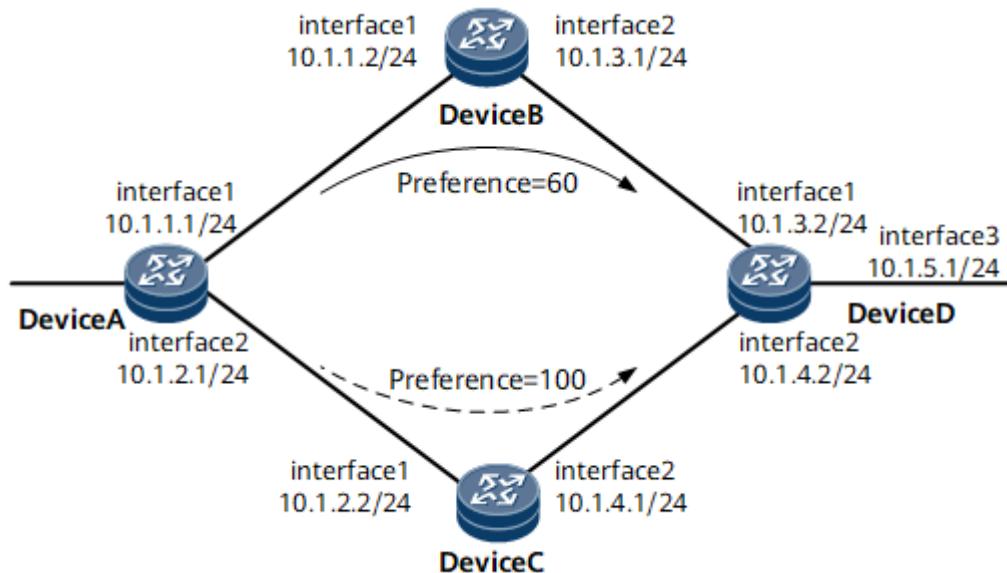

Networking Requirements

Figure 1-43 shows the IP addresses and masks of each router interface. Two IPv4 static routes to 10.1.5.0/24 are configured on Device A. The primary static route passes through Device B, and the floating static route passes through Device C.

Figure 1-43 Networking for configuring IPv4 floating static routes

Interfaces 1 through 3 in this example represent GE 1/0/1, GE 1/0/2, and GE 1/0/3, respectively.

Precautions

When configuring an IPv4 floating static route, a next-hop address of this route must be specified if the outbound interface is of the broadcast type.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure an IPv4 address for each interface of each router.
2. On Devices B and C, configure IPv4 static routes to 10.1.5.0/24.
3. On Device A, configure two IPv4 static routes to 10.1.5.0/24 with different priorities.
4. On Device D, configure IPv4 static routes to 10.1.1.0/24 and 10.1.2.0/24 so that routers can communicate.

Data Preparation

To complete the configuration, you need the following data:

- On Device A, priority values of two static routes (60 for the one with 10.1.1.2 as the next hop address and 100 for the one with 10.1.2.2 as the next-hop address)

Procedure

Step 1 Configure an IP address for each interface. For configuration details, see [Configuration File](#) in this section.

Step 2 Configure IPv4 static routes.

Configure IPv4 static routes on Device B.

```
[~DeviceB] ip route-static 10.1.5.0 24 10.1.3.2
[*DeviceB] commit
```

Configure IPv4 static routes on Device C.

```
[~DeviceC] ip route-static 10.1.5.0 24 10.1.4.2  
[*DeviceC] commit
```

Configure IPv4 static routes on Device A.

```
[*DeviceA] ip route-static 10.1.5.0 24 10.1.1.2  
[*DeviceA] ip route-static 10.1.5.0 24 10.1.2.2 preference 100  
[*DeviceA] commit
```

Configure IPv4 static routes on Device D.

```
[~DeviceD] ip route-static 10.1.1.0 24 10.1.3.1  
[*DeviceD] ip route-static 10.1.2.0 24 10.1.4.1  
[*DeviceD] commit
```

Step 3 Verify the configuration.

View information about static routes in the IP routing table of Device A.

```
<DeviceA> display ip routing-table protocol static  
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route  
-----  
_public_ Routing Table : Static  
  
Destinations : 1      Routes : 1      Configured Routes : 1  
Static routing table status : <Active>  
    Destinations : 1      Routes : 1  
  
Destination/Mask   Proto Pre Cost      Flags NextHop      Interface  
10.1.5.0/24  Static 60  0          RD 10.1.1.2      GigabitEthernet1/0/1  
  
Static routing table status : <Inactive>  
    Destinations : 0      Routes : 0
```

Use the **tracert** command to check the connectivity on Device A.

```
<DeviceA> tracert 10.1.5.1  
traceroute to 10.1.5.1(10.1.5.1), max hops: 30 ,packet length: 40  
1 10.1.1.2 90 ms 1 ms 1 ms  
2 10.1.5.1 4 ms 1 ms 2 ms
```

Run the **shutdown** command on GE 1/0/1 of Device A to simulate a link fault.

```
[~DeviceA] interface GigabitEthernet 1/0/1  
[~DeviceA-GigabitEthernet1/0/1] shutdown  
[*DeviceA-GigabitEthernet1/0/1] commit
```

View information about static routes in the IP routing table of Device A. The route to 10.1.5.0/24 switches to the floating static route with next hop 10.1.2.2.

```
[~DeviceA-GigabitEthernet1/0/1] quit  
[~DeviceA] quit  
<DeviceA> display ip routing-table protocol static  
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route  
-----  
_public_ Routing Table : Static  
  
Destinations : 1      Routes : 1      Configured Routes : 1  
Static routing table status : <Active>  
    Destinations : 1      Routes : 1  
  
Destination/Mask   Proto Pre Cost      Flags NextHop      Interface  
10.1.5.0/24  Static 100  0          RD 10.1.2.2      GigabitEthernet1/0/2  
  
Static routing table status : <Inactive>  
    Destinations : 0      Routes : 0
```

Use the **tracert** command to check the connectivity on Device A.

```
<DeviceA> tracert 10.1.5.1
traceroute to 10.1.5.1(10.1.5.1), max hops: 30 ,packet length: 40
1 10.1.2.2 100 ms 1 ms 1 ms
2 10.1.5.1 5 ms 1 ms 2 ms
```

----End

Example for Configuring Dynamic BFD for IPv4 Static Routes

Dynamic BFD for IPv4 static routes can fast detect link failures.

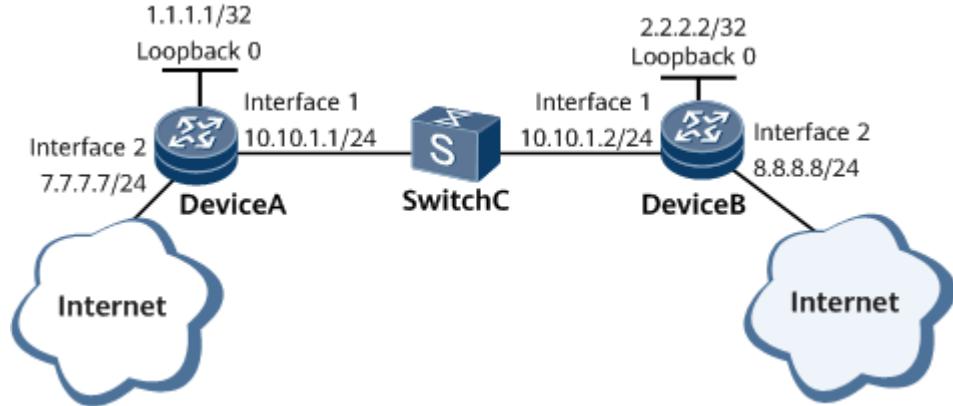

Networking Requirements

On the network shown in [Figure 1-44](#), DeviceA is connected to DeviceB through SwitchC. It is required that DeviceA communicate with other Devices through static default routes and that a BFD session be established between DeviceA and DeviceB to detect link failures.

Figure 1-44 Configuring BFD for static routes

 NOTE

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

Precautions

When configuring dynamic BFD for static routes, note the following:

- BFD has been enabled globally.
- The parameters configured on the two ends of a BFD session must be consistent.

Configuration Roadmap

The configuration roadmap is as follows:

1. On DeviceA, configure an IPv4 static route to DeviceB.
2. Configure dynamic BFD for static routes.

Data Preparation

To complete the configuration, you need the following data:

- Peer IP address to be detected by BFD
- Default values of the local detection multiplier and of the minimum intervals at which BFD Control packets are sent and received

Procedure

Step 1 Configure an IP address for each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure static routes.

On DeviceA, configure a static route to 2.2.2.2/32.

```
[~DeviceA] ip route-static 2.2.2.2 32 10.10.1.2  
[*DeviceA] commit
```

Check the IP routing table of DeviceA. The following command output shows that the static route exists in the routing table.

```
[~DeviceA] display ip routing-table  
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route  
-----  
Routing Table : _public_  
Destinations : 10      Routes : 10  
  
Destination/Mask Proto Pre Cost     Flags NextHop       Interface  
1.1.1.1/32 Direct 0   0          D 127.0.0.1    LoopBack0  
2.2.2.2/32 Static 60  0          RD 10.10.1.2  GigabitEthernet1/0/0  
127.0.0.0/8 Direct 0   0          D 127.0.0.1    InLoopBack0  
127.0.0.1/32 Direct 0   0          D 127.0.0.1    InLoopBack0  
127.255.255.255/32 Direct 0  0          D 127.0.0.1    InLoopBack0  
255.255.255.255/32 Direct 0  0          D 127.0.0.1    InLoopBack0  
10.10.1.0/24 Direct 0   0          D 10.10.1.1   GigabitEthernet1/0/0  
10.10.1.1/32 Direct 0   0          D 127.0.0.1   GigabitEthernet1/0/0  
10.10.1.2/32 Direct 0   0          D 10.10.1.2   GigabitEthernet1/0/0  
10.10.1.255/32 Direct 0  0          D 127.0.0.1   GigabitEthernet1/0/0
```

On DeviceB, configure a static route to 1.1.1.1/32.

```
[~DeviceB] ip route-static 1.1.1.1 32 10.10.1.1  
[*DeviceB] commit
```

Step 3 Configure dynamic BFD for static routes.

On DeviceA, bind the static route to the BFD session.

```
[~DeviceA] bfd  
[*DeviceA-bfd] quit  
[*DeviceA] ip route-static bfd 10.10.1.2 local-address 10.10.1.1  
[*DeviceA] ip route-static 2.2.2.2 32 10.10.1.2 bfd enable  
[*DeviceA] commit
```

On DeviceB, bind the static route to the BFD session.

```
[~DeviceB] bfd  
[*DeviceB-bfd] quit  
[*DeviceB] ip route-static bfd 10.10.1.1 local-address 10.10.1.2  
[*DeviceB] ip route-static 1.1.1.1 32 10.10.1.1 bfd enable  
[*DeviceB] commit
```

Step 4 Verify the configuration.

After the preceding configuration, on DeviceA and DeviceB, you can view that the BFD session has been established and is Up and that the static routes have been bound to the BFD session.

Use the command output DeviceA as an example.

```
[~DeviceA] display bfd session all verbose
(w): State in WTR
(*): State is invalid

return
```

Example for Configuring Static BFD for IPv4 Static Routes

To improve network reliability, you can configure static BFD for IPv4 static routes to fast detect link failures and speed up route convergence.

Networking Requirements

On the network shown in [Figure 1-45](#), DeviceA is connected to DeviceB through Switch C. It is required that DeviceA communicate with other devices through static default routes and that a BFD session be set up between DeviceA and DeviceB to detect link faults.

Figure 1-45 Configuring static BFD for IPv4 static routes

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure a BFD session between DeviceA and DeviceB to detect the link between the two devices.
2. Configure a default static route from DeviceA to the external network and bind the default static route to the BFD session.

Data Preparation

To complete the configuration, you need the following data:

- Peer IP address to be detected by BFD
- Local discriminator and remote discriminator of a BFD session
- Default values of the local detection multiplier and of the minimum intervals at which BFD Control packets are sent and received

Procedure

Step 1 Configure an IP address for each interface.

For configuration details, see "Configuration Files" in this section.

Step 2 Configure a BFD session between DeviceA and DeviceB.

On DeviceA, configure a BFD session between DeviceA and DeviceB.

```
<DeviceA> system-view
[~DeviceA] bfd
[*DeviceA-bfd] quit
[*DeviceA] bfd aa bind peer-ip 1.1.1.2
[*DeviceA-bfd-session-aa] discriminator local 10
[*DeviceA-bfd-session-aa] discriminator remote 20
[*DeviceA-bfd-session-aa] commit
[~DeviceA-bfd-session-aa] quit
```

On DeviceB, configure a BFD session between DeviceA and DeviceB.

```
<DeviceB> system-view
[~DeviceB] bfd
[*DeviceB-bfd] quit
[*DeviceB] bfd bb bind peer-ip 1.1.1.1
[*DeviceB-bfd-session-bb] discriminator local 20
[*DeviceB-bfd-session-bb] discriminator remote 10
[*DeviceB-bfd-session-bb] commit
[~DeviceB-bfd-session-bb] quit
```

Step 3 Configure a default static route and bind it to a BFD session.

On DeviceA, configure a default static route to the external network and bind it to BFD session named **aa**.

```
[~DeviceA] ip route-static 0.0.0.0 0 1.1.1.2 track bfd-session aa
```

Step 4 Verify the configuration.

Run the **display bfd session all** command on DeviceA and DeviceB. The command output shows that a BFD session has been established and is up. Then, run the **display current-configuration | include bfd** command in the system view. The command output shows that the static route has been bound to the BFD session.

Use the command output on DeviceA as an example.

```
[~DeviceA] display bfd session all
-----
Local  Remote PeerIpAddr   State    Type      InterfaceName
-----
10    20    1.1.1.2        Up      S_IP_PEER  -
-----
Total UP/DOWN Session Number : 1/0
[~DeviceA] display current-configuration | include bfd
```

```
bfd
bfd aa bind peer-ip 1.1.1.2
ip route-static 0.0.0.0 0.0.0.0 1.1.1.2 track bfd-session aa
```

Check the IP routing table of DeviceA. The command output shows that the static route exists in the routing table.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table: Public
Destinations : 5      Routes : 5
Destination/Mask Proto Pre Cost   Flags NextHop     Interface
0.0.0.0/0    Static 60 0        RD 1.1.1.2      GigabitEthernet1/0/0
1.1.1.0/24   Direct 0 0        D  1.1.1.1      GigabitEthernet1/0/0
1.1.1.1/32   Direct 0 0        D  127.0.0.1    GigabitEthernet1/0/0
1.1.1.255/32 Direct 0 0        D  127.0.0.1    GigabitEthernet1/0/0
255.255.255.255/32 Direct 0 0        D  127.0.0.1    InLoopBack0
```

Run the **shutdown** command on GE 1/0/0 of DeviceB to simulate a link fault.

```
[~DeviceB] interface GigabitEthernet 1/0/0
[~DeviceB-GigabitEthernet1/0/0] shutdown
```

Check the IP routing table of DeviceA. The command output shows that the static default route 0.0.0.0/0 does not exist. This is because the default static route has become unavailable after the BFD session bound to the route detects the link fault.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table: Public
Destinations : 4      Routes : 4
Destination/Mask Proto Pre Cost   Flags NextHop     Interface
1.1.1.0/24   Direct 0 0        D  1.1.1.1      GigabitEthernet1/0/0
1.1.1.1/32   Direct 0 0        D  127.0.0.1    GigabitEthernet1/0/0
1.1.1.255/32 Direct 0 0        D  127.0.0.1    GigabitEthernet1/0/0
255.255.255.255/32 Direct 0 0        D  127.0.0.1    InLoopBack0
```

----End

```

Example for Configuring NQA for IPv4 Static Routes

NQA for IPv4 static routes can fast detect network faults and control the advertisement of static routes.

Networking Requirements

On a simple network or when the router cannot use a dynamic routing protocol to generate routes, you can configure static routes. Unlike dynamic routing protocols, static routes do not have a detection mechanism. If a link fails, a network administrator must manually delete the corresponding static route from the IP routing table, which delays link switchovers and causes a lengthy service interruption.

Bidirectional Forwarding Detection (BFD) for static routes is adaptable to link changes but requires that both ends of a link support BFD. If either end of a link does not support BFD, configure NQA for IPv4 static routes. If an NQA test instance detects a link fault, it instructs the routing management module to delete the associated static route from the IPv4 routing table. Then traffic is switched to a backup route to prevent lengthy service interruptions.

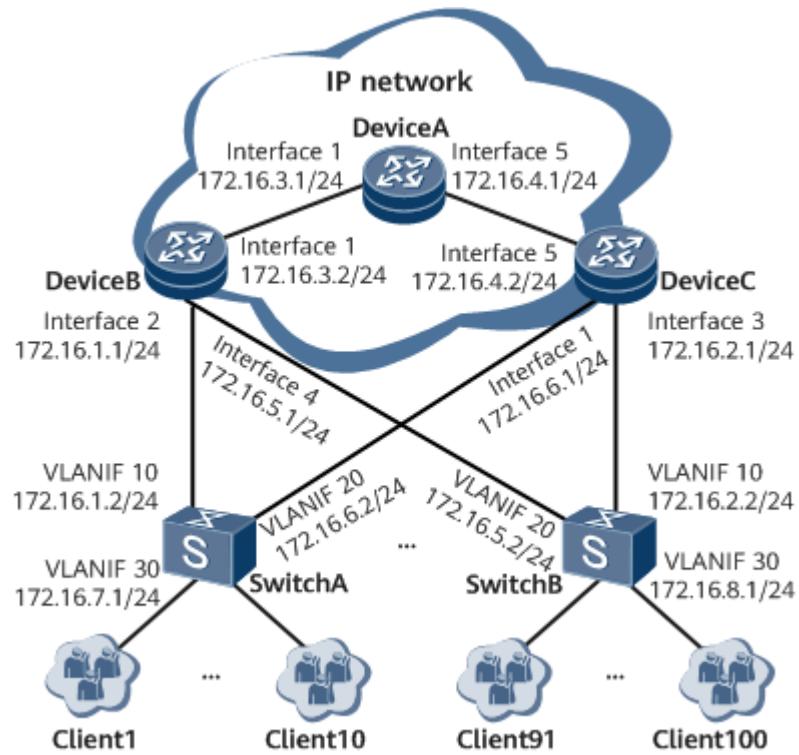

In [Figure 1-46](#), backup links are deployed on the IP metropolitan area network (MAN).

- Static routes are configured on DeviceB and DeviceC. DeviceB is the active device, while DeviceC is the standby device.
- In most cases, traffic is transmitted over the primary link (DeviceB -> SwitchA).
- If the primary link fails, traffic switches to the backup link (DeviceC -> SwitchA).

Figure 1-46 NQA for IPv4 static routes

NOTE

Interfaces 1 through 5 in this example represent GE 1/0/0, GE 1/0/1, GE 1/0/2, GE 1/0/3, and GE 2/0/3, respectively.

NOTE

In this example, switches A and B are used for user access. In actual networking, users can also access the network through the OLT, DSLAM, MSAN, or xDSL. The configurations on DeviceA, DeviceB, and DeviceC are the same.

Configuration Roadmap

The configuration roadmap is as follows:

1. Create an Internet Control Message Protocol (ICMP) NQA test instance to monitor the status of the primary link.
Create an ICMP NQA test instance on the NQA client DeviceB to test whether the primary link is running properly.
2. Configure static routes and associate the static route along the primary link with the ICMP NQA test instance.
Configure static routes on DeviceB and DeviceC, and associate the static route configured on DeviceB with the ICMP NQA test instance. If the ICMP NQA test instance detects a link fault, it instructs the routing management module to delete the associated static route from the IPv4 routing table.
3. Configure a dynamic routing protocol.
Configure a dynamic routing protocol on DeviceA, DeviceB, and DeviceC so that they can learn routes from one another.
4. Configure OSPF to import static routes and set a smaller cost for the static route along the primary link than for the one along the backup link.
Configure OSPF on DeviceB and DeviceC to import static routes, and set a higher cost for the static route imported by DeviceC than for the one

imported by DeviceB. This configuration allows DeviceA to preferentially select the link (DeviceB -> SwitchA).

Data Preparation

To complete the configuration, you need the following data:

- IP address of each interface
- NQA item values (for details, see [Table 1-11](#))

Table 1-11 NQA item values

Item	Value
Administrator name	user
Name of the test instance	test
Test type	ICMP
Destination address	172.16.1.2
Interval at which the NQA test automatically runs	10 seconds
Number of probes	2
Interval at which probe packets are sent	5 seconds
Timeout period	4 seconds

- OSPF backbone area (Area 0) of DeviceA, DeviceB, and DeviceC, and their router IDs (1.1.1.1, 2.2.2.2, and 3.3.3.3)

Procedure

Step 1 Configure interface IPv4 addresses. For configuration details, see [Configuration Files](#) in this section.

Step 2 Create an NQA test instance on DeviceB to test the link between DeviceB and SwitchA.

```
<DeviceB> system-view
[~DeviceB] nqa test-instance user test
[*DeviceB-nqa-user-test] test-type icmp
[*DeviceB-nqa-user-test] destination-address ipv4 172.16.1.2
[*DeviceB-nqa-user-test] frequency 10
[*DeviceB-nqa-user-test] probe-count 2
[*DeviceB-nqa-user-test] interval seconds 5
[*DeviceB-nqa-user-test] timeout 4
[*DeviceB-nqa-user-test] start now
[*DeviceB-nqa-user-test] commit
[~DeviceB-nqa-user-test] quit
```

Step 3 Configure IPv4 static routes.

```
# Configure an IPv4 static route on DeviceB and associate it with the NQA test instance.
```

```
[~DeviceB] ip route-static 172.16.7.0 255.255.255.0 GigabitEthernet 1/0/1 172.16.1.2 track nqa user test  
[*DeviceB] commit
```

Configure an IPv4 static route on DeviceC.

```
[~DeviceC] ip route-static 172.16.7.0 255.255.255.0 GigabitEthernet 1/0/0 172.16.6.2  
[*DeviceC] commit
```

Step 4 Configure a dynamic routing protocol on DeviceA, DeviceB, and DeviceC. OSPF is used in this example.

Configure OSPF on DeviceA.

```
[~DeviceA] ospf 1  
[*DeviceA-ospf-1] area 0.0.0.0  
[*DeviceA-ospf-1-area-0.0.0.0] network 172.16.3.0 0.0.0.255  
[*DeviceA-ospf-1-area-0.0.0.0] network 172.16.4.0 0.0.0.255  
[*DeviceA-ospf-1-area-0.0.0.0] quit  
[*DeviceA-ospf-1] quit  
[*DeviceA] commit
```

Configure OSPF on DeviceB.

```
[~DeviceB] ospf 1  
[*DeviceB-ospf-1] area 0.0.0.0  
[*DeviceB-ospf-1-area-0.0.0.0] network 172.16.3.0 0.0.0.255  
[*DeviceB-ospf-1-area-0.0.0.0] quit  
[*DeviceB-ospf-1] quit  
[*DeviceB] commit
```

Configure OSPF on DeviceC.

```
[~DeviceC] ospf 1  
[*DeviceC-ospf-1] area 0.0.0.0  
[*DeviceC-ospf-1-area-0.0.0.0] network 172.16.4.0 0.0.0.255  
[*DeviceC-ospf-1-area-0.0.0.0] quit  
[*DeviceC-ospf-1] quit  
[*DeviceC] commit
```

Step 5 Configure OSPF on DeviceB and DeviceC to import static routes.

Configure OSPF on DeviceB to import a static route, and set the cost to 10 for the static route.

```
[~DeviceB] ospf 1  
[*DeviceB-ospf-1] import-route static cost 10  
[*DeviceB-ospf-1] commit  
[*DeviceB-ospf-1] quit
```

Configure OSPF on DeviceC to import a static route, and set the cost to 20 for the static route.

```
[~DeviceC] ospf 1  
[*DeviceC-ospf-1] import-route static cost 20  
[*DeviceC-ospf-1] commit  
[*DeviceC-ospf-1] quit
```

Step 6 Verify the configuration.

After the configuration is complete, run the **display current-configuration | include nqa** command on DeviceB in the system view. The command output shows that the IPv4 static route has been associated with the NQA test instance. Run the **display nqa results** command. The command output shows that an NQA test instance has been created.

Display configurations of NQA for IPv4 static routes.

```
[~DeviceB] display current-configuration | include nqa
```

```
ip route-static 172.16.7.0 255.255.255.0 GigabitEthernet 1/0/1 172.16.1.2 track nqa user test  
nqa test-instance user test
```

Display NQA test results.

```
[~DeviceB] display nqa results test-instance user test  
NQA entry(user, test) : testflag is active ,testtype is icmp  
1 . Test 6645 result The test is finished  
Send operation times: 2 Receive response times: 2  
Completion:success RTD OverThresholds number:0  
Attempts number:1 Drop operation number:0  
Disconnect operation number:0 Operation timeout number:0  
System busy operation number:0 Connection fail number:0  
Operation sequence errors number:0 RTT Stats errors number:0  
Destination ip address:172.16.1.2

```

The static route has been associated with the NQA test instance on DeviceB. If NQA detects a link fault, it rapidly notifies DeviceB that the associated static route is unavailable. DeviceA cannot learn the route to 172.16.7.0/24 from DeviceB. However, DeviceA can learn the route to 172.16.7.0/24 from DeviceC. The route's next hop address is 172.16.4.2, and the cost is 20. Traffic switches to the link DeviceC -> SwitchA.

Example for Configuring NQA Group for IPv4 Static Route

NQA group for IPv4 static route allows an NQA group to be associated with multiple NQA test instances to monitor multiple links, rapidly detect network faults, and control advertisement of IPv4 static routes, thereby implementing service switching.

Networking Requirements

NQA group for IPv4 static route monitors the link status of an IPv4 static route through association between the static route and an NQA group that consists of multiple NQA test instances. The RM module determines whether the static route is active based on the test result of the NQA group. If the IPv4 static route is inactive, the RM module deletes it from the IP routing table and selects an available backup link for data forwarding, which prevents lengthy service interruptions.

[Figure 1-47](#) shows a network with redundant links.

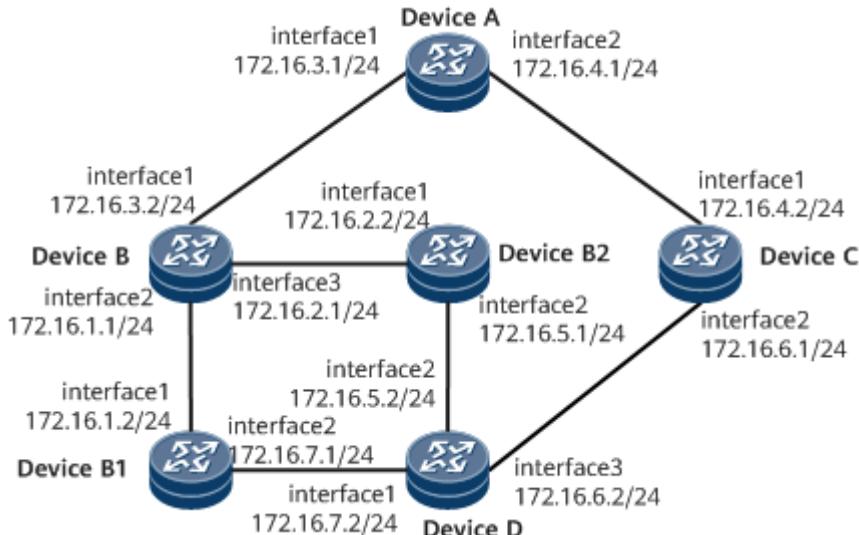

- BGP peer relationships are established between Device A and Device B and between Device A and Device C.

- On Device B and Device C, default static routes are configured and imported into BGP, and different PrefVal values are configured so that Device B and Device C function as the master device and backup device, respectively.
- Device B and Device D are connected through two links by way of Device B1 and Device B2.
- In normal cases, traffic is transmitted along the primary link (Device B -> Device D).
- If the primary link fails (the NQA group bound to the default route of Device B considers the IPv4 static route inactive when monitoring the two links from Device B to Device D), traffic is switched to the backup link (Device C -> Device D).

Figure 1-47 Network diagram of NQA group for IPv4 static route

 NOTE

In this example, interface1, interface2, and interface3 represent GE 1/0/0, GE 1/0/1, and GE 1/0/2, respectively.

Configuration Roadmap

The configuration roadmap is as follows:

1. Create NQA test instances of the ICMP type to detect faults on the primary link.
Create two NQA test instances of the ICMP type between Device B and Device B1 and between Device B and Device B2 to correspond to the two links between Device B and Device D and to check whether the primary link (Device B -> Device D) is running properly.
2. Create an NQA group.
Bind the two NQA test instances of the ICMP type to the NQA group.
3. Configure static routes and associate the static route along the primary link with the NQA group.
Configure IPv4 static routes to loopback0 interfaces between Device A and Device B, and between Device A and Device C. Configure default IPv4 static

routes on Device B and Device C. Associate the IPv4 static route configured on Device B with the NQA group, which collects the detection results of two NQA test instances to determine its status. When the NQA group goes down, the device determines that the current link is faulty and instructs the RM module to delete the IPv4 static route from the IP routing table.

4. Configure BGP.

Configure BGP on Device A, Device B, and Device C so that they can learn routes from each other.

5. Configure BGP to import IPv4 static routes and set a larger PrefVal value for the primary link.

Configure BGP on Device B and Device C to import IPv4 static routes, and set a larger PrefVal value for the IPv4 static route imported by Device B. When Device A learns routes to the same destination from Device B and Device C, it preferentially selects the link (Device B -> Device D), which has a larger PrefVal value.

Data Preparation

To complete the configuration, you need the following data:

- IP address of each interface
- NQA-related configurations (for details, see [Table 1-12](#))

Table 1-12 NQA parameter values

Item	Value
Administrator name	user1, user2
Test instance name	test1, test2
Test type	ICMP
Destination address	172.16.1.2, 172.16.2.2
Test interval	10s
Number of probes	2
Interval at which packets are sent	5s
Timeout period	4s

- Operation type between test instances in the NQA group: OR
- BGP AS numbers (the same) and router IDs of Device A, Device B, and Device C (1.1.1.1, 2.2.2.2, and 3.3.3.3, respectively)

Procedure

Step 1 Configure IP addresses. For details, see [Configuration Files](#).

Step 2 On Device B, configure two NQA test instances of the ICMP type between Device B and Device B1 and between Device B and Device B2.

```
<DeviceB> system-view
[~DeviceB] nqa test-instance user1 test1
[*DeviceB-nqa-user1-test1] test-type icmp
[*DeviceB-nqa-user1-test1] destination-address ipv4 172.16.1.2
[*DeviceB-nqa-user1-test1] frequency 10
[*DeviceB-nqa-user1-test1] probe-count 2
[*DeviceB-nqa-user1-test1] interval seconds 5
[*DeviceB-nqa-user1-test1] timeout 4
[*DeviceB-nqa-user1-test1] start now
[*DeviceB-nqa-user1-test1] commit
[~DeviceB-nqa-user1-test1] quit
[~DeviceB] nqa test-instance user2 test2
[*DeviceB-nqa-user2-test2] test-type icmp
[*DeviceB-nqa-user1-test1] destination-address ipv4 172.16.2.2
[*DeviceB-nqa-user2-test2] frequency 10
[*DeviceB-nqa-user2-test2] probe-count 2
[*DeviceB-nqa-user2-test2] interval seconds 5
[*DeviceB-nqa-user2-test2] timeout 4
[*DeviceB-nqa-user2-test2] start now
[*DeviceB-nqa-user2-test2] commit
[~DeviceB-nqa-user2-test2] quit
```

Step 3 Create an NQA group and bind the two NQA test instances of the ICMP type to the group.

```
[~DeviceB] nqa group group1
[*DeviceB-nqa-group-group1] nqa test-instance user1 test1
[*DeviceB-nqa-group-group1] nqa test-instance user2 test2
[*DeviceB-nqa-group-group1] operator or
[*DeviceB-nqa-group-group1] commit
[~DeviceB-nqa-group-group1] quit
```

Step 4 Configure static routes.

Configure static routes to loopback interfaces between Device A and Device B, and between Device A and Device C.

```
[~DeviceA] ip route-static 2.2.2.2 255.255.255.255 GigabitEthernet 1/0/0 172.16.3.2
[~DeviceA] ip route-static 3.3.3.3 255.255.255.255 GigabitEthernet 1/0/1 172.16.4.2
[*DeviceA] commit
```

Configure a static route to the loopback interface of Device A on Device B.

```
[~DeviceB] ip route-static 1.1.1.1 255.255.255.255 GigabitEthernet 1/0/0 172.16.3.1
[*DeviceB] commit
```

Configure a static route to the loopback interface of Device A on Device C.

```
[~DeviceC] ip route-static 1.1.1.1 255.255.255.255 GigabitEthernet 1/0/1 172.16.4.1
[*DeviceC] commit
```

Configure a default static route on Device B and associate it with the NQA group.

```
[*DeviceB] ip route-static 0.0.0.0 32 NULL0 track nqa-group group1
[*DeviceB] commit
```

Configure a default static route on Device C.

```
[*DeviceC] ip route-static 0.0.0.0 32 NULL0
[*DeviceC] commit
```

Step 5 Configure BGP on Device A, Device B, and Device C.

Configure BGP on Device A.

```
[~DeviceA] bgp 100
[*DeviceA-bgp] peer 2.2.2.2 as-number 100
[*DeviceA-bgp] peer 2.2.2.2 connect-interface Loopback0
```

```
[*DeviceA-bgp] peer 3.3.3.3 as-number 100
[*DeviceA-bgp] peer 3.3.3.3 connect-interface Loopback0
[*DeviceA-bgp] quit
[*DeviceA] commit
```

Configure BGP on Device B.

```
[~DeviceB] bgp 100
[*DeviceB-bgp] peer 1.1.1.1 as-number 100
[*DeviceB-bgp] peer 1.1.1.1 connect-interface Loopback0
[*DeviceB-bgp] quit
[*DeviceB] commit
```

Configure BGP on Device C.

```
[~DeviceC] bgp 100
[*DeviceC-bgp] peer 1.1.1.1 as-number 100
[*DeviceC-bgp] peer 1.1.1.1 connect-interface Loopback0
[*DeviceC-bgp] quit
[*DeviceC] commit
```

Step 6 Configure BGP on Device B and Device C to import IPv4 static routes, and set a larger PrefVal value for the primary link.

Configure BGP on Device B to import IPv4 static routes, and set the PrefVal value to 200.

```
[~DeviceB] bgp 100
[*DeviceB-bgp] import-route static
[*DeviceB-bgp] ipv4-family unicast
[*DeviceB-bgp-af-ipv4] peer 1.1.1.1 preferred-value 200
[*DeviceB-bgp-af-ipv4] commit
[*DeviceB-bgp-af-ipv4] quit
[*DeviceB-bgp] quit
```

Configure BGP on Device C to import IPv4 static routes, and set the PrefVal value to 100.

```
[~DeviceC] bgp 100
[*DeviceC-bgp] import-route static
[*DeviceC-bgp] ipv4-family unicast
[*DeviceC-bgp-af-ipv4] peer 1.1.1.1 preferred-value 100
[*DeviceC-bgp-af-ipv4] commit
[*DeviceC-bgp-af-ipv4] quit
[*DeviceC-bgp] quit
```

Step 7 Verify the configuration.

Check the results of the two NQA test instances on Device B.

```
[~DeviceB] display nqa results test-instance user1 test1
NQA entry(user1, test1) :testflag is inactive ,testtype is icmp
1 . Test 1 result  The test is finished
Send operation times: 3          Receive response times: 3
Completion:success           RTD OverThresholds number:0
Attempts number:1            Drop operation number:0
Disconnect operation number:0    Operation timeout number:0
System busy operation number:0   Connection fail number:0
Operation sequence errors number:0   RTT Status errors number:0
Destination ip address:172.16.1.2
Min/Max/Average Completion Time: 11/185/69
Sum/Square-Sum Completion Time: 207/34467
Last Good Probe Time: 2022-09-24 15:08:38.6
Lost packet ratio: 0 %

[~DeviceB] display nqa results test-instance user2 test2
NQA entry(user2, test2) :testflag is inactive ,testtype is icmp
1 . Test 1 result  The test is finished
Send operation times: 3          Receive response times: 3
Completion:success           RTD OverThresholds number:0
```

```
Attempts number:1          Drop operation number:0
Disconnect operation number:0   Operation timeout number:0
System busy operation number:0   Connection fail number:0
Operation sequence errors number:0   RTT Status errors number:0
Destination ip address:172.16.2.2
Min/Max/Average Completion Time: 9/16/11
Sum/Square-Sum Completion Time: 34/418
Last Good Probe Time: 2022-09-24 15:08:50.3
Lost packet ratio: 0 %
```

The command output shows "Lost packet ratio 0 %," indicating that the link is running properly.

Check the test result of the NQA group on Device B.

```
[~DeviceB] display nqa group
NQA-group information:
-----
NQA-group group1
Status: UP      Operator: OR
-----
Admin-name           Test-name       Status
-----
user1               test1          UP
user2               test2          UP
```

Check the routing table of Device A.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Destinations : 14      Routes : 14
-----

172.16.3.0/24     Direct 0  0        D   172.16.3.1       GigabitEthernet1/0/0
172.16.3.1/32     Direct 0  0        D   127.0.0.1       GigabitEthernet1/0/0
172.16.3.255/32   Direct 0  0        D   127.0.0.1       GigabitEthernet1/0/0
172.16.4.0/24     Direct 0  0        D   172.16.4.1       GigabitEthernet1/0/1
172.16.4.1/32     Direct 0  0        D   127.0.0.1       GigabitEthernet1/0/1
172.16.4.255/32   Direct 0  0        D   127.0.0.1       GigabitEthernet1/0/1
255.255.255.255/32 Direct 0  0        D   127.0.0.1       InLoopBack0
```

The command output shows that the next hop used to forward user traffic on Device A is Device B, indicating that user traffic is transmitted along the primary link.

Shut down GigabitEthernet 1/0/1 on Device B to simulate a link fault.

```
[~DeviceB] interface GigabitEthernet 1/0/1
[~DeviceB-GigabitEthernet1/0/1] shutdown
[~DeviceB-GigabitEthernet1/0/1] commit
[~DeviceB] quit
```

Check the NQA test result.

```
[~DeviceB] display nqa results test-instance user1 test1
NQA entry(user1, test1) :testflag is inactive ,testtype is icmp
2 . Test 2 result  The test is finished
Send operation times: 3          Receive response times: 0
Completion:failed          RTD OverThresholds number:0
```

```
Attempts number:1          Drop operation number:0
Disconnect operation number:0   Operation timeout number:3
System busy operation number:0   Connection fail number:0
Operation sequence errors number:0   RTT Status errors number:0
Destination ip address:172.16.1.2
Min/Max/Average Completion Time: 0/0/0
Sum/Square-Sum Completion Time: 0/0
Last Good Probe Time: 0000-00-00 00:00:00.0
Lost packet ratio: 100 %
```

"Completion:failed" and "Lost packet ratio: 100%" are displayed, indicating that the link where GigabitEthernet 1/0/1 resides is faulty.

Check the test result of the NQA group on Device B.

```
[~DeviceB] display nqa group
NQA-group information:
-----
NQA-group group1
Status: UP      Operator: OR
-----
Admin-name           Test-name        Status
-----
user1               test1           DOWN
user2               test2           UP
```

The operation type between test instances in the NQA group is OR. Therefore, the status of the NQA group remains UP.

Check the routing table of Device A.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Destinations : 14      Routes : 14
-----

172.16.3.0/24   Direct 0 0        D 172.16.3.1         GigabitEthernet1/0/0
172.16.3.1/32   Direct 0 0        D 127.0.0.1         GigabitEthernet1/0/0
172.16.3.255/32 Direct 0 0       D 127.0.0.1         GigabitEthernet1/0/0
172.16.4.0/24   Direct 0 0        D 172.16.4.1         GigabitEthernet1/0/1
172.16.4.1/32   Direct 0 0        D 127.0.0.1         GigabitEthernet1/0/1
172.16.4.255/32 Direct 0 0       D 127.0.0.1         GigabitEthernet1/0/1
255.255.255.255/32 Direct 0 0       D 127.0.0.1         InLoopBack0
```

The command output shows that the next hop used to forward user traffic on Device A changes to Device C, indicating that the traffic is switched to the backup link.

The NQA group on Device B is associated with the IPv4 static route. When the NQA group detects that both links from Device B to Device D fail, the NQA group goes down and rapidly notifies Device B that the associated IPv4 static route is unavailable. Service traffic is then switched to the backup link.

----End

Example for Associating EFM with IPv4 Static Routes

After EFM is associated with IPv4 static routes, the system responds to EFM Up/Down events on a specified interface and determines whether to activate static routes. In this manner, route advertisement is controlled and remote traffic is forwarded.

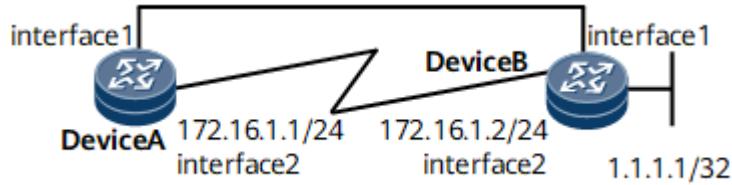

Networking Requirements

As shown in [Figure 1-48](#), DeviceA and DeviceB are connected and are enabled with EFM OAM. In addition, a static route destined for 1.1.1.1/32 is configured on DeviceA and associated with EFM.

Figure 1-48 Associating EFM with IPv4 static routes

In this example, interface1 and interface2 represent GE1/0/0 and GE1/0/1, respectively.

Configuration Roadmap

The configuration roadmap is as follows:

1. Enable EFM OAM both globally and on the interfaces of Device A and Device B.
2. Configure a static route destined for 1.1.1.1/32 on Device A and associate EFM with this static route.

Data Preparation

To complete the configuration, you need the IP addresses of interfaces.

Procedure

Step 1 Configure an IP address for each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Enable EFM OAM both globally and on the interfaces of Device A and Device B.

Enable EFM OAM both globally and on the interface of Device A.

```
<DeviceA> system-view
[~DeviceA] efm enable
[*DeviceA] interface GigabitEthernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] undo shutdown
[*DeviceA-GigabitEthernet1/0/0] efm enable
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
[~DeviceA] quit
```

Enable EFM OAM both globally and on the interface of Device B.

```
<DeviceB> system-view
[~DeviceB] efm enable
[*DeviceB] interface GigabitEthernet 1/0/0
[*DeviceB-GigabitEthernet1/0/0] undo shutdown
[*DeviceB-GigabitEthernet1/0/0] efm enable
[*DeviceB-GigabitEthernet1/0/0] commit
[~DeviceB-GigabitEthernet1/0/0] quit
[~DeviceB] quit
```

Display EFM OAM session information on Device A.

```
<DeviceA> display efm session all
Interface          EFM State        Loopback Timeout
-----  
GigabitEthernet1/0/0    detect           --
```

The preceding command output shows that the EFM OAM status is **detect**.

Step 3 Associating EFM with IPv4 static routes.

Configure a static route destined for 1.1.1.1/32 on Device A and associate EFM with this static route.

```
<DeviceA> system-view
[~DeviceA] ip route-static 1.1.1.1 255.255.255.255 GigabitEthernet1/0/1 172.16.1.2 track efm-state
GigabitEthernet1/0/0
[*DeviceA] commit
[~DeviceA] quit
```

Step 4 Verify the configuration.

Run the **display current-configuration | include efm** command on Device A. The following command output shows that the static route has been associated with EFM:

```
<DeviceA> display current-configuration | include efm
efm enable
ip route-static 1.1.1.1 255.255.255.255 GigabitEthernet1/0/1 172.16.1.2 track efm-state GigabitEthernet1/0/0
```

Display the IP routing table on Device A. The following command output shows that the static route destined for 1.1.1.1/32 exists in the IP routing table:

```
<DeviceA> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Destinations : 8      Routes : 8
Destination/Mask   Proto  Pre  Cost      Flags NextHop       Interface
1.1.1.1/32  Static  60   0        D  172.16.1.2    GigabitEthernet1/0/1
127.0.0.0/8   Direct  0   0        D  127.0.0.1    InLoopBack0
127.0.0.1/32  Direct  0   0        D  127.0.0.1    InLoopBack0
127.255.255.255/32 Direct  0   0        D  127.0.0.1    InLoopBack0
172.16.1.0/24  Direct  0   0        D  172.16.1.1    GigabitEthernet1/0/1
172.16.1.1/32  Direct  0   0        D  127.0.0.1    GigabitEthernet1/0/1
172.16.1.255/32 Direct  0   0        D  127.0.0.1    GigabitEthernet1/0/1
255.255.255.255/32 Direct  0   0        D  127.0.0.1    InLoopBack0
```

Run the **shutdown** command on GE 1/0/0 of Device A to check whether the EFM OAM status changes.

```
<DeviceA> system-view
[~DeviceA] interface GigabitEthernet 1/0/0
[~DeviceA-GigabitEthernet1/0/0] shutdown
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
[~DeviceA] quit
```

Run the **display efm session all** command on Device A. The following command output shows that the EFM OAM status changes to **discovery**:

```
<DeviceA> display efm session all
Interface          EFM State        Loopback Timeout
-----
```

Interface	EFM State	Loopback Timeout
GigabitEthernet1/0/0	discovery	--

Display the IP routing table on Device A. The command output shows that the static route destined for 1.1.1.1/32 does not exist. The static route is unavailable because it has been associated with EFM and the EFM session has not been established.

```
<DeviceA> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
```

Routing Table : _public_						
Destinations : 7			Routes : 7

Example for Configuring FRR for IPv4 Static Routes on the Public Network

FRR for IPv4 static routes on the public network can fast detect link failures.

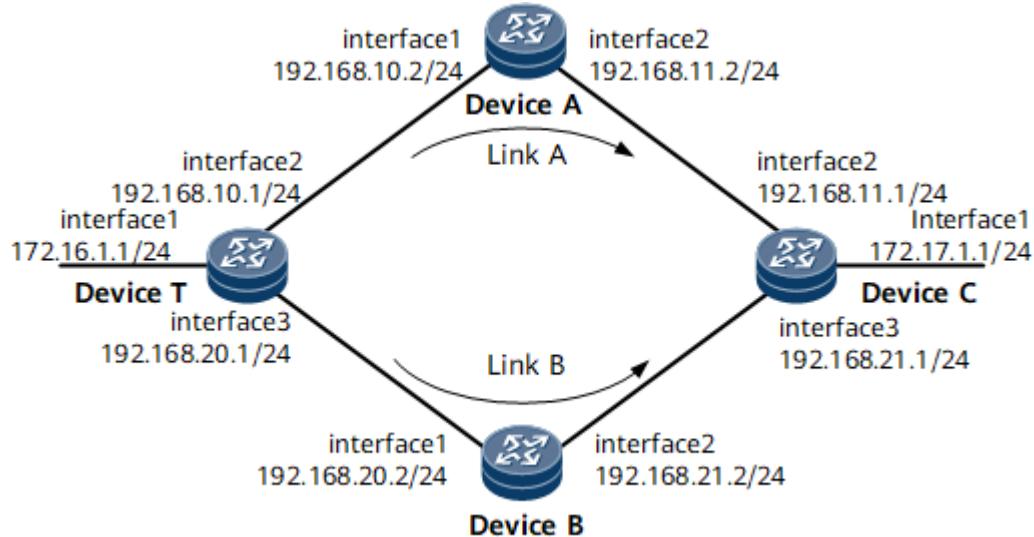

Networking Requirements

On the network shown in [Figure 1-49](#), it is required that two IPv4 static routes with Device A and Device B as the next hops be configured on Device T and that Link B function as the backup of Link A. If Link A fails, traffic is switched to Link B immediately.

Figure 1-49 Configuring FRR for IPv4 static routes on the public network

 NOTE

In this example, interface1, interface2, and interface3 represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

Precautions

When configuring FRR for IPv4 static routes on the public network, ensure that there are at least two IPv4 static routes to the same destination address.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure two IPv4 static routes with Device A and Device B as the next hops on Device T.
2. Set a lower preference value for Link A on Device T so that Link A is preferentially selected.
3. Enable FRR for IPv4 static routes on Device T, and check the backup outbound interface and the backup next hop.
4. Configure static BFD for IPv4 static routes to speed up fault detection.

 NOTE

To speed up fault detection, configure dynamic or static BFD for IPv4 static routes. Static BFD for IPv4 static routes is used as an example because it is more common than dynamic BFD for IPv4 static routes on the live network.

5. Disable FRR for IPv4 static routes, and check the backup outbound interface and the backup next hop.

Data Preparation

To complete the configuration, you need preference values of IPv4 static routes.

Procedure

Step 1 Configure IP addresses for interfaces. For detailed configurations, see Configuration Files.

Step 2 Configure IPv4 static routes.

On Device A, configure IPv4 static routes.

```
[~DeviceA] ip route-static 172.16.1.0 24 GigabitEthernet1/0/0 192.168.10.1
[*DeviceA] ip route-static 172.17.1.0 24 GigabitEthernet2/0/0 192.168.11.1
[*DeviceA] commit
```

On Device B, configure static routes.

```
[~DeviceB] ip route-static 172.16.1.0 24 GigabitEthernet1/0/0 192.168.20.1
[*DeviceB] ip route-static 172.17.1.0 24 GigabitEthernet2/0/0 192.168.21.1
[*DeviceB] commit
```

On Device C, configure IPv4 static routes.

```
[~DeviceC] ip route-static 172.16.1.0 24 GigabitEthernet2/0/0 192.168.11.2
[*DeviceC] ip route-static 172.16.1.0 24 GigabitEthernet3/0/0 192.168.21.2
[*DeviceC] ip route-static 192.168.10.0 24 GigabitEthernet2/0/0 192.168.11.2
[*DeviceC] ip route-static 192.168.20.0 24 GigabitEthernet3/0/0 192.168.21.2
[*DeviceC] commit
```

On Device T, configure IPv4 static routes.

```
[~DeviceT] ip route-static 172.17.1.0 24 GigabitEthernet2/0/0 192.168.10.2
[*DeviceT] ip route-static 172.17.1.0 24 GigabitEthernet3/0/0 192.168.20.2
[*DeviceT] ip route-static 192.168.11.0 24 GigabitEthernet2/0/0 192.168.10.2
[*DeviceT] ip route-static 192.168.21.0 24 GigabitEthernet3/0/0 192.168.20.2
[*DeviceT] commit
[~DeviceT] quit
```

Check the IP routing table of Device T. The following command output shows that load balancing is performed between the two IPv4 static routes.

```
<DeviceT> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Destinations : 16      Routes : 16

          255.255.255.255/32 Direct 0   0        D  127.0.0.1   InLoopBack0
```

Step 3 Change the priorities of the IPv4 static routes.

Change the priorities of static routes on Device T.

```
<DeviceT> system-view
[~DeviceT] ip route-static 172.17.1.0 24 GigabitEthernet2/0/0 192.168.10.2 preference 40
[*DeviceT] commit
[~DeviceT] quit
```

Check the IP routing table of Device T. The following command output shows that the preference value of the IPv4 static route has been changed.

```
<DeviceT> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Destinations : 16      Routes : 16

BkPETunnelID: 0x0        BkPESecTunnelID: 0x0
BkIndirectID: 0x32000033
```

Step 5 Configure static BFD for IPv4 static routes.

- Configure a BFD session.

On Device T, configure a BFD session between Device T and Device C.

```
<DeviceT> system-view
[~DeviceT] bfd
[*DeviceT-bfd] quit
[*DeviceT] bfd aa bind peer-ip 192.168.11.1 source-ip 192.168.10.1
[*DeviceT-bfd-session-aa] discriminator local 10
[*DeviceT-bfd-session-aa] discriminator remote 20
[*DeviceT-bfd-session-aa] commit
[~DeviceT-bfd-session-aa] quit
```

On Device C, configure a BFD session between Device C and Device T.

```
<DeviceC> system-view
[~DeviceC] bfd
[*DeviceC-bfd] quit
[*DeviceC] bfd ab bind peer-ip 192.168.10.1 source-ip 192.168.11.1
[*DeviceC-bfd-session-ab] discriminator local 20
[*DeviceC-bfd-session-ab] discriminator remote 10
[*DeviceC-bfd-session-ab] commit
[~DeviceC-bfd-session-ab] quit
```

- Configure a static route and bind it to the BFD session.

On Device T, configure a static route and bind it to the BFD session named **aa**.

```
[~DeviceT] ip route-static 172.17.1.0 24 GigabitEthernet2/0/0 192.168.10.2 preference 40 track
bfd-session aa
```

Step 6 Simulate a fault on Link A.

```
<DeviceT> system-view
[~DeviceT] interface gigabitethernet 2/0/0
[~DeviceT-GigabitEthernet2/0/0] shutdown
[~DeviceT-GigabitEthernet2/0/0] commit
[~DeviceT-GigabitEthernet2/0/0] quit
[~DeviceT] quit
```

Check the routes to 172.17.1.0/24 on Device T.

```
<DeviceT> display ip routing-table 172.17.1.0 verbose
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
Routing Table : _public_
Summary Count : 1

Destination: 172.17.1.0/24

Example for Configuring Association between LDP and Static Routes

On an MPLS network with primary and secondary LSPs established by LSRs using static routes, association between LDP and static routes prevents traffic from being interrupted during traffic switchover or switchback.

Networking Requirements

On an MPLS network with primary and secondary LSPs established by LSRs using static routes, if association between LDP and static routes is not enabled, traffic is interrupted for a short period of time during traffic switchover from the primary LSP to the secondary LSP when the LDP session on the primary link fails (not because of a link fault) or during traffic switchback when the primary link recovers from a fault.

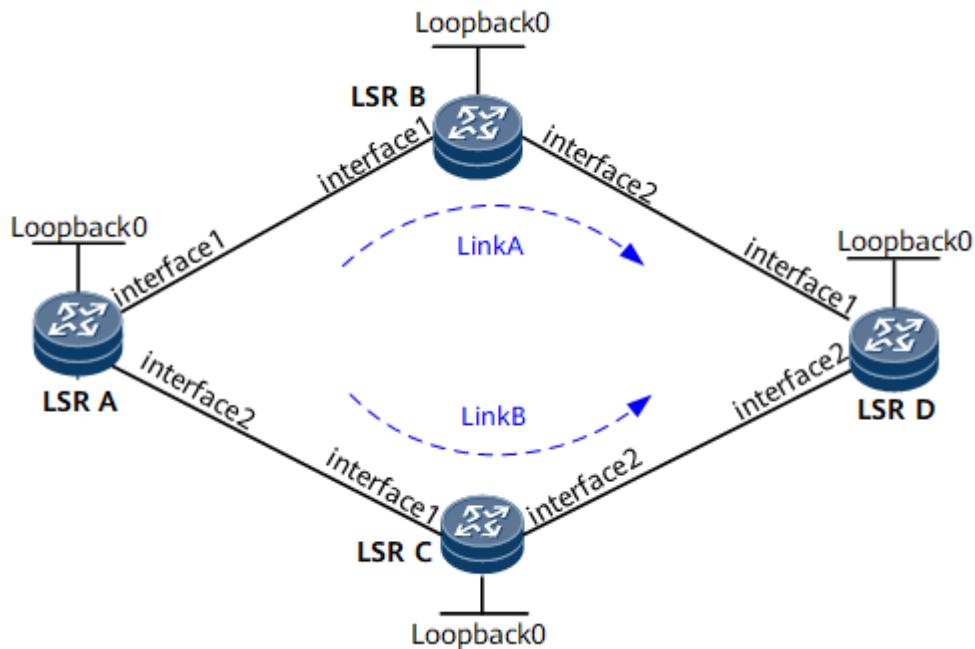

In [Figure 1-50](#), LSRA has two static routes to LSRD. One of the static routes passes through LSRB, whereas the other static route passes through LSRC. LDP LSPs are established based on the static routes. Link A is the primary link, whereas Link B is the backup link. It is required that association between LDP and static routes be configured to prevent MPLS traffic from being interrupted if the LDP session on Link A or Link B recovers from a fault.

Figure 1-50 Networking for configuring association between LDP and static routes

NOTE

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

Device Name	Interface Name	Interface IP Address	Device Name	Interface Name	Interface IP Address
LSRA	GE 1/0/0	10.1.1.1/30	LSRC	GE 1/0/0	10.2.1.2/30
	GE 2/0/0	10.2.1.1/30		GE 2/0/0	10.4.1.1/30
	Loopback0	1.1.1.1/32		Loopback0	3.3.3.3/32
LSRB	GE 1/0/0	10.1.1.2/30	LSRD	GE 1/0/0	10.3.1.2/30
	GE 2/0/0	10.3.1.1/30		GE 2/0/0	10.4.1.2/30
	Loopback0	2.2.2.2/32		Loopback0	4.4.4.4/32

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure static routes for each LSP to reach other LSRs.
2. Enable MPLS and MPLS LDP globally and on interfaces of LSRs.
3. Configure association between LDP and static routes and check configurations.

Data Preparation

To complete the configuration, you need the following data:

- IP addresses of interfaces on LSRs

- MPLS LSR IDs of LSRs
- Hold-down timer value

Procedure

Step 1 Assign an IP address and mask to each interface.

Configure an IP address for each interface based on [Figure 1-50](#). For configuration details, see "Configuration Files" in this section.

Step 2 Configure static routes on each node to ensure network connectivity.

Configure two static routes with different priorities from LSRA to LSRD, and two static routes with different priorities from LSRD to LSRA.

Configure LSRA.

```
[~LSRA] ip route-static 2.2.2.2 32 GigabitEthernet1/0/0 10.1.1.2
[*LSRA] ip route-static 3.3.3.3 32 GigabitEthernet2/0/0 10.2.1.2
[*LSRA] ip route-static 10.3.1.1 30 GigabitEthernet1/0/0
[*LSRA] ip route-static 10.4.1.1 30 GigabitEthernet2/0/0
[*LSRA] ip route-static 4.4.4.4 32 GigabitEthernet1/0/0 10.1.1.2 preference 40
[*LSRA] ip route-static 4.4.4.4 32 GigabitEthernet2/0/0 10.2.1.2 preference 60
[*LSRA] commit
```

Configure LSRB.

```
[~LSRB] ip route-static 1.1.1.1 32 GigabitEthernet1/0/0 10.1.1.1
[*LSRB] ip route-static 4.4.4.4 32 GigabitEthernet2/0/0 10.3.1.2
[*LSRB] commit
```

Configure LSRC.

```
[~LSRC] ip route-static 1.1.1.1 32 GigabitEthernet1/0/0 10.2.1.1
[*LSRC] ip route-static 4.4.4.4 32 GigabitEthernet2/0/0 10.4.1.2
[*LSRC] commit
```

Configure LSRD.

```
[~LSRD] ip route-static 2.2.2.2 32 GigabitEthernet1/0/0 10.3.1.1
[*LSRD] ip route-static 3.3.3.3 32 GigabitEthernet2/0/0 10.4.1.1
[*LSRD] ip route-static 10.1.1.2 30 GigabitEthernet1/0/0
[*LSRD] ip route-static 10.2.1.2 30 GigabitEthernet2/0/0
[*LSRD] ip route-static 1.1.1.1 32 GigabitEthernet1/0/0 10.3.1.1 preference 40
[*LSRD] ip route-static 1.1.1.1 32 GigabitEthernet2/0/0 10.4.1.1 preference 60
[*LSRD] commit
```

After completing the configurations, run the **display ip routing-table protocol static** command on each node to check the static route configurations. The following example uses the command output on LSRA.

```
[~LSRA] display ip routing-table protocol static
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
-----
public_Routing Table : Static
    Destinations : 5      Routes : 5      Configured Routes : 5

Static routing table status :
    Destinations : 5      Routes : 5

Destination/Mask Proto Pre Cost Flags NextHop      Interface
    2.2.2.2/32 Static 60 0      D 10.1.1.1      GigabitEthernet1/0/0
    3.3.3.3/32 Static 60 0      D 10.2.1.1      GigabitEthernet2/0/0
    4.4.4.4/32 Static 40 0      D 10.1.1.1      GigabitEthernet1/0/0
    10.3.1.0/30 Static 60 0      D 10.1.1.1      GigabitEthernet1/0/0
```

```
10.4.1.0/30 Static 60 0      D 10.2.1.1      GigabitEthernet2/0/0

Static routing table status : <Inactive>
Destinations : 0      Routes : 0
```

Step 3 Enable MPLS LDP on each LSR to set up LDP LSPs.

Configure LSRA.

```
[~LSRA] mpls lsr-id 1.1.1.1
[*LSRA] mpls
[*LSRA-mpls] quit
[*LSRA] mpls ldp
[*LSRA-mpls-ldp] commit
[*LSRA-mpls-ldp] quit
[~LSRA] interface GigabitEthernet1/0/0
[~LSRA-GigabitEthernet1/0/0] mpls
[*LSRA-GigabitEthernet1/0/0] mpls ldp
[*LSRA-GigabitEthernet1/0/0] commit
[*LSRA-GigabitEthernet1/0/0] quit
[~LSRA] interface GigabitEthernet2/0/0
[~LSRA-GigabitEthernet2/0/0] mpls
[*LSRA-GigabitEthernet2/0/0] mpls ldp
[*LSRA-GigabitEthernet2/0/0] commit
[*LSRA-GigabitEthernet2/0/0] quit
```

Repeat this step for LSRB, LSRC, and LSRD. For configuration details, see "Configuration Files" in this section.

Run the **display mpls ldp session** command on each node to view information about established LDP sessions (in **Operational** state). The following example uses the command output on LSRA.

```
[~LSRA] display mpls ldp session
LDP Session(s) in Public Network
Codes: LAM(Label Advertisement Mode), SsnAge Unit(DDDD:HH:MM)
An asterisk (*) before a session means the session is being deleted.

PeerID      Status    LAM  SsnRole  SsnAge      KASent/Rcv
-----
2.2.2.2:0   Operational DU  Passive  0000:15:34  3738/3738
3.3.3.3:0   Operational DU  Passive  0000:00:45  182/182
-----
TOTAL: 2 Session(s) Found.
```

Step 4 Configure association between LDP and static routes on LSRA and LSRD.

Configure LSRA.

```
[~LSRA] ip route-static 4.4.4.4 32 GigabitEthernet1/0/0 10.1.1.2 preference 40 ldp-sync
[*LSRA] interface GigabitEthernet1/0/0
[*LSRA-GigabitEthernet1/0/0] static-route timer ldp-sync hold-down 20
[*LSRA-GigabitEthernet1/0/0] commit
[~LSRA-GigabitEthernet1/0/0] quit
```

Configure LSRD.

```
[~LSRD] ip route-static 1.1.1.1 32 GigabitEthernet1/0/0 10.3.1.1 preference 40 ldp-sync
[*LSRD] interface GigabitEthernet1/0/0
[*LSRD-GigabitEthernet1/0/0] static-route timer ldp-sync hold-down 20
[*LSRD-GigabitEthernet1/0/0] commit
[~LSRD-GigabitEthernet1/0/0] quit
```

Step 5 Verify the configuration.

Display outbound interface status of the static route that is associated with LDP on LSRA.

```
[~LSRA] display static-route ldp-sync
```

```
Total number of routes enable Ldp-Sync: 1
-----
Interface GigabitEthernet1/0/0
Enable ldp-sync static routes number: 1
Static-route ldp-sync holddown timer: 20s
Sync state: Normal
Dest = 4.4.4.4, Mask = 32, NextHop = 10.1.1.2.
```

The command output shows that association between LDP and static routes has been configured (in **Normal** state).

- If the LDP session on Link A fails, traffic is switched to Link B immediately to ensure association between LDP and static routes and prevent a traffic interruption.
- If Link A fails and then recovers, the static route with the next hop of 10.1.1.2 is not preferentially selected until the hold-down timer (20 seconds) expires (by then the LDP session on Link A has been set up). Then traffic is switched back to Link A. In this way, association between LDP and static routes is ensured, and MPLS traffic is not interrupted.

----End

1.1.3 IPv6 Static Route Configuration

1.1.3.1 IPv6 Static Route Configuration

Static routes are applicable to networks with simple structures. Properly configuring and using static routes can improve network performance and guarantee the required bandwidth for important applications.

1.1.3.1.1 Overview of IPv6 Static Routes

Configuring IPv6 static routes can implement the interworking of simple networks.

Definition

Static routes are special routes that are configured by network administrators.

Purpose

On a simple network, only static routes can ensure that the network runs properly. If a router cannot run dynamic routing protocols or cannot generate routes to a destination network, you can configure static routes on the router.

Route selection can be controlled using static routes. Properly configuring and using static routes can improve network performance and guarantee the required bandwidth for important applications. When a network fault occurs or the network topology changes, however, static routes must be changed manually by the administrator.

1.1.3.1.2 Configuration Precautions for IPv6 Static Route

Feature Requirements

None

1.1.3.1.3 Configuring IPv6 Static Routes

On a network, you can control route selection by configuring IPv6 static routes.

Usage Scenario

On a small IPv6 network, you can achieve network connectivity by configuring IPv6 static routes. Compared with the use of dynamic routing protocols, configuring static routes saves bandwidth resources.

Pre-configuration Tasks

Before configuring an IPv6 static route, configure link layer protocol parameters and IPv6 addresses for interfaces and ensure that the status of the link layer protocol of the interface is Up.

Creating IPv6 Static Routes

To create an IPv6 static route, configure its destination IP address, outbound interface, and next hop.

Context

When creating a static route, you can specify an outbound interface, a next hop address, or both of them, depending on actual requirements.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Configure an IPv6 static route.

- Run one of the following commands to configure an IPv6 static route for the public network:
 - **ipv6 route-static** *dest-ipv6-address prefix-length interface-type interface-number* [*nexthop-ipv6-address*] [**preference** *preference* | **tag** *tag*] [**description** *text*]
 - **ipv6 route-static** *dest-ipv6-address prefix-length nexthop-ipv6-address* [**preference** *preference* | **tag** *tag*] * [**description** *text*]
 - **ipv6 route-static** *dest-ipv6-address prefix-length vpn-instance vpn-instance-name nexthop-ipv6-address* [**preference** *preference* | **tag** *tag*] * [**description** *text*]
 - **ipv6 route-static** *dest-ipv6-address prefix-length vpn-instance vpn-instance-name* [**preference** *preference* | **tag** *tag*] * [**description** *text*]
- Run one of the following commands to configure an IPv6 static route for a VPN instance:
 - **ipv6 route-static vpn-instance** *vpn-source-name dest-ipv6-address prefix-length* { *interface-name* | *interface-type interface-number* } [*nexthop-ipv6-address*] [**preference** *preference* | **tag** *tag*] * [**description** *text*]
 - **ipv6 route-static vpn-instance** *vpn-source-name dest-ipv6-address prefix-length nexthop-ipv6-address* [**preference** *preference* | **tag** *tag*] * [**description** *text*]

- **ipv6 route-static vpn-instance vpn-source-name dest-ipv6-address prefix-length { vpn-instance vpn-instance-name nexthop-ipv6-address | nexthop-ipv6-address [public] } [preference preference | tag tag] * [description text]**
- **ipv6 route-static vpn-instance vpn-source-name dest-ipv6-address prefix-length { vpn-instance vpn-instance-name | public } [preference preference | tag tag] * [description text]**
- To configure an IPv6 static route in the topology instance, run the **ipv6 route-static topology topology-name dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | nexthop-ipv6-address } [preference preference | tag tag] * [no-advertise | no-install] [description text]** command.

Step 3 Run commit

The configuration is committed.

----End

(Optional) Setting the Default Priority for IPv6 Static Routes

You can change default priority for IPv6 static routes.

Context

After an IPv6 static route is configured, the default priority is used if no priority is specified for the static route. After the default priority is re-set, the new default priority takes effect only on new IPv6 static routes.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run **ipv6 route-static default-preference preference**

The default preference value is configured for IPv6 static routes.

By default, the priority of IPv6 static routes is lower than those of OSPF and IS-IS routes. To allow IPv6 static routes to take effect when OSPF or IS-IS routes exist, configure the default priority of IPv6 static routes to be higher than that of OSPF or IS-IS routes before you configure IPv6 static routes. A smaller preference value indicates a higher priority.

Step 3 Run commit

The configuration is committed.

----End

(Optional) Enabling a Device to Recurse IPv6 Static Routes to ND Vlink Direct Routes

To prevent blackhole routes from being generated in a scenario where a Layer 2 network accesses a Layer 3 network, you can enable a device to recurse IPv6 static routes to ND Vlink direct routes.

Context

In a scenario where a Layer 2 network accesses a Layer 3 network, you can enable a device to recurse IPv6 static routes to ND Vlink direct routes. This prevents blackhole routes from being generated.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ipv6 route recursive-lookup nd vlink-direct-route protocol static**

The device is configured to recurse IPv6 static routes to ND Vlink direct routes.

The **ipv6 route recursive-lookup nd vlink-direct-route protocol static** command is mainly used in scenarios where Layer 2 accesses Layer 3. To allow IPv6 static routes to recurse only to ND Vlink direct routes, run the **ipv6 route-static** command with the **recursive-lookup host-route** parameter specified in addition to running the **ipv6 route recursive-lookup nd vlink-direct-route protocol static** command.

Step 3 Run **commit**

The configuration is committed.

----End

(Optional) Enabling a Device to Recurse IPv6 Static Routes to SRv6 Routes

By default, a device does not recurse static routes to SRv6 routes. In EVPN L3VPN HoVPN over SRv6 BE or EVPN L3VPN HoVPN over SRv6 TE Policy scenarios, you can enable a device to recurse static routes to SRv6 routes to prevent traffic black holes.

Context

In an EVPN L3VPN HoVPN over SRv6 BE or EVPN L3VPN HoVPN over SRv6 TE Policy scenario, if the next hop of a default route on an SPE is the SPE itself and the link between the SPE and the corresponding NPE fails, the UPE cannot detect the link fault. As a result, a traffic black hole occurs after traffic reaches the SPE. To resolve this problem, you need to specify the NPE's address (public or private) as the next-hop address of the default static route on the SPE. In this manner, the validity of the static route depends on whether the link between the SPE and NPE is available. In addition, you need to enable the SPE to recurse static routes to SRv6 routes. This configuration allows the SPE to withdraw this inactive route when the SPE-NPE link fails so that the UPE can detect the route withdrawal and no longer sends traffic to the SPE, thereby preventing a traffic black hole.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run `ipv6 route-static recursive-lookup inherit-label-route segment-routing-ipv6`

The device is enabled to recurse IPv6 static routes to SRv6 routes.

Step 3 Run `commit`

The configuration is committed.

----End

(Optional) Preventing an IPv6 Static Route from Being Selected If the BFD Session Associated with It Is in the AdminDown State

This section describes how to configure the router not to select an IPv6 static route if the BFD session associated with it is in the AdminDown state. This ensures that Huawei devices can interwork with non-Huawei devices.

Context

By default, an IPv6 static route can still be selected by Huawei devices even though the BFD session associated with it is in the AdminDown state, but not by non-Huawei devices. As a result, Huawei devices cannot interwork with non-Huawei devices.

To address this problem, run the **`ipv6 route-static track bfd-session admindown invalid`** command to configure the router not to select the IPv6 static route if the BFD session associated with it is in the AdminDown state.

Procedure

Step 1 Run `system-view`

The system view is displayed.

Step 2 Run `ipv6 route-static track bfd-session session-name bfd-name admindown invalid`

The router has been configured not to select the IPv6 static route if the BFD session associated with it is in the AdminDown state.

Step 3 Run `commit`

The configuration is committed.

----End

Verifying the IPv6 Static Route Configuration

After configuring an IPv6 static route, verify the configuration.

Prerequisites

An IPv6 static route has been configured.

Procedure

- Run the **display ipv6 routing-table** command to check brief information about the IPv6 routing table.
- Run the **display ipv6 routing-table verbose** command to check detailed information about the IPv6 routing table.
- Run the **display ipv6 routing-table protocol** command to check information about routes of a specified routing protocol.

----End

1.1.3.1.4 Configuring IPv6 Floating Static Routes

Configuring floating static routes helps to implement route backup and improve network reliability.

Usage Scenario

If there is a route to a specific destination, you can configure a static route with a low preference to implement route backup, which improves network reliability. This static route with a lower preference is called a floating static route. It is activated to forward packets only when the optimal route fails. When the optimal route recovers, this static route becomes inactive.

Floating static routes are used as follows:

- Two static routes with the same destination address but different priorities are configured, and the one with the lower priority functions as a backup.
- When a route of a dynamic routing protocol to a destination address exists, you can configure a static route to the destination address for data service forwarding temporarily if the dynamic routing protocol restarts.

Pre-configuration Tasks

Before configuring IPv6 floating static routes, configure link layer protocol parameters and IP addresses for interfaces and ensure that the status of the link layer protocol on the interfaces is Up.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run either of the following commands as required:

- Run **ipv6 route-static dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-destination-name [nexthop-ipv6-address] | nexthop-ipv6-address } [preference preference | tag tag]* [description text]**
An IPv6 floating static route is configured in public network.
- Run **ipv6 route-static vpn-instance vpn-source-name dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-destination-name [nexthop-ipv6-address] | nexthop-ipv6-address [public] } [preference preference | tag tag]* [description text]**

An IPv6 floating static route is configured in VPN network.

- Run **ipv6 route-static topology topology-name dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | nexthop-ipv6-address } [preference preference | tag tag] * [description text]**

An IPv6 floating static route is configured in a non-base topology instance.

The **preference** parameter specifies a route priority. The greater the value, the lower the priority. Therefore, make sure that the priority value of the floating static route is greater than that of the optimal route.

Step 3 Run commit

The configuration is committed.

----End

Checking the Configurations

After the configuration is complete, check the configuration results.

- Run the **display ipv6 routing-table ipv6-address [prefix-length]** command to check configurations about the optimal IPv6 static route to the specified destination network segment.
- Run the **display current-configuration | include static** command to check the configurations about the current static route.

1.1.3.1.5 Configuring IPv6 Static Route Detection

With IPv6 static route detection, if a link through which an IPv6 static route travels fails, a rapid link switchover is performed, preventing lengthy service interruptions.

Usage Scenario

Unlike dynamic routes, static routes do not have a detection mechanism. As a result, administrator intervention is required if a fault occurs on the network. To prevent the need for administrator intervention, deploy IPv6 static route detection to implement automatic rapid link switchover if a link failure occurs. IPv6 static route detection prevents lengthy service interruptions.

The following IPv6 static route detection methods are available:

- BFD for IPv6 static routes: After BFD for IPv6 static routes is configured, each static route can be bound to a BFD session. BFD for IPv6 static routes implements millisecond-level detection. BFD is classified as static BFD or dynamic BFD.
- Network quality analysis (NQA) for IPv6 static routes: Although BFD for IPv6 static routes implements fast link fault detection, it cannot be deployed in some scenarios (when Layer 2 devices exist on the network, for example) because both ends of the link must support BFD. NQA for IPv6 static routes, however, can monitor the link status of a static route even when only one end supports NQA. NQA for IPv6 static routes implements second-level detection.

NOTE

Only one of the IPv6 static route detection methods can be deployed. Therefore, choose one based on the live network requirements.

Pre-configuration Tasks

Before configuring IPv6 static route detection, configure link-layer protocol parameters and IPv6 addresses for interfaces to ensure that the link layer protocol of each interface is Up.

Configuring Dynamic BFD for IPv6 Static Routes

Dynamic BFD for IPv6 static routes enables devices to fast detect link changes, improving network reliability.

Usage Scenario

To use BFD sessions to provide link detection for IPv6 static routes on the public network, you can bind static routes to BFD sessions. One IPv6 static route can be bound to one BFD session.

Optimal IPv6 static routes are delivered to the forwarding table for packet forwarding. However, IPv6 static routes cannot detect the status of the link to the next hop. You can bind IPv6 static routes to BFD sessions. A BFD session can fast detect changes over a link and inform the routing management system of the changes. The routing management system immediately deletes the IPv6 static route that is bound to the BFD session from the forwarding table and recalculates another active route. In this manner, fast route convergence is implemented.

Pre-configuration Tasks

Before configuring dynamic BFD for IPv6 static routes, configure parameters of the link layer protocol and IPv6 addresses for interfaces and ensure that the link layer protocol on the interfaces is up.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **bfd**

BFD is enabled globally on the local device.

NOTE

Running the **undo bfd** command will delete the parameters of the BFD session bound to the static route. As a result, the static route status may change, and services may be interrupted.

Step 3 Run **quit**

Return to the system view.

Step 4 (Optional) Run **ipv6 route-static default-bfd { detect-multiplier multiplier | min-rx-interval min-rx-interval | min-tx-interval min-tx-interval }***

Global BFD parameters are configured for IPv6 static routes.

Step 5 Run **ipv6 route-static bfd [interface-type interface-number | vpn-instance vpn-destination-name] nexthop-address [local-address ipv6-address] [detect-**

multiplier multiplier] [min-rx-interval min-rx-interval] [min-tx-interval min-tx-interval]*

BFD parameters are set for a single IPv6 static route.

 NOTE

If the *interface-type interface-number* parameter is not set, the **local-address ipv6-address** parameter must be specified.

If none of **min-rx-interval**, **min-tx-interval**, or **detect-multiplier** is specified, the default values of the global BFD parameters are used.

Step 6 Run either of the following commands as required:

- Run **ipv6 route-static dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-destination-name [nexthop-ipv6-address] | nexthop-ipv6-address } [preference preference | tag tag]* bfd enable [description text]**
A BFD session is bound to an IPv6 static route on the public network.
- Run **ipv6 route-static vpn-instance vpn-source-name dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-destination-name [nexthop-ipv6-address] | nexthop-ipv6-address [public] } [preference preference | tag tag]* bfd enable [description text]**
A BFD session is bound to an IPv6 static route on the VPN network.

 NOTE

The outbound interface and next hop IP address specified when binding the IPv6 static route to a BFD session must be the same as those specified when configuring BFD parameters for the IPv6 static route.

Step 7 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

Run the following commands to check the previous configuration.

- Run the **display bfd session { all | discriminator descr-value } [verbose]** command to check information about BFD sessions.
- Run the **display current-configuration | include bfd** command to check configurations of BFD for IPv6 static routes.

Information about a BFD session can be viewed only after parameters of the BFD session are set and the BFD session is established.

If a BFD session has been established, the status of the BFD session is Up. Run the **display current-configuration | include bfd** command in the system view, and you can see that the BFD session has been bound to a static route.

Configuring Static BFD for IPv6 Static Routes

Static BFD for IPv6 static routes enables devices to fast detect link changes, improving network reliability.

Usage Scenario

To use BFD sessions to provide link detection for IPv6 static routes on the public network, you can bind IPv6 static routes to BFD sessions. One IPv6 static route can be bound to one BFD session.

Optimal IPv6 static routes are delivered to the forwarding table for packet forwarding. However, IPv6 static routes cannot detect the status of the link to the next hop. You can bind IPv6 static routes to BFD sessions. A BFD session can fast detect changes over a link and inform the routing management system of the changes. The routing management system immediately deletes the static route that is bound to the BFD session from the forwarding table and recalculates another active route. In this manner, fast route convergence is implemented.

Pre-configuration Tasks

Before configuring static BFD for IPv6 static routes, complete the following tasks:

- Configure link layer protocol parameters and IP addresses for interfaces and ensure that the link layer protocol on the interfaces is up.

Procedure

Step 1 Configure a BFD Session.

- Run **system-view**
The system view is displayed.
- Run **bfd**
BFD is globally enabled.
- Run **quit**
The system view is displayed.
- Run **bfd session-name bind peer-ipv6 peer-ipv6**
The binding between a BFD session for IPv6 and a peer IPv6 address is created, and the BFD session view is displayed.
- Run **discriminator local discr-value**
The local discriminator of a static BFD session is set.
- Run **discriminator remote discr-value**
The remote discriminator of a static BFD session is set.

NOTE

For details of optional procedures for configuring a BFD session, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide - Network Reliability*.

- Run **commit**
The configuration is committed.

Step 2 Associate an IPv6 static route with a BFD session.

- Run **system-view**
The system view is displayed.

2. Run either of the following commands as required:
 - Run **ipv6 route-static dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-instance-name nexthop-ipv6-address | nexthop-ipv6-address } [preference preference | tag tag] * track bfd-session cfg-name [description text]**
A BFD session is bound to an IPv6 static route on the public network.
 - Run **ipv6 route-static vpn-instance vpn-source-name dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-destination-name [nexthop-ipv6-address] | nexthop-ipv6-address [public] } [preference preference | tag tag] * track bfd-session cfg-name [description text]**
A static BFD session is bound to an IPv6 static route on the VPN network.
3. Run **commit**
The configuration is committed.
----End

Verifying the Configuration

After configuring static BFD for IPv6 static routes, verify the configuration.

- Run the **display bfd session { all | discriminator discr-value } [verbose]** command to check information about BFD sessions.
- Run the **display current-configuration | include bfd** command to check configurations of BFD for IPv6 static routes.

Information about a BFD session can be viewed only after parameters of the BFD session are set and the BFD session is established.

If a BFD session has been established, the status of the BFD session is up. Run the **display current-configuration | include bfd** command in the system view, and you can see that the BFD session has been bound to a static route.

Configuring NQA for IPv6 Static Routes

If an IPv6 static route is associated with a network quality analysis (NQA) test instance, NQA tests the link status periodically. If NQA detects a fault along the associated IPv6 static route, the IPv6 static route is deleted, and traffic is switched to another route.

Usage Scenario

On live networks, the link status of IPv6 static routes must be monitored in real time so that a link switchover can be performed immediately if a link fails. Bidirectional Forwarding Detection (BFD) for IPv6 static routes can implement detection within milliseconds. However, BFD for IPv6 static routes requires that both ends of a link support BFD.

NQA for IPv6 static routes can monitor the link status of static routes as long as one end supports NQA.

If a link fails, an NQA test instance immediately detects the fault and instructs the routing management module to delete the IPv6 static route associated with the

NQA test instance from the IPv6 routing table. Traffic is then forwarded over another link.

 NOTE

Currently, NQA test instances of only the ICMP or TCP type can be associated with static routes to implement fast fault detection.

Pre-configuration Tasks

Before configuring NQA for IPv6 static routes, configure parameters of the link layer protocol and IPv6 addresses for interfaces and ensure that the link layer protocol on the interfaces is up.

Procedure

Step 1 Configure an NQA test instance of the ICMP or TCP type.

1. Run **system-view**

The system view is displayed.

2. Run **nqa test-instance admin-name test-name**

An NQA test instance is created, and the test instance view is displayed.

 NOTE

Running the **undo nqa all-test-instance** command will delete the parameters of the NQA test instance bound to the static route. As a result, the static route status may change, and services may be interrupted.

3. Run **test-type { icmp | tcp }**

The type of the test instance is set to ICMP or TCP.

4. Run **destination-address ipv6 destAddress6**

A destination address is configured.

In an NQA test instance, you can specify an NQA server by running the **destination-address** command to configure a destination address for the NQA test instance.

5. Run any of the following commands to start an NQA test instance:

- **start at [yyyy/mm/dd] hh:mm:ss [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start delay { seconds second | hh:mm:ss } [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start now [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start daily hh:mm:ss to hh:mm:ss [begin { yyyy/mm/dd | yyyy-mm-dd }] [end { yyyy/mm/dd | yyyy-mm-dd }]**

 NOTE

For details of optional procedures when configuring an ICMP NQA test instance, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide - System Monitor*.

6. Run **commit**

The configuration is committed.

Step 2 Associate an IPv6 static route with an NQA test instance.

1. Run **system-view**

The system view is displayed.

2. Run either of the following commands as required to associate an IPv6 static route with an NQA test instance:

- To associate an IPv6 static route with an NQA test instance on the public network, run the **ipv6 route-static dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-destination-name nexthop-ipv6-address | vpn-instance vpn-destination-name | nexthop-ipv6-address } [preference preference | tag tag] * track nqa admin-name test-name [description text]** command.
- To associate an IPv6 static route with an NQA test instance in a VPN instance, run the **ipv6 route-static vpn-instance vpn-source-name dest-ipv6-address prefix-length { interface-type interface-number [nexthop-ipv6-address] | vpn-instance vpn-destination-name nexthop-ipv6-address | vpn-instance vpn-destination-name | public | nexthop-ipv6-address [public] } [preference preference | tag tag] * track nqa admin-name test-name [description text]** command.

3. Run **commit**

The configuration is committed.

NOTE

Precautions for associating a static route with an NQA test instance are as follows:

- The destination address of an NQA test instance cannot be the destination address of an associated static route.
- If the static route associated with one NQA test instance is associated with another NQA test instance, the association between the static route and the original NQA test instance is deleted.
- An NQA test instance must have been created before you associate it with a static route.

----End

Verifying the Configuration

After configuring NQA for IPv6 static routes, verify the configuration.

- Run the **display current-configuration | include nqa** command to check the configurations of NQA for IPv6 static routes.
- Run the **display nqa results [test-instance admin-name test-name]** command to check the NQA test results.

NOTE

The NQA test results cannot be displayed automatically. You need to run the **display nqa results** command to view the results.

Configuring NQA Group for IPv6 Static Route

After an IPv6 static route is associated with an NQA group, if the NQA group detects a link fault, it withdraws the IPv6 static route, triggering traffic switching and ensuring network stability.

Usage Scenario

On live networks, the status of IPv6 static routes needs to be monitored in real time to ensure network stability. If the link status changes, a primary/backup link switchover is performed. NQA for IPv6 static route can monitor only a single link. To enable a static route to use NQA test instances to monitor multiple links, you can bind these NQA test instances to the same NQA group and associate the static route with the NQA group.

If a link fault occurs, the NQA group can collect statistics on the status changes of all NQA test instances bound to the NQA group and determine whether to change its status according to the configured operation. When the status of the NQA group changes, the NQA group instructs the RM module to delete the IPv6 static route associated with the NQA group from the IP routing table. Traffic is then forwarded along another path, implementing a link switchover.

Pre-configuration Tasks

Before configuring NQA group for IPv6 static route, complete the following task:

- Configure link-layer protocol parameters and IP addresses for interfaces to ensure that the link layer protocol of each interface is up.

Procedure

- Configure multiple NQA test instances of the ICMP or TCP type.
 - Run **system-view**
The system view is displayed.
 - Run **nqa test-instance admin-name test-name**
An NQA test instance is created, and the test instance view is displayed.
 - Run **test-type { icmp | tcp }**
The test instance type is set to ICMP or TCP.
 - Run **destination-address ipv6 destAddress6**
A destination address is configured.
In an NQA test instance, you can specify the destination end by running the **destination-address** command to configure a destination address for the NQA test instance.
 - Run any of the following commands to start an NQA test instance:
 - start at [yyyy/mm/dd] hh:mm:ss [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
 - start delay { seconds second | hh:mm:ss } [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**

- **start now [end { at [yyyy/mm/dd] hh:mm:ss | delay { seconds second | hh:mm:ss } | lifetime { seconds second | hh:mm:ss } }]**
- **start daily hh:mm:ss to hh:mm:ss [begin { yyyy/mm/dd | yyyy-mm-dd }] [end { yyyy/mm/dd | yyyy-mm-dd }]**

 NOTE

For more optional configurations of NQA test instances, see the *HUAWEI NetEngine 8100 X/NetEngine 8000 X/NetEngine 8000E X series Router Configuration Guide - System Monitor*.

- f. Run **commit**
The configuration is committed.
 - g. Repeat the preceding steps to configure multiple NQA test instances of the ICMP or TCP type.
- Bind the preceding NQA test instances to an NQA group.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **nqa group group-name**
An NQA group is created, and the NQA group view is displayed.
 - c. Run **nqa test-instance admin-name test-name**
An NQA test instance is bound to the NQA group.
Run this command multiple times to bind multiple NQA test instances to the NQA group.

 NOTE

The NQA test instances bound to the same NQA group must be of the same type: ICMP or TCP.

- d. Run **operator { and | or }**
The operation type between test instances in the NQA group is set to AND or OR.
By default, the operation type between test instances is **or**.
 - e. (Optional) Run **description string**
A description is configured for the NQA group.
 - f. Run **commit**
The configuration is committed.
- Bind an IPv6 static route to the NQA group.
 - a. Run **system-view**
The system view is displayed.
 - b. Bind an IPv6 static route to the NQA group.
 - To configure an IPv6 static route on the public network and associate the route with the NQA group, run the **ipv6 route-static ip-address { mask | mask-length } { nexthop-address | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name**

*nexthop-address } [preference preference | tag tag] * track nqa-group group-name [description text] command.*

- To configure an IPv6 static route on a VPN and associate the route with the NQA group, run the **ipv6 route-static vpn-instance vpn-source-name destination-address { mask | mask-length } { nexthop-address [public] | interface-type interface-number [nexthop-address] | vpn-instance vpn-instance-name nexthop-address } [preference preference | tag tag] * track nqa-group group-name [description text] command.**

c. Run **commit**

The configuration is committed.

 **NOTE**

When configuring NQA group for IPv6 static route, pay attention to the following points:

- The destination address of an NQA group cannot be the destination address of an associated static route.
- If a static route is associated with another NQA group, the association between the static route and the current NQA group is removed.
- A static route cannot be associated with an NQA group that has not been created.

----End

Verifying the Configuration

After the configuration is complete, verify it.

- Run the **display static-route ipv6 routing-table** command to check information about IPv6 static routes.
- Run the **display current-configuration | include nqa-group** command to check the configurations of NQA group for IPv6 static route.
- Run the **display nqa group [group-name]** command to check the test result of the NQA group.

 **NOTE**

The test result of the NQA group cannot be displayed automatically. You need to run the **display nqa group** command to view the result.

1.1.3.1.6 Configuring FRR for IPv6 Static Routes

Fast ReRoute (FRR) is applicable to services that are sensitive to packet delay and packet loss. FRR can be configured for IPv6 static routes to protect traffic using backup links.

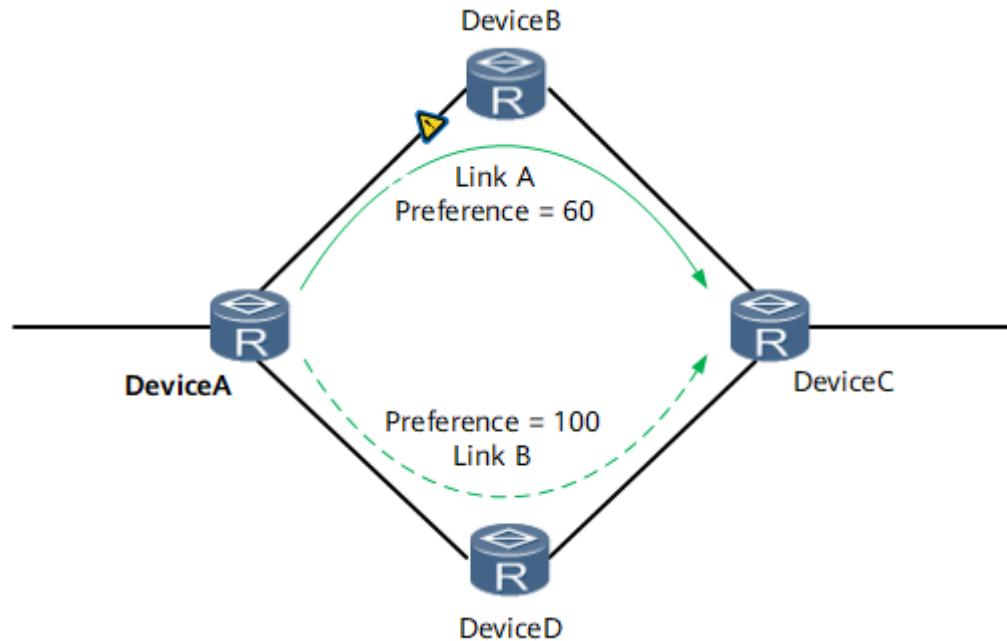

Usage Scenario

FRR is applicable to IP services that are sensitive to delay and packet loss. FRR minimizes the impact of link faults on services.

If two static routes with the same prefix but different priorities are configured, they can implement FRR. The route with the higher priority is the primary route,

and the route with the lower priority is the backup route. If the link that the primary route passes fails, traffic is rapidly switched to the backup route, thereby reducing the number of lost packets. On the network shown in [Figure 1-51](#), two static routes with different priorities from DeviceA to DeviceC work in primary/backup mode. The two routes are both delivered to the forwarding table. When the primary link A is normal, traffic is transmitted through link A. If link A fails, FRR allows traffic to be quickly switched to link B.

[Figure 1-51](#) FRR for IPv6 static routes

Pre-configuration Tasks

Before configuring FRR for IPv6 static routes, complete the following tasks:

- Configure parameters of the link layer protocol and IPv6 addresses for interfaces and ensure that the link layer protocol on the interfaces is up.
- [Configure dynamic BFD for IPv6 static routes](#) or [configure static BFD for IPv6 static routes](#) to speed up fault detection.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run **ipv6 route-static frr [vpn-instance vpn-instance-name]**

FRR is enabled for public or VPN IPv6 static routes.

NOTE

To implement route backup by configuring FRR for static routes, you need to specify different priorities for these static routes.

Step 3 Run commit

The configuration is committed.

----End

Verifying the Configuration

After configuring FRR for IPv6 static routes, verify the configuration.

- Run the **display ipv6 routing-table verbose** command to check detailed information about the backup outbound interface and the backup next hop in the routing table.
- Run the **display ipv6 routing-table *ipv6-address* [prefix-length] [longer-match] verbose** command to check detailed information about the backup outbound interface and the backup next hop in the routing table.

1.1.3.1.7 Configuration Examples for IPv6 Static Routes

This section provides configuration examples of IPv6 static routes.

Example for Configuring IPv6 Static Routes

You can configure IPv6 static routes to interconnect any two devices on an IPv6 network.

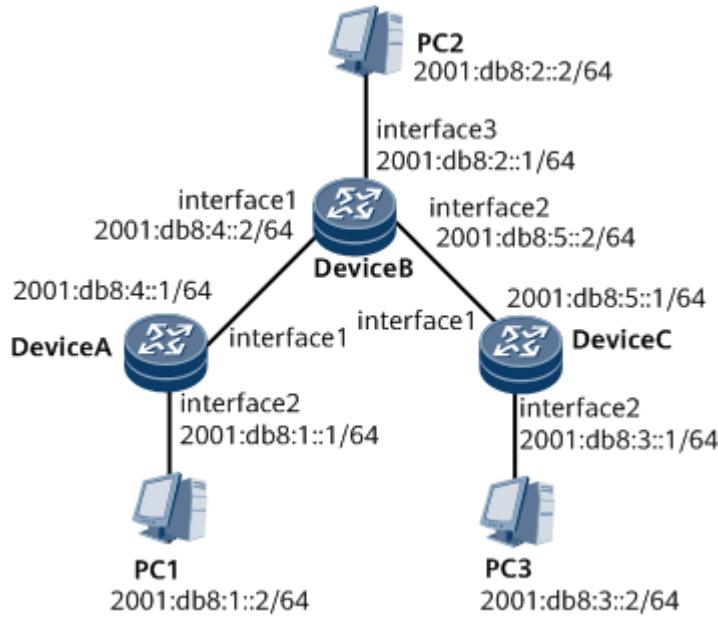

Networking Requirements

On the network shown in [Figure 1-52](#), the prefix of all the IPv6 addresses is 64. It is required that IPv6 static routes be configured between routers to ensure that all hosts communicate with routers. GE interfaces on routers use IPv6 link-local addresses.

Figure 1-52 Networking for configuring IPv6 static routes

Interfaces 1 through 3 in this example represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

Precautions

When configuring an IPv6 static route, specify a next hop address if the outbound interface is of the broadcast type.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure IPv6 addresses for GE interfaces on each router.
2. Configure the IPv6 static route and the default route on each router.
3. Configure the IPv6 default gateway on each host so that any two hosts can communicate with each other.

Data Preparation

To complete the configuration, you need the following data:

- Default route with GE 1/0/0 as the outbound interface on Device A
- Static route to 2001:db8:1:: 64 with GE 1/0/0 as the outbound interface on Device B
- Static route to 2001:db8:3:: 64 with GE 2/0/0 as the outbound interface on Device B
- Default route with GE 1/0/0 as the outbound interface on Device C
- Default gateways of PC1, PC2, and PC3

Procedure

Step 1 Configure an IPv6 address for each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure IPv6 static routes.

Configure an IPv6 default route on Device A.

```
[~DeviceA] ipv6 route-static :: 0 gigabitethernet 1/0/0 2001:db8:4::2
[*DeviceA] commit
```

Configure two IPv6 static routes on Device B.

```
[~DeviceB] ipv6 route-static 2001:db8:1:: 64 gigabitethernet 1/0/0 2001:db8:4::1
[*DeviceB] ipv6 route-static 2001:db8:3:: 64 gigabitethernet 2/0/0 2001:db8:5::1
[*DeviceB] commit
```

Configure an IPv6 default route on Device C.

```
[~DeviceC] ipv6 route-static :: 0 gigabitethernet 1/0/0 2001:db8:5::2
[*DeviceC] commit
```

Step 3 Configure host addresses and gateways.

Configure IPv6 addresses for hosts, and then configure the default gateways of PC1, PC2, and PC3 as 2001:db8:1::1, 2001:db8:2::1, and 2001:db8:3::1, respectively.

Step 4 Verify the configuration.

Check the IPv6 routing table of Device A.

```
[~DeviceA] display ipv6 routing-table
Routing Table : _public_
Destinations : 9      Routes : 9

Destination : ::          PrefixLength : 0

```

Example for Configuring IPv6 Floating Static Routes

IPv6 Floating static routes can be used for the static route backup.

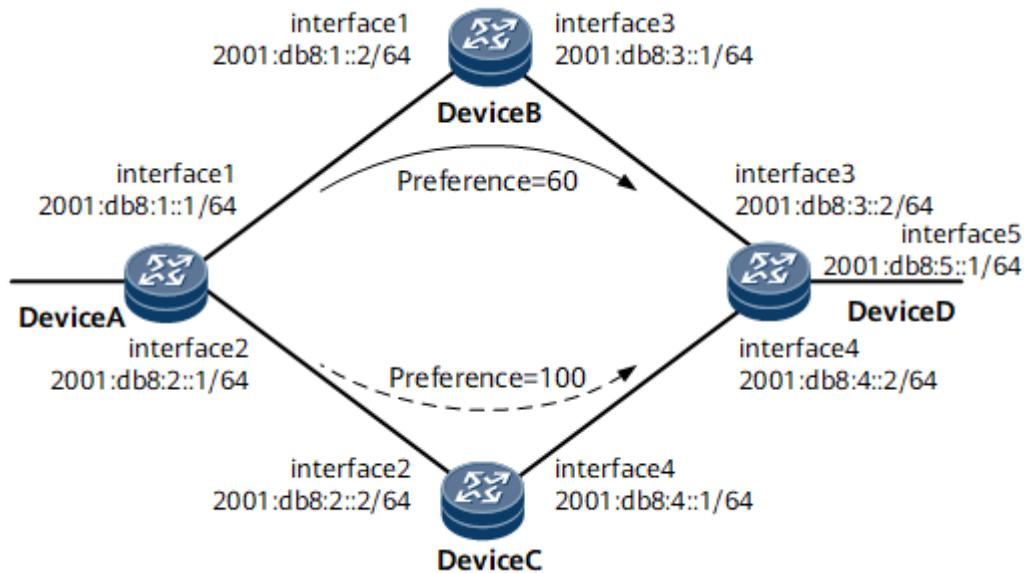

Networking Requirements

Figure 1-53 shows the IPv6 addresses and masks of each router interface and a host. Two IPv6 static routes to 2001:db8:5::/64 are configured on Device A. The primary static route passes through Device B, and the floating static route passes through Device C.

Figure 1-53 Networking for configuring IPv6 floating static routes

Interfaces 1 through 5 in this example represent GE 1/0/1, GE 1/0/2, GE 1/0/3, GE 2/0/3, and GE 3/0/3, respectively.

Precautions

When configuring an IPv6 floating static route, a next-hop address of this route must be specified if the outbound interface is of the broadcast type.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure an IPv6 address for each interface of each router.
2. On Devices B and C, configure IPv6 static routes to 2001:db8:5::/64.
3. On Device A, configure two IPv6 static routes to 2001:db8:5::/64 with different priorities.
4. On Device D, configure IPv6 static routes to 2001:db8:1::/64 and 2001:db8:2::/64 so that routers can communicate.

Data Preparation

To complete the configuration, you need the following data:

- On Device A, priority values of two static routes (60 for the one with 2001:db8:1::2 as the next hop address and 100 for the one with 2001:db8:2::2 as the next-hop address)

Procedure

Step 1 Configure an IPv6 address for each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure IPv6 static routes.

```
# Configure IPv6 static routes on Device B.
```

```
[~DeviceB] ipv6 route-static 2001:db8:5:: 64 2001:db8:3::2
[*DeviceB] commit
```

Configure IPv6 static routes on Device C.

```
[~DeviceC] ipv6 route-static 2001:db8:5:: 64 2001:db8:4::2
[*DeviceC] commit
```

Configure IPv6 static routes on Device A.

```
[*DeviceA] ipv6 route-static 2001:db8:5:: 64 2001:db8:1::2
[*DeviceA] ipv6 route-static 2001:db8:5:: 64 2001:db8:2::2 preference 100
[*DeviceA] commit
```

Configure IPv6 static routes on Device D.

```
[~DeviceD] ipv6 route-static 2001:db8:1:: 64 2001:db8:3::1
[*DeviceD] ipv6 route-static 2001:db8:2:: 64 2001:db8:4::1
[*DeviceD] commit
```

Step 3 Verify the configuration.

View information about static routes in the IP routing table of Device A.

```
[~DeviceA] display ipv6 routing-table protocol static
 _public_ Routing Table : Static
Summary Count : 1

Static routing table status : <Active>
Summary Count : 1

Destination : 2001:db8:5::          PrefixLength : 64
NextHop    : 2001:db8:1::2          Preference   : 60
Cost       : 0                      Protocol     : Static
RelayNextHop : 2001:db8:1::2        TunnelID    : 0x0
Interface   : GigabitEthernet1/0/1   Flags       : RD

Static routing table status : <Inactive>
Summary Count : 0
```

Use the **tracert ipv6** command to check the connectivity on Device A.

```
<DeviceA> tracert ipv6 2001:db8:5::1
traceroute to 2001:db8:5::1 30 hops max,60 bytes packet
1 2001:db8:1::2 195 ms 5 ms 2 ms
2 * 2001:db8:3::2 45 ms !N 5 ms !N
```

Run the **shutdown** command on GE 1/0/1 of Device A to simulate a link fault.

```
[~DeviceA] interface GigabitEthernet 1/0/1
[~DeviceA-GigabitEthernet1/0/1] shutdown
[*DeviceA-GigabitEthernet1/0/1] commit
[*DeviceA-GigabitEthernet1/0/1] quit
[~DeviceA] quit
```

View information about static routes in the IP routing table of Device A. The route to 2001:db8:5::/64 switches to the floating static route with next hop 2001:db8:2::2.

```
<DeviceA> display ipv6 routing-table protocol static
 _public_ Routing Table : Static
Summary Count : 1

Static routing table status : <Active>
Summary Count : 1

Destination : 2001:db8:5::          PrefixLength : 64
NextHop    : 2001:db8:2::2          Preference   : 100
Cost       : 0                      Protocol     : Static
RelayNextHop : 2001:db8:2::2        TunnelID    : 0x0
Interface   : GigabitEthernet1/0/2   Flags       : RD
```

```
Static routing table status : <Inactive>
Summary Count : 0
```

Use the **tracert ipv6** command to check the connectivity on Device A.

```
<DeviceA> tracert ipv6 2001:db8:5::1
traceroute to 2001:db8:5::1 30 hops max,60 bytes packet
1 2001:db8:2::2 87 ms 2 ms 4 ms
2 * 2001:db8:4::2 6 ms !N 2 ms !N
```

----End

#  
return
```

Example for Configuring Dynamic BFD for IPv6 Static Routes

Dynamic BFD for IPv6 static routes can fast detect link failures.

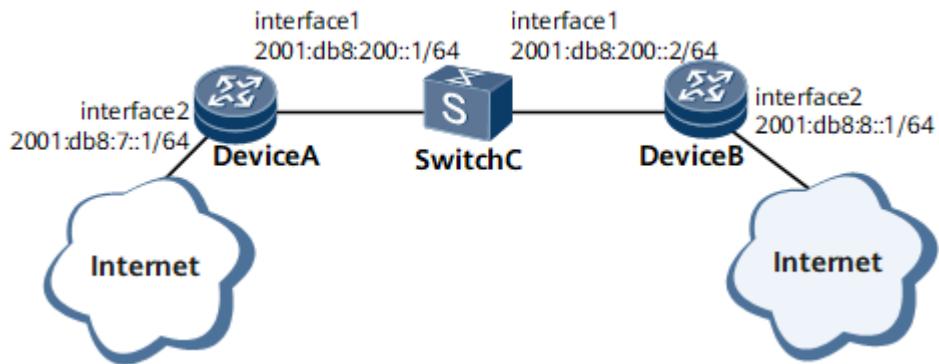

Networking Requirements

On the network shown in [Figure 1-54](#), Device A is connected to Device B through Switch C. A static default route is configured on Device A so that Device A can communicate with external devices. A BFD session is configured between Device A and Device B to detect whether a link fault occurs.

Figure 1-54 Networking for configuring dynamic BFD for IPv6 static routes

NOTE

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

Precautions

When configuring dynamic BFD for IPv6 static routes, note the following points:

- BFD has been enabled globally.
- The parameters configured on the two ends of a BFD session must be consistent.

Configuration Roadmap

The configuration roadmap is as follows:

1. On Device A, configure an IPv6 static route to Device B.
2. Configure dynamic BFD for IPv6 static routes.

Data Preparation

To complete the configuration, you need the following data:

- Peer IPv6 address to be detected by BFD
- Default values of the local detection multiplier and of the minimum intervals at which BFD Control packets are sent and received

Procedure

Step 1 Configure an IPv6 address for each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure IPv6 static routes.

On Device A, configure a static route to 2001:db8:8::1/64.

```
[~DeviceA] ipv6 route-static 2001:db8:8:: 64 2001:db8:200::2  
[*DeviceA] commit
```

On Device A, check the IPv6 routing table. The following command output shows that static routes exist in the IPv6 routing table.

```
[~DeviceA] display ipv6 routing-table  
Routing Table : _public_  
Destinations : 6 Routes : 6

RelayNextHop : :: TunnelID : 0x0
Interface  : NULL0 Flags    : D
```

On Device B, configure the static route to 2001:db8:7::1/64.

```
[~DeviceB] ipv6 route-static 2001:db8:7:: 64 2001:db8:200::1
[*DeviceB] commit
```

Step 3 Configure dynamic BFD for static routes.

On Device A, bind a static route to a BFD session.

```
[~DeviceA] bfd
[*DeviceA-bfd] quit
[*DeviceA] ipv6 route-static bfd 2001:db8:200::2 local-address 2001:db8:200::1
[*DeviceA] ipv6 route-static 2001:db8:8:: 64 2001:db8:200::2 bfd enable
[*DeviceA] commit
```

On Device B, bind a static route to a BFD session.

```
[~DeviceB] bfd
[*DeviceB-bfd] quit
[*DeviceB] ipv6 route-static bfd 2001:db8:200::1 local-address 2001:db8:200::2
[*DeviceB] ipv6 route-static 2001:db8:7:: 64 2001:db8:200::1 bfd enable
[*DeviceB] commit
```

Step 4 Verify the configuration.

After the configuration is complete, you can view that a BFD session has been established between Device A and Device B and is Up and that a static route is bound to it.

Use the command output on Device A as an example.

```
[~DeviceA] display bfd session all verbose
(w): State in WTR

Example for Configuring Static BFD for IPv6 Static Routes

To improve IPv6 network reliability, you can configure static BFD for IPv6 static routes to fast detect link failures and speed up route convergence.

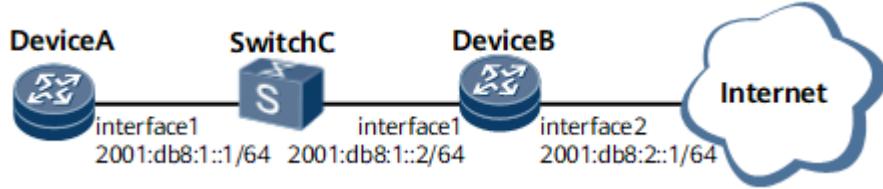

Networking Requirements

On the network shown in [Figure 1-55](#), Device A is connected to Device B through Switch C. A static default route is configured on Device A so that Device A can communicate with external devices. In addition, a BFD session is configured between Device A and Device B to rapidly detect link faults if any.

Figure 1-55 Configuring static BFD for IPv6 static routes

 NOTE

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure a BFD session on Device A and Device B to detect the link between the two devices.
2. Configure a default static route from Device A to the external network and bind the default static route to a BFD session.

Data Preparation

To complete the configuration, you need the following data:

- Peer IPv6 address to be detected by BFD
- Local discriminator and remote discriminator of a BFD session
- Default values of the local detection multiplier and of the minimum intervals at which BFD Control packets are sent and received

Procedure

Step 1 Configure an IPv6 address for each interface.

For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure a BFD session between Device A and Device B.

On Device A, configure a BFD session between Device A and Device B.

```
<DeviceA> system-view
[~DeviceA] bfd
[*DeviceA-bfd] quit
[*DeviceA] bfd aa bind peer-ipv6 2001:db8:1::2
[*DeviceA-bfd-session-aa] discriminator local 10
[*DeviceA-bfd-session-aa] discriminator remote 20
[*DeviceA-bfd-session-aa] commit
[~DeviceA-bfd-session-aa] quit
```

On Device B, configure a BFD session between Device A and Device B.

```
<DeviceB> system-view
[~DeviceB] bfd
[*DeviceB-bfd] quit
[*DeviceB] bfd bb bind peer-ipv6 2001:db8:1::1
[*DeviceB-bfd-session-bb] discriminator local 20
[*DeviceB-bfd-session-bb] discriminator remote 10
```

```
[*DeviceB-bfd-session-bb] commit  
[~DeviceB-bfd-session-bb] quit
```

Step 3 Configure a default static route and bind it to a BFD session.

On Device A, configure a default static route to the external network and bind it to BFD session named aa.

```
[~DeviceA] ipv6 route-static 0::0 0 2001:db8:1::2 track bfd-session aa
```

Step 4 Verify the configuration.

Run the **display bfd session all** command on Device A and Device B. The command output shows that a BFD session has been established and is Up. Then, run the **display current-configuration | include bfd** command in the system view. The command output shows that the default static route has been bound to the BFD session.

Use the command output on Device A as an example.

```
[~DeviceA] display bfd session all  
(w): State in WTR  
(*): State is invalid  
-----  
Local Remote PeerIpAddr State Type InterfaceName  
-----  
10 20 2001:db8:1::2 Up S_IP_PEER -  
-----  
Total UP/DOWN Session Number : 1/0  
[~DeviceA] display current-configuration | include bfd  
bfd  
bfd aa bind peer-ipv6 2001:db8:1::2  
ipv6 route-static :: 0 2001:db8:1::2 track bfd-session aa
```

Check the IP routing table of Device A. The command output shows that the static route exists in the routing table.

```
[~DeviceA] display ipv6 routing-table  
Routing Table : _public_  
Destinations : 5 Routes : 5  
  
Destination : :: PrefixLength : 0  
NextHop : 2001:db8:1::2 Preference : 60  
Cost : 0 Protocol : Static  
RelayNextHop : :: TunnelID : 0x0  
Interface : GigabitEthernet1/0/0 Flags : RD  
  
Destination : 2001:db8:3::1 PrefixLength : 128  
NextHop : 2001:db8:3::1 Preference : 0  
Cost : 0 Protocol : Direct  
RelayNextHop : :: TunnelID : 0x0  
Interface : InLoopBack0 Flags : D  
  
Destination : 2001:db8:1:: PrefixLength : 64  
NextHop : 2001:db8:1::1 Preference : 0  
Cost : 0 Protocol : Direct  
RelayNextHop : :: TunnelID : 0x0  
Interface : GigabitEthernet1/0/0 Flags : D  
  
Destination : 2001:db8:1::1 PrefixLength : 128  
NextHop : 2001:db8:3::1 Preference : 0  
Cost : 0 Protocol : Direct  
RelayNextHop : :: TunnelID : 0x0  
Interface : GigabitEthernet1/0/0 Flags : D  
  
Destination : FE80:: PrefixLength : 10  
NextHop : :: Preference : 0  
Cost : 0 Protocol : Direct
```

```
RelayNextHop : ::           TunnelID : 0x0
Interface   : NULL0          Flags   : D
```

Run the **shutdown** command on GE 1/0/0 of Device B to simulate a link fault.

```
[~DeviceB] interface GigabitEthernet1/0/0
[~DeviceB-GigabitEthernet1/0/0] shutdown
```

Check the IP routing table of Device A. The command output shows that default route 0::0/0 does not exist. This is because the default static route has been bound to a BFD session. When BFD detects a link fault, BFD rapidly notifies that the bound static route becomes unavailable.

```
[~DeviceA] display ipv6 routing-table
Routing Table : _public_
Destinations : 1      Routes : 1

Destination : 2001:db8:3::1      PrefixLength : 128
NextHop    : 2001:db8:3::1      Preference  : 0
Cost       : 0                  Protocol   : Direct
RelayNextHop : ::              TunnelID   : 0x0
Interface   : InLoopBack0      Flags      : D
```

----End

```

Example for Configuring NQA for IPv6 Static Routes

NQA for IPv6 static routes can quickly detect network faults and control the advertisement of static routes.

Networking Requirements

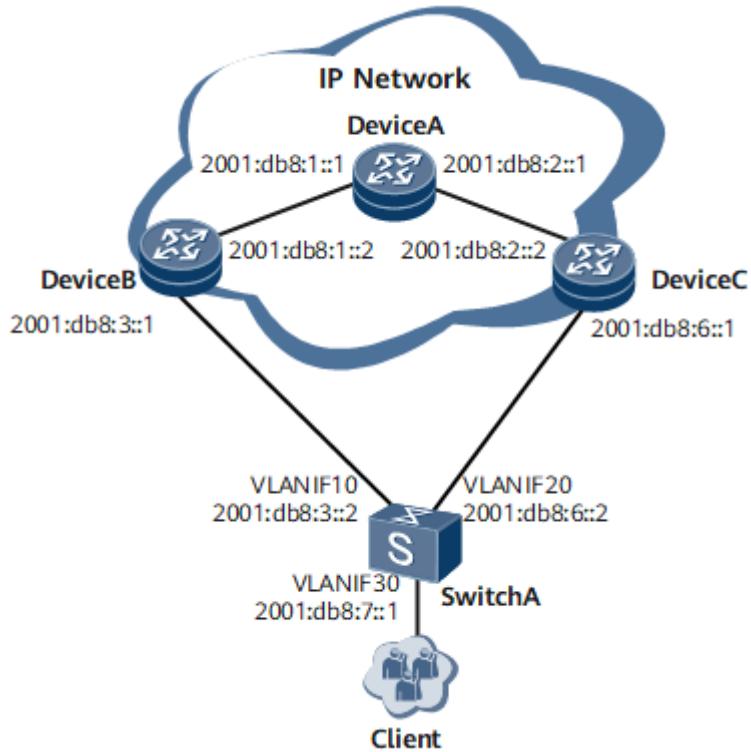

On a simple network or when the router cannot use a dynamic routing protocol to generate routes, you can configure static routes. Unlike dynamic routing protocols, static routes do not have a detection mechanism. If a link fails, a network administrator must manually delete the corresponding static route from the IPv6 routing table, which delays link switchovers and causes a lengthy service interruption.

Bidirectional Forwarding Detection (BFD) for static routes is adaptable to link changes but requires that both ends of a link support BFD. If either end of a link does not support BFD, configure NQA for IPv6 static routes. If an NQA test instance detects a link fault, it instructs the routing management module to delete the associated static route from the IPv6 routing table. Then traffic is switched to a backup route to prevent lengthy service interruptions.

In [Figure 1-56](#), backup links are deployed on the IP metropolitan area network (MAN).

- Static routes are configured on Device B and Device C. Device B is the master device, while Device C is the backup device.
- In most cases, traffic is transmitted over the primary link (Device B -> Switch A).
- If the primary link fails, traffic switches to the backup link (Device C -> Switch A).

Figure 1-56 NQA for IPv6 static routes

Device Name	Interface	IP Address
DeviceA	GE 1/0/0	2001:db8:1::1/64
	GE 2/0/3	2001:db8:2::1/64
DeviceB	GE 1/0/0	2001:db8:1::2/64
	GE 1/0/1	2001:db8:3::1/64
DeviceC	GE 1/0/0	2001:db8:6::1/64
	GE 2/0/3	2001:db8:2::2/64
SwitchA	VLANIF 10	2001:db8:3::2/64
	VLANIF 20	2001:db8:6::2/64
	VLANIF 30	2001:db8:7::1/64

NOTE

In this networking, Switch A provides access services for users. In actual networking, optical line terminals (OLTs), digital subscriber line access multiplexers (DSLAMs), multiservice access nodes (MSANs), or x digital subscriber lines (xDSLs) can be used for user access. The configurations on Device A, Device B, and Device C are the same.

Configuration Roadmap

The configuration roadmap is as follows:

1. Create an Internet Control Message Protocol (ICMP) NQA test instance to monitor the status of the primary link.
Create an ICMP NQA test instance on the NQA client Device B to test whether the primary link is running properly.
2. Configure static routes and associate the static route along the primary link with the ICMP NQA test instance.
Configure static routes on Device B and Device C, and associate the static route configured on Device B with the ICMP NQA test instance. If the ICMP NQA test instance detects a link fault, it instructs the routing management module to delete the associated static route from the IPv6 routing table.
3. Configure a dynamic routing protocol.
Configure a dynamic routing protocol on Device A, Device B, and Device C so that they can learn routes from one another.
4. Configure the dynamic routing protocol to import static routes and set a higher cost for the static route along the backup link than for the one along the primary link.
Configure the dynamic routing protocol on Device B and Device C to import static routes, and set a higher cost for the static route imported by Device C than for the one imported by Device B. This configuration allows Device A to preferentially select the link (Device B -> Switch A).

Data Preparation

To complete the configuration, you need the following data:

- Interface IPv6 addresses
- NQA item values (for details, see [Table 1-13](#))

Table 1-13 NQA item values

Item	Value
Administrator name	admin
Name of the test instance	test
Test type	ICMP
Destination address	2001:db8:3::2
Interval at which the NQA test automatically runs	3 seconds

- OSPFv3 backbone area (Area 0) of Device A, Device B, and Device C, and their router IDs (1.1.1.1, 2.2.2.2, and 3.3.3.3)

Procedure

Step 1 Configure interface IPv6 addresses. For configuration details, see [Configuration Files](#) in this section.

Step 2 Create an NQA test instance on Device B to test the link between Device B and Switch A.

```
<DeviceB> system-view
[~DeviceB] nqa test-instance admin test
[*DeviceB-nqa-admin-test] test-type icmp
[*DeviceB-nqa-admin-test] destination-address ipv6 2001:db8:3::2
[*DeviceB-nqa-admin-test] frequency 9
[*DeviceB-nqa-admin-test] interval seconds 3
[*DeviceB-nqa-admin-test] start now
[*DeviceB-nqa-admin-test] commit
[~DeviceB-nqa-admin-test] quit
```

Step 3 Configure IPv6 static routes.

```
# Configure an IPv6 static route on Device B and associate it with the NQA test instance.
```

```
[~DeviceB] ipv6 route-static 2001:db8:7:: 64 GigabitEthernet 1/0/1 2001:db8:3::2 track nqa admin test
[*DeviceB] commit
```

```
# Configure an IPv6 static route on Device C.
```

```
[*DeviceC] ipv6 route-static 2001:db8:7:: 64 GigabitEthernet 1/0/0 2001:db8:6::2
[*DeviceC] commit
```

NOTE

The next hop address of the IPv6 static route configured on the local end must be the link-local address of the peer end, which can be obtained using the **display ipv6 interface [interface-type interface-number]** command on the peer end.

Step 4 Configure a dynamic routing protocol on Device A, Device B, and Device C.

Configure OSPFv3 on Device A.

```
<DeviceA> system-view
[~DeviceA] interface GigabitEthernet 1/0/0
[~DeviceA-GigabitEthernet1/0/0] ospfv3 1 area 0.0.0.0
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
[~DeviceA] interface GigabitEthernet 2/0/3
[*DeviceA-GigabitEthernet2/0/3] ospfv3 1 area 0.0.0.0
[*DeviceA-GigabitEthernet2/0/3] commit
[~DeviceA-GigabitEthernet2/0/3] quit
```

Configure OSPFv3 on Device B.

```
[~DeviceB] interface GigabitEthernet 1/0/0
[~DeviceB-GigabitEthernet1/0/0] ospfv3 1 area 0.0.0.0
[*DeviceB-GigabitEthernet1/0/0] commit
[~DeviceB-GigabitEthernet1/0/0] quit
```

Configure OSPFv3 on Device C.

```
[~DeviceC] interface GigabitEthernet 2/0/3
[~DeviceC-GigabitEthernet2/0/3] ospfv3 1 area 0.0.0.0
[*DeviceC-GigabitEthernet2/0/3] commit
[~DeviceC-GigabitEthernet2/0/3] quit
```

Step 5 Configure OSPFv3 on Device B and Device C to import static routes.

Configure OSPFv3 on Device B to import a static route and set the cost to 10 for the static route.

```
[~DeviceB] ospfv3 1
[*DeviceB-ospfv3-1] import-route static cost 10
[*DeviceB-ospfv3-1] commit
[~DeviceB-ospfv3-1] quit
```

Configure OSPFv3 on Device C to import a static route and set the cost to 20 for the static route.

```
[*DeviceC] ospfv3 1
[*DeviceC-ospfv3-1] import-route static cost 20
[*DeviceC-ospfv3-1] commit
[~DeviceC-ospfv3-1] quit
```

Step 6 Verify the configuration.

After the configuration is complete, run the **display current-configuration | include nqa** command on Device B in the system view. The command output shows that the IPv6 static route has been associated with the NQA test instance. Run the **display nqa results** command. The command output shows that an NQA test instance has been created.

Display configurations of NQA for IPv6 static routes.

```
[~DeviceB] display current-configuration | include nqa
ipv6 route-static 2001:db8:7:: 64 GigabitEthernet1/0/1 2001:db8:3::2 track nqa admin test
nqa test-instance admin test
```

Display NQA test results.

```
[~DeviceB] display nqa results test-instance admin test
NQA entry(admin, test) : testflag is active ,testtype is icmp
1 . Test 359 result    The test is finished
Send operation times: 3          Receive response times: 3
Completion:success           RTD OverThresholds number:0
Attempts number:1            Drop operation number:0
```

```
Disconnect operation number:0      Operation timeout number:0
System busy operation number:0    Connection fail number:0
Operation sequence errors number:0 RTT Stats errors number:0
Destination ip address:2001:db8:3::2
Min/Max/Average Completion Time: 1/3/2
Sum/Square-Sum Completion Time: 7/19
Last Good Probe Time: 2012-11-14 12:15:22.3
Lost packet ratio: 0 %
```

The command output shows "Lost packet ratio 0 %," indicating that the link is running properly.

Display the routing table on Device B.

```
[~DeviceB] display ipv6 routing-table 2001:db8:7::
Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:7::          PrefixLength : 64
NextHop    : 2001:db8:3::2        Preference   : 60
Cost       : 0                   Protocol     : Static
RelayNextHop : ::                TunnelID    : 0x0
Interface   : GigabitEthernet1/0/1 Flags       : D
```

The command output shows that the static route exists in the routing table.

Display the routing table on Device A.

```
[~DeviceA] display ipv6 routing-table 2001:db8:7::
Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:7::          PrefixLength : 64
NextHop    : FE80::2200:10FF:FE03:0  Preference   : 150
Cost       : 10                  Protocol     : OSPFv3ASE
RelayNextHop : ::                TunnelID    : 0x0
Interface   : GigabitEthernet1/0/0 Flags       : D
```

The command output shows that a route to 2001:db8:7::1/128 exists in the routing table. The outbound interface of the route is GE 1/0/0 and the cost is 10. Traffic is preferentially transmitted along the link Device B -> Switch A.

Shut down GE 1/0/1 on Device B to simulate a link fault.

```
[~DeviceB] interface GigabitEthernet 1/0/1
[*DeviceB-GigabitEthernet1/0/1] shutdown
[*DeviceB-GigabitEthernet1/0/1] commit
[~DeviceB-GigabitEthernet1/0/1] quit
```

Display NQA test results.

```
[~DeviceB] display nqa results test-instance admin test
NQA entry(admin, test) : testflag is active ,testtype is icmp
1 . Test 1156 result  The test is finished
Send operation times: 3      Receive response times: 0
Completion:failed          RTD OverThresholds number:0
Attempts number:1           Drop operation number:0
Disconnect operation number:0 Operation timeout number:3
System busy operation number:0 Connection fail number:0
Operation sequence errors number:0 RTT Stats errors number:0
Destination ip address:2001:db8:3::2
Min/Max/Average Completion Time: 0/0/0
Sum/Square-Sum Completion Time: 0/0
Last Good Probe Time: 0000-00-00 00:00:00.0
Lost packet ratio: 100 %
```

The command output shows "Completion:failed" and "Lost packet ratio is 100 %," indicating that the link is faulty.

Display the routing table on Device B.

```
[~DeviceB] display ipv6 routing-table 2001:db8:7::  
Routing Table : _public_  
Summary Count : 1  
  
Destination : 2001:db8:7:: PrefixLength : 64  
NextHop : FE80::3A00:10FF:FE03:0 Cost : 20 Preference : 150  
Protocol : OSPFv3ASE  
RelayNextHop : :: TunnelID : 0x0  
Interface : GigabitEthernet1/0/0 Flags : D
```

The command output shows that the static route has been deleted and that the route has become an OSPFv3 route learned from Device A.

Display the routing table on Device A.

```
[~DeviceA] display ipv6 routing-table 2001:db8:7::  
Routing Table : _public_  
Summary Count : 1  
  
Destination : 2001:db8:7:: PrefixLength : 64  
NextHop : FE80::3A00:10FF:FE03:107 Cost : 20 Preference : 150  
Protocol : OSPFv3ASE  
RelayNextHop : :: TunnelID : 0x0  
Interface : GigabitEthernet2/0/3 Flags : D
```

The static route has been associated with the NQA test instance on Device B. If NQA detects a link fault, it rapidly notifies Device B that the associated static route is unavailable. Device A cannot learn the route to 2001:db8:7::/64 from Device B. However, Device A can learn the route to 2001:db8:7::/64 from Device C. The route's outbound interface is GE 2/0/3, and the cost is 20. Traffic switches to the link Device C -> Switch A.

----End

Example for Configuring NQA Group for IPv6 Static Route

NQA group for IPv6 static route allows an NQA group to be associated with multiple NQA test instances to monitor multiple links, rapidly detect network faults, and control advertisement of IPv6 static routes, thereby implementing service switching.

Networking Requirements

NQA group for IPv6 static route monitors the link status of an IPv6 static route through association between the static route and an NQA group that consists of multiple NQA test instances. The RM module determines whether the IPv6 static route is active based on the test result of the NQA group. If the IPv6 static route is inactive, the RM module deletes it from the IP routing table and selects an available backup link for data forwarding, which prevents lengthy service interruptions.

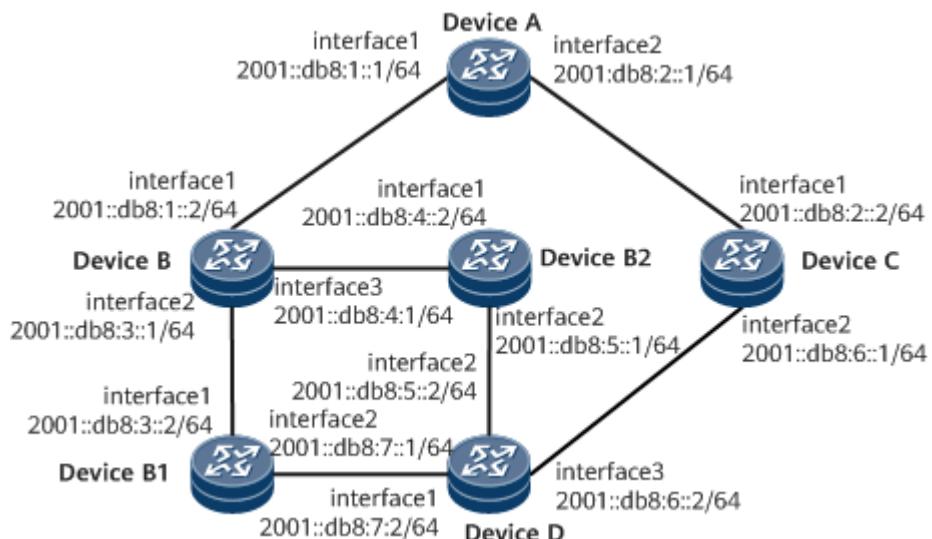

Figure 1-57 shows a network with redundant links.

- BGP peer relationships are established between Device A and Device B and between Device A and Device C.
- On Device B and Device C, default static routes are configured and imported into BGP, and different PrefVal values are configured so that Device B and Device C function as the master device and backup device, respectively.
- Device B and Device D are connected through two links by way of Device B1 and Device B2.
- In normal cases, traffic is transmitted along the primary link (Device B -> Device D).
- If the primary link fails (the NQA group bound to the IPv6 default static route of Device B considers the IPv6 static route inactive when monitoring the two links from Device B to Device D), traffic is switched to the backup link (Device C -> Device D).

Figure 1-57 Network diagram of NQA group for IPv6 static route

NOTE

In this example, interface1, interface2, and interface3 represent GE 1/0/0, GE 1/0/1, and GE 1/0/2, respectively.

Configuration Roadmap

The configuration roadmap is as follows:

1. Create NQA test instances of the ICMP type to detect faults on the primary link.

Create two NQA test instances of the ICMP type between Device B and Device B1 and between Device B and Device B2 to correspond to the two links between Device B and Device D and to check whether the primary link (Device B -> Device D) is running properly.
2. Create an NQA group.

Bind the two NQA test instances of the ICMP type to the NQA group.
3. Configure static routes and associate the static route along the primary link with the NQA group.

Configure IPv6 static routes to loopback0 interfaces between Device A and Device B, and between Device A and Device C. Configure default IPv6 static routes on Device B and Device C. Associate the IPv6 static route configured on Device B with the NQA group, which collects the detection results of two NQA test instances to determine its status. When the NQA group goes down, the device determines that the current link is faulty and instructs the RM module to delete the IPv6 static route from the IP routing table.
4. Configure BGP.

Configure BGP on Device A, Device B, and Device C so that they can learn routes from each other.
5. Configure BGP to import IPv6 static routes and set a larger PrefVal value for the primary link.

Configure BGP on Device B and Device C to import IPv6 static routes, and set a larger PrefVal value for the IPv6 static route imported by Device B. When Device A learns routes to the same destination from Device B and Device C, it preferentially selects the link (Device B -> Device D), which has a larger PrefVal value.

Data Preparation

To complete the configuration, you need the following data:

- IP address of each interface
- NQA-related configurations (for details, see [Table 1-14](#))

Table 1-14 NQA parameter values

Item	Value
Administrator name	user1, user2
Test instance name	test1, test2
Test type	ICMP
Destination address	2001::db8:3::2/64, 2001::db8:4::2/64
Test interval	10s
Number of probes	2
Interval at which packets are sent	5s

Item	Value
Timeout period	4s

- Operation type between test instances in the NQA group: OR
- BGP AS numbers (the same) and router IDs of Device A, Device B, and Device C (1.1.1.1, 2.2.2.2, and 3.3.3.3, respectively)

Procedure

Step 1 Configure IP addresses. For details, see [Configuration Files](#).

Step 2 On Device B, configure two NQA test instances of the ICMP type between Device B and Device B1 and between Device B and Device B2.

```
<DeviceB> system-view
[~DeviceB] nqa test-instance user1 test1
[*DeviceB-nqa-user1-test1] test-type icmp
[*DeviceB-nqa-user1-test1] destination-address ipv6 2001:db8:3::2
[*DeviceB-nqa-user1-test1] frequency 10
[*DeviceB-nqa-user1-test1] probe-count 2
[*DeviceB-nqa-user1-test1] interval seconds 5
[*DeviceB-nqa-user1-test1] timeout 4
[*DeviceB-nqa-user1-test1] start now
[*DeviceB-nqa-user1-test1] commit
[~DeviceB-nqa-user1-test1] quit
[~DeviceB] nqa test-instance user2 test2
[*DeviceB-nqa-user2-test2] test-type icmp
[*DeviceB-nqa-user2-test2] destination-address ipv6 2001:db8:4::2
[*DeviceB-nqa-user2-test2] frequency 10
[*DeviceB-nqa-user2-test2] probe-count 2
[*DeviceB-nqa-user2-test2] interval seconds 5
[*DeviceB-nqa-user2-test2] timeout 4
[*DeviceB-nqa-user2-test2] start now
[*DeviceB-nqa-user2-test2] commit
[~DeviceB-nqa-user2-test2] quit
```

Step 3 Create an NQA group and bind the two NQA test instances of the ICMP type to the group.

```
[~DeviceB] nqa group group1
[*DeviceB-nqa-group-group1] nqa test-instance user1 test1
[*DeviceB-nqa-group-group1] nqa test-instance user2 test2
[*DeviceB-nqa-group-group1] operator or
[*DeviceB-nqa-group-group1] commit
[~DeviceB-nqa-group-group1] quit
```

Step 4 Configure static routes.

```
# Configure static routes to loopback interfaces between Device A and Device B,
and between Device A and Device C.
```

```
[~DeviceA] ipv6 route-static 2::2 128 GigabitEthernet 1/0/0 2001:db8:1::2
[~DeviceA] ipv6 route-static 3::3 128 GigabitEthernet 1/0/1 2001:db8:2::2
[*DeviceA] commit
```

```
# Configure a static route to the loopback interface of Device A on Device B.
```

```
[~DeviceB] ipv6 route-static 1::1 128 GigabitEthernet 1/0/0 2001:db8:1::1
[*DeviceB] commit
```

```
# Configure a static route to the loopback interface of Device A on Device C.
```

```
[~DeviceC] ipv6 route-static 1::1 128 GigabitEthernet 1/0/1 2001:db8:2::1
[*DeviceC] commit
```

Configure a default static route on Device B and associate it with the NQA group.

```
[*DeviceB] ipv6 route-static :: 128 NULL0 track nqa-group group1  
[*DeviceB] commit
```

Configure a default static route on Device C.

```
[*DeviceC] ipv6 route-static :: 128 NULL0  
[*DeviceC] commit
```

Step 5 Configure BGP on Device A, Device B, and Device C.

Configure BGP on Device A.

```
[~DeviceA] bgp 100  
[*DeviceA-bgp] peer 2::2 as-number 100  
[*DeviceA-bgp] peer 2::2 connect-interface LoopBack0  
[*DeviceA-bgp] peer 3::3 as-number 100  
[*DeviceA-bgp] peer 3::3 connect-interface LoopBack0  
[*DeviceA-bgp] quit  
[*DeviceA] commit
```

Configure BGP on Device B.

```
[~DeviceB] bgp 100  
[*DeviceB-bgp] peer 1::1 as-number 100  
[*DeviceB-bgp] peer 1::1 connect-interface LoopBack0  
[*DeviceB-bgp] quit  
[*DeviceB] commit
```

Configure BGP on Device C.

```
[~DeviceC] bgp 100  
[*DeviceC-bgp] peer 1::1 as-number 100  
[*DeviceC-bgp] peer 1::1 connect-interface LoopBack0  
[*DeviceC-bgp] quit  
[*DeviceC] commit
```

Step 6 Configure BGP on Device B and Device C to import IPv6 static routes, and set a larger PrefVal value for the primary link.

Configure BGP on Device B to import IPv6 static routes, and set the PrefVal value to 200.

```
[~DeviceB] bgp 100  
[*DeviceB-bgp] import-route static  
[*DeviceB-bgp] ipv6-family unicast  
[*DeviceB-bgp-af-ipv6] peer 1::1 preferred-value 200  
[*DeviceB-bgp-af-ipv6] commit  
[~DeviceB-bgp-af-ipv6] quit  
[~DeviceB-bgp] quit
```

Configure BGP on Device C to import IPv6 static routes, and set the PrefVal value to 100.

```
[~DeviceC] bgp 100  
[*DeviceC-bgp] import-route static  
[*DeviceC-bgp] ipv6-family unicast  
[*DeviceC-bgp-af-ipv6] peer 1::1 preferred-value 100  
[*DeviceC-bgp-af-ipv6] commit  
[~DeviceC-bgp-af-ipv6] quit  
[~DeviceC-bgp] quit
```

Step 7 Verify the configuration.

Check the results of the two NQA test instances on Device B.

```
[~DeviceB] display nqa results test-instance user1 test1
```

```
NQA entry(user1, test1) :testflag is inactive ,testtype is icmp
1 . Test 1 result The test is finished
Send operation times: 3          Receive response times: 3
Completion:success           RTD OverThresholds number:0
Attempts number:1              Drop operation number:0
Disconnect operation number:0   Operation timeout number:0
System busy operation number:0  Connection fail number:0
Operation sequence errors number:0  RTT Status errors number:0
Destination ip address:172.16.1.2
Min/Max/Average Completion Time: 11/185/69
Sum/Square-Sum Completion Time: 207/34467
Last Good Probe Time: 2022-09-24 15:08:38.6
Lost packet ratio: 0 %
[~DeviceB] display nqa results test-instance user2 test2
NQA entry(user2, test2) :testflag is inactive ,testtype is icmp
1 . Test 1 result The test is finished
Send operation times: 3          Receive response times: 3
Completion:success           RTD OverThresholds number:0
Attempts number:1              Drop operation number:0
Disconnect operation number:0   Operation timeout number:0
System busy operation number:0  Connection fail number:0
Operation sequence errors number:0  RTT Status errors number:0
Destination ip address:172.16.2.2
Min/Max/Average Completion Time: 9/16/11
Sum/Square-Sum Completion Time: 34/418
Last Good Probe Time: 2022-09-24 15:08:50.3
Lost packet ratio: 0 %
```

The command output shows "Lost packet ratio 0 %," indicating that the link is running properly.

Check the test result of the NQA group on Device B.

```
[~DeviceB] display nqa group
NQA-group information:
-----
NQA-group group1
Status: UP      Operator: OR
-----
Admin-name        Test-name        Status
-----
user1            test1           UP
user2            test2           UP
```

Check the routing table of Device A.

```
[~DeviceA] display ipv6 routing-table | include IBGP
Routing Table : _public_
Summary Count : 1

Destination : ::          PrefixLength : 128
NextHop    : 2::2          Preference  : 255
Cost       : 0             Protocol   : IBGP
RelayNextHop : ::          TunnelID   : 0x0
Interface   : GigabitEthernet1/0/0     Flags      : RD
```

The command output shows that the next hop used to forward user traffic on Device A is Device B, indicating that user traffic is transmitted along the primary link.

Shut down GigabitEthernet 1/0/1 on Device B to simulate a link fault.

```
[~DeviceB] interface GigabitEthernet 1/0/1
[~DeviceB-GigabitEthernet1/0/1] shutdown
[*DeviceB-GigabitEthernet1/0/1] commit
[~DeviceB] quit
```

Check the NQA test result.

```
[~DeviceB] display nqa results test-instance user1 test1
NQA entry(user1, test1) :testflag is inactive ,testtype is icmp
2 . Test 2 result The test is finished
Send operation times: 3           Receive response times: 0
Completion:failed           RTD OverThresholds number:0
Attempts number:1           Drop operation number:0
Disconnect operation number:0     Operation timeout number:3
System busy operation number:0    Connection fail number:0
Operation sequence errors number:0   RTT Status errors number:0
Destination ip address:172.16.1.2
Min/Max/Average Completion Time: 0/0/0
Sum/Square-Sum Completion Time: 0/0
Last Good Probe Time: 0000-00-00 00:00:00.0
Lost packet ratio: 100 %
```

"Completion:failed" and "Lost packet ratio: 100%" are displayed, indicating that the link where GigabitEthernet 1/0/1 resides is faulty.

Check the test result of the NQA group on Device B.

```
[~DeviceB] display nqa group
NQA-group information:
-----
NQA-group group1
Status: UP      Operator: OR
-----
Admin-name          Test-name        Status
-----
user1              test1           DOWN
user2              test2           UP
```

The command output shows that the status of the NQA group remains UP.

Check the routing table of Device A.

```
[~DeviceA] display ipv6 routing-table | include IBGP
Routing Table : _public_
Summary Count : 1
-----
Destination : ::          PrefixLength : 128
NextHop    : 2::2          Preference  : 255
Cost       : 0             Protocol   : IBGP
RelayNextHop : ::          TunnelID   : 0x0
Interface  : GigabitEthernet1/0/0   Flags     : RD
```

The operation type between test instances in the NQA group is OR. Therefore, the status of the NQA group remains UP.

Shut down GigabitEthernet 1/0/2 on Device B to simulate a link fault.

```
[~DeviceB] interface GigabitEthernet 1/0/2
[~DeviceB-GigabitEthernet1/0/2] shutdown
[*DeviceB-GigabitEthernet1/0/2] commit
[~DeviceB] quit
```

Check the NQA test result.

```
[~DeviceB] display nqa results test-instance user2 test2
NQA entry(user2, test2) : testflag is active ,testtype is icmp
1 . Test 186 result The test is finished
Send operation times: 2           Receive response times: 0
Completion:failed           RTD OverThresholds number:0
Attempts number:1           Drop operation number:0
Disconnect operation number:0     Operation timeout number:2
System busy operation number:0    Connection fail number:0
Operation sequence errors number:0   RTT Stats errors number:0
Destination ip address:172.16.2.2
Min/Max/Average Completion Time: 0/0/0
Sum/Square-Sum Completion Time: 0/0
```

```
Last Good Probe Time: 0000-00-00 00:00:00.0
Lost packet ratio: 100 %
```

"Completion:failed" and "Lost packet ratio: 100%" are displayed, indicating that the link where GigabitEthernet 1/0/2 resides is faulty.

Check the test result of the NQA group on Device B.

```
[~DeviceB] display nqa group
NQA-group information:
-----
NQA-group group1
Status: DOWN      Operator: OR
-----
Admin-name          Test-name        Status
-----
user1              test1           DOWN
user2              test2           DOWN
```

The command output shows that the status of the NQA group changes to DOWN.

Check the routing table of Device A.

```
[~DeviceA] display ipv6 routing-table | include IBGP
Routing Table : _public_
Summary Count : 1
-----
Destination : ::          PrefixLength : 128
NextHop    : 3::3          Preference   : 255
Cost       : 0             Protocol     : IBGP
RelayNextHop : ::          TunnelID    : 0x0
Interface   : GigabitEthernet1/0/1   Flags       : RD
```

The command output shows that the next hop used to forward user traffic on Device A changes to Device C, indicating that the traffic is switched to the backup link.

The NQA group on Device B is associated with the IPv6 static route. When the NQA group detects that both links from Device B to Device D fail, the NQA group goes down and rapidly notifies Device B that the associated IPv6 static route is unavailable. Service traffic is then switched to the backup link.

----End

Example for Configuring FRR for IPv6 Static Routes on the Public Network

FRR for IPv6 static routes on the public network can fast detect link failures.

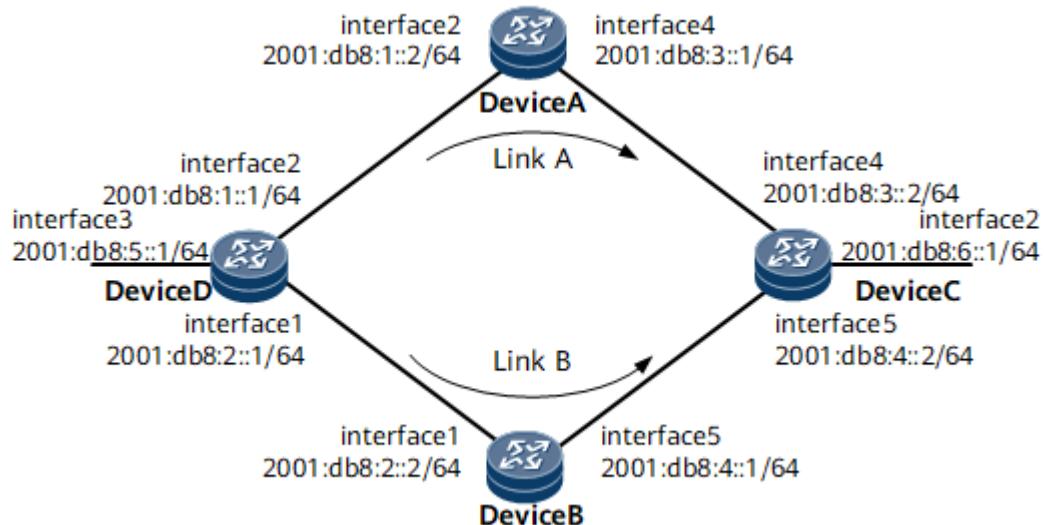

Networking Requirements

On the network shown in [Figure 1-58](#), it is required that two IPv6 static routes with Device A and Device B as the next hops be configured on Device D and that Link B function as the backup of Link A. If Link A fails, traffic is switched to the Link B immediately.

Figure 1-58 Networking for configuring FRR for IPv6 static routes on the public network

In this example, interface1, interface2, interface3, interface4, and interface5 represent GE 1/0/1, GE 1/0/2, GE 1/0/3, GE 2/0/3, and GE 3/0/3, respectively.

Precautions

When configuring FRR for IPv6 static routes on the public network, ensure that there are at least two IPv6 static routes to the same destination address.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure two IPv6 static routes with Device A and Device B as the next hops on Device D.
2. On Device D, set a higher priority for Link A to ensure that Link A becomes the primary link.
3. Enable FRR for IPv6 static routes on Device D, and check the backup outbound interface and the backup next hop.
4. Configure static BFD for IPv6 static routes to speed up fault detection.

NOTE

To speed up fault detection, configure dynamic or static BFD for IPv6 static routes. In this example, static BFD for IPv6 static routes is used. This is because it is more commonly used on the live network.

5. Disable FRR for IPv6 static routes, and check the backup outbound interface and the backup next hop.

Data Preparation

To complete the configuration, you need preference values of IPv6 static routes.

Procedure

- Step 1** Configure an IP address for each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure IPv6 static routes.

On Device A, configure IPv6 static routes.

```
[~DeviceA] ipv6 route-static 2001:db8:5:: 64 GigabitEthernet1/0/2 2001:db8:1::1
[*DeviceA] ipv6 route-static 2001:db8:6:: 64 GigabitEthernet2/0/3 2001:db8:3::2
[*DeviceA] commit
```

On Device B, configure static routes.

```
[~DeviceB] ipv6 route-static 2001:db8:5:: 64 GigabitEthernet1/0/1 2001:db8:2::1
[*DeviceB] ipv6 route-static 2001:db8:6:: 64 GigabitEthernet3/0/3 2001:db8:4::2
[*DeviceB] commit
```

On Device C, configure IPv6 static routes.

```
[~DeviceC] ipv6 route-static 2001:db8:5:: 64 GigabitEthernet2/0/3 2001:db8:3::1
[*DeviceC] ipv6 route-static 2001:db8:5:: 64 GigabitEthernet3/0/3 2001:db8:4::1
[*DeviceC] ipv6 route-static 2001:db8:1:: 64 GigabitEthernet2/0/3 2001:db8:3::1
[*DeviceC] ipv6 route-static 2001:db8:2:: 64 GigabitEthernet3/0/3 2001:db8:4::1
[*DeviceC] commit
```

On Device D, configure IPv6 static routes.

```
[~DeviceD] ipv6 route-static 2001:db8:6:: 64 GigabitEthernet1/0/2 2001:db8:1::2
[*DeviceD] ipv6 route-static 2001:db8:6:: 64 GigabitEthernet1/0/1 2001:db8:2::2
[*DeviceD] ipv6 route-static 2001:db8:3:: 64 GigabitEthernet1/0/2 2001:db8:1::2
[*DeviceD] ipv6 route-static 2001:db8:4:: 64 GigabitEthernet1/0/1 2001:db8:2::2
[*DeviceD] commit
[~DeviceD] quit
```

Check the IP routing table of Device D. The following command output shows that load balancing is performed between the two IPv6 static routes.

```
<DeviceD> display ipv6 routing-table
Routing Table : _public_

Step 3 Change the priorities of the IPv6 static routes.

Change the preference value of the IPv6 static route on Device D.

```
<DeviceD> system-view
[~DeviceD] ipv6 route-static 2001:db8:6:: 64 GigabitEthernet1/0/2 2001:db8:1::2 preference 40
[*DeviceD] commit
[~DeviceD] quit
```

Check the routing table of Device D. The following command output shows that the preference value of the IPv6 static route has been changed.

```
<DeviceD> display ipv6 routing-table
Routing Table : _public_
Destinations : 13      Routes : 13

Destination : ::1          PrefixLength : 128
```

NextHop : ::1	Preference : 0
Cost : 0	Protocol : Direct
RelayNextHop : ::	TunnelID : 0x0

Interface : NULL0	Flags : D

Step 4 Enable FRR for IPv6 static routes.

Enable FRR for static route on Device D.

```
<DeviceD> system-view
[~DeviceD] ipv6 route-static frr
[*DeviceD] commit
[~DeviceD] quit
```

Check the backup outbound interface and the backup next hop on Device D.

```
<DeviceD> display ipv6 routing-table 2001:db8:6:: verbose
Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:6:: PrefixLength : 64
NextHop : 2001:db8:1::2 Preference : 40
Neighbour : :: ProcessID : 0
Label : NULL Protocol : Static
State : Active Adv Cost : 0

Priority : medium Age : 28sec
IndirectID : 0xFC000105
RelayNextHop : :: TunnelID : 0x0
Interface : GigabitEthernet1/0/2 Flags : D
BkNextHop : 2001:db8:2::2 BklInterface : GigabitEthernet1/0/1
BkLabel : NULL BkTunnelID : 0x0
BkPETunnelID : 0x0 BkIndirectID : 0xFC0001
```

Step 5 Configure static BFD for IPv6 static routes.

- Configure a BFD session.

On Device D, configure a BFD session between Device D and Device C.

```
<DeviceD> system-view
[~DeviceD] bfd
[*DeviceD-bfd] quit
[*DeviceD] bfd aa bind peer-ipv6 2001:db8:3::2 source-ipv6 2001:db8:1::1
[*DeviceD-bfd-session-aa] discriminator local 10
[*DeviceD-bfd-session-aa] discriminator remote 20
[*DeviceD-bfd-session-aa] commit
[~DeviceD-bfd-session-aa] quit
```

On Device C, configure a BFD session between Device C and Device D.

```
<DeviceC> system-view
[~DeviceC] bfd
[*DeviceC-bfd] quit
[*DeviceC] bfd ab bind peer-ipv6 2001:db8:1::1 source-ipv6 2001:db8:3::2
[*DeviceC-bfd-session-ab] discriminator local 20
[*DeviceC-bfd-session-ab] discriminator remote 10
[*DeviceC-bfd-session-ab] commit
[~DeviceC-bfd-session-ab] quit
```

- Configure a static route and bind it to the BFD session.

On Device D, configure a static route and bind it to the BFD session named **aa**.

```
[~DeviceD] ipv6 route-static 2001:db8:6:: 64 GigabitEthernet1/0/2 2001:db8:1::2 preference 40
track bfd-session aa
```

Step 6 Simulate a fault on Link A.

```
[~DeviceD] interface GigabitEthernet1/0/2
[~DeviceD-GigabitEthernet1/0/2] shutdown
[~DeviceD-GigabitEthernet1/0/2] commit
[~DeviceD-GigabitEthernet1/0/2] quit
[~DeviceD] quit
```

Check the routes to 2001:db8:6::/64 on Device D.

```
<DeviceD> display ipv6 routing-table 2001:db8:6:: verbose
Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:6:: PrefixLength : 64
NextHop    : 2001:db8:2::2 Preference  : 60
Neighbour   : :: ProcessID   : 0
Label       : NULL Protocol    : Static

1.1.4 OSPF Configuration

1.1.4.1 OSPF Description

1.1.4.1.1 Overview of OSPF

Definition

Open Shortest Path First (OSPF) is a link-state Interior Gateway Protocol (IGP) developed by the Internet Engineering Task Force (IETF).

OSPF version 2 (OSPFv2) is intended for IPv4. OSPF version 3 (OSPFv3) is intended for IPv6.

NOTE

In this document, OSPF refers to OSPFv2, unless otherwise stated.

Purpose

Before the emergence of OSPF, the Routing Information Protocol (RIP) was widely used as an IGP on networks. RIP is a distance-vector routing protocol. Due to its slow convergence, routing loops, and poor scalability, RIP is gradually being replaced with OSPF.

Typical IGPs include RIP, OSPF, and Intermediate System to Intermediate System (IS-IS). **Table 1-15** describes differences among the three typical IGPs.

Table 1-15 Differences among RIP, OSPF, and IS-IS

Item	RIP	OSPF	IS-IS
Protocol type	IP layer protocol	IP layer protocol	Link layer protocol
Application scope	Applies to small networks with simple architectures, such as campus networks.	Applies to medium-sized networks with several hundred routers supported, such as enterprise networks.	Applies to large networks, such as Internet service provider (ISP) networks.

Item	RIP	OSPF	IS-IS
Routing algorithm	Uses a distance-vector algorithm and exchanges routing information over the User Datagram Protocol (UDP).	Uses the shortest path first (SPF) algorithm to generate a shortest path tree (SPT) based on the network topology, calculates shortest paths to all destinations, and exchanges routing information over IP.	Uses the SPF algorithm to generate an SPT based on the network topology, calculates shortest paths to all destinations, and exchanges routing information over IP. The SPF algorithm runs separately in Level-1 and Level-2 databases.
Route convergence speed	Slow	Less than 1 second	Less than 1 second
Scalability	Not supported	Supported by partitioning a network into areas	Supported by defining router levels

Benefits

OSPF offers the following benefits:

- Wide application scope: OSPF applies to medium-sized networks with several hundred routers, such as enterprise networks.
- Network masks: OSPF packets can carry masks, and therefore the packet length is not limited by natural IP masks. OSPF can process variable length subnet masks (VLSMs).
- Fast convergence: When the network topology changes, OSPF immediately sends link state update (LSU) packets to synchronize the changes to the link state databases (LSDBs) of all routers in the same autonomous system (AS).
- Loop-free routing: OSPF uses the SPF algorithm to calculate loop-free routes based on the collected link status.
- Area partitioning: OSPF allows an AS to be partitioned into areas, which simplifies management. Routing information transmitted between areas is summarized, which reduces network bandwidth consumption.
- Equal-cost routes: OSPF supports multiple equal-cost routes to the same destination.
- Hierarchical routing: OSPF uses intra-area routes, inter-area routes, Type 1 external routes, and Type 2 external routes, which are listed in descending order of priority.
- Authentication: OSPF supports area-based and interface-based packet authentication, which ensures packet exchange security.

- Multicast: OSPF uses multicast addresses to send packets on certain types of links, which minimizes the impact on other devices.

1.1.4.1.2 Understanding OSPF

Basic Concepts of OSPF

Router ID

A router ID is a 32-bit unsigned integer and uniquely identifies a router in an AS. A router ID must exist on a router if OSPF needs to be run on it.

A router ID can be manually configured or automatically selected by the router.

If a router ID is specified when an OSPF process is created in the system view, the configured router ID is used. If no router ID is specified when an OSPF process is created, the OSPF process uses the router ID in RM. For details about router ID selection rules in RM, see the **router id** command in the system view. In any of the following situations, OSPF router ID re-selection is performed:

- After you run this command to configure a new OSPF router ID, the OSPF process automatically restarts.
- No router ID is specified for an OSPF process, the router ID in RM changes, and the OSPF process is restarted using the **reset ospf process** command.
- If the self-healing function is enabled for OSPF router ID conflicts and an OSPF router ID conflict occurs on the network, a new OSPF router ID is selected and the OSPF process is automatically restarted. If no router ID is specified when an OSPF process is created and the device restarts in CFG mode, the router ID in the RM module when the OSPF process is created is used as the OSPF router ID after the restart. Therefore, you are advised to manually specify a router ID when creating the OSPF process.

Areas

When a large number of routers run OSPF, link state databases (LSDBs) become very large and require a large amount of storage space. Large LSDBs also complicate shortest path first (SPF) computation and overload the routers. As the network scale expands, there is an increasing probability that the network topology changes, causing the network to change continuously. In this case, a large number of OSPF packets are transmitted on the network, leading to a decrease in bandwidth utilization efficiency. In addition, each time the topology changes, all routers on the network must recalculate routes.

OSPF prevents frequent LSDB updates and improves network utilization by partitioning an AS into different areas. routers can be logically allocated to different groups (areas), and each group is identified by an area ID. A router, not a link, resides at the border of an area. A network segment or link can belong to only one area. An area must be specified for each OSPF interface.

OSPF areas include common areas, stub areas, and not-so-stubby areas (NSSAs). **Table 1-16** describes these OSPF areas.

Table 1-16 Area types

Area Type	Function	Description
Common area	<p>By default, OSPF areas are defined as common areas. Common areas include:</p> <ul style="list-style-type: none"> Standard area is the most prevalent area and transmits intra-area, inter-area, and external routes. Backbone area connects to all other OSPF areas and is usually represented by Area 0. The backbone area is responsible for inter-area routing. Routing information between non-backbone areas must be forwarded through the backbone area. 	<ul style="list-style-type: none"> The backbone area must have all its devices connected. All non-backbone areas must remain connected to the backbone area.
Stub area	<p>A stub area is a non-backbone area with only one area border router (ABR) and generally resides at the border of an AS. The ABR in a stub area does not transmit received AS external routes, which significantly decreases the number of entries in the routing table on the router and the amount of routing information to be transmitted. To ensure the reachability of AS external routes, the ABR in the stub area generates a default route and advertises the route to non-ABRs in the stub area.</p> <p>A totally stub area allows only intra-area routes and ABR-advertised Type 3 default routes to be advertised within the area and does not allow AS external routes or inter-area routes to be advertised.</p>	<ul style="list-style-type: none"> The backbone area cannot be configured as a stub area. An autonomous system boundary router (ASBR) cannot exist in a stub area. Therefore, AS external routes cannot be advertised within the stub area. A virtual link cannot pass through a stub area.
NSSA	<p>An NSSA is similar to a stub area. An NSSA does not support Type 5 LSAs but can import AS-external routes. Type 7 LSAs carrying information about the AS-external routes are generated by ASBRs in the NSSA and are advertised only within the NSSA. When the Type 7 LSAs reach an ABR in the NSSA, the ABR translates the Type 7 LSAs into Type 5 LSAs and floods them to the entire OSPF domain.</p> <p>A totally NSSA allows only intra-area routes to be advertised within the area. AS external routes or inter-area routes cannot be advertised in a totally NSSA.</p>	<ul style="list-style-type: none"> An ASBR in an NSSA advertises Type 7 LSA default routes within the NSSA. All inter-area routes must be advertised by ABRs. A virtual link cannot pass through an NSSA.

Router Types

Routers are classified by location in an AS. [Figure 1-59](#) and [Table 1-17](#) show the classification.

Figure 1-59 Router types

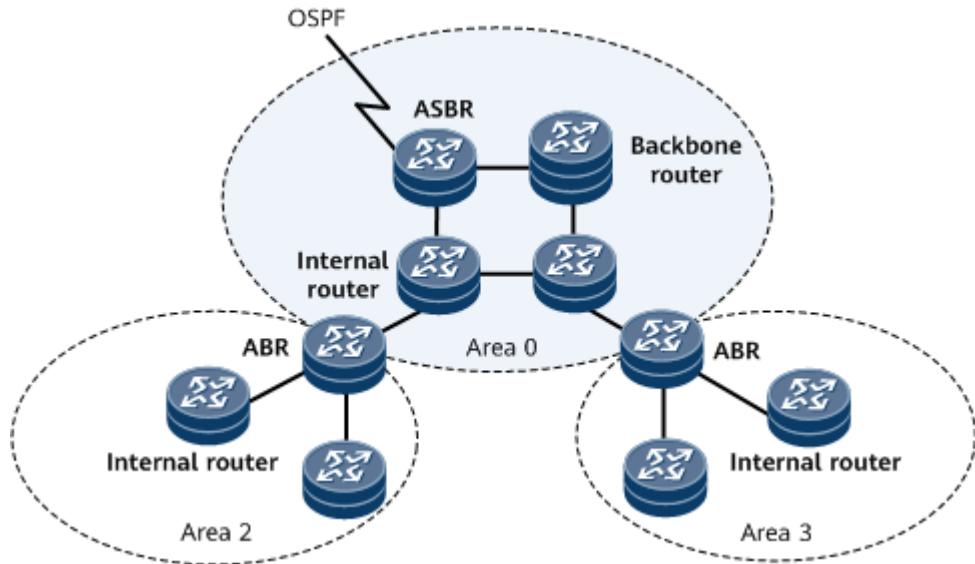

Table 1-17 Router types

Router Type	Description
Internal router	All interfaces of an internal router belong to the same OSPF area.
ABR	An ABR can belong to two or more areas, one of which must be a backbone area. An ABR connects the backbone area and non-backbone areas, and it can connect to the backbone area either physically or logically.
Backbone router	At least one interface on this type of router belongs to the backbone area. Internal routers in the backbone area and all ABRs are backbone routers.
ASBR	Exchanges routing information with other ASs. An ASBR may be an internal router or an ABR, and therefore may not necessarily reside at the border of an AS.

LSA

OSPF encapsulates routing information into LSAs for transmission. [Table 1-18](#) describes LSAs and their functions.

Table 1-18 Different types of LSAs and their functions

LSA Type	LSA Function
Router-LSA (Type 1)	Describes the link status and cost of a router. Router-LSAs are generated by each router and advertised within the area to which the router belongs.
Network-LSA (Type 2)	Describes the link status on the local network segment. Network-LSAs are generated by a designated router (DR) and advertised within the area to which the DR belongs.
Network-Summary-LSA (Type 3)	Describes routes on a network segment of an area. Network-Summary-LSAs are generated by an ABR and advertised to other areas, excluding totally stub areas and totally NSSAs. For example, an ABR belongs to both area 0 and area 1, area 0 has a network segment 10.1.1.0, and area 1 has a network segment 10.2.1.0. In this case, the ABR generates Type 3 LSAs destined for the network segment 10.2.1.0 for area 0, and Type 3 LSAs destined for the network segment 10.1.1.0 for area 1.
ASBR-Summary-LSA (Type 4)	Describes routes of an area to the ASBRs of other areas. ASBR-Summary-LSAs are generated by an ABR and advertised to other areas, excluding stub areas, totally stub area, NSSAs, and totally NSSAs.
AS-external-LSA (Type 5)	Describes AS external routes. AS-external-LSAs are generated by an ASBR and are advertised to all areas, excluding stub areas, totally stub areas, NSSAs, and totally NSSAs.
NSSA LSA (Type 7)	Describes AS external routes. NSSA-LSAs are generated by an ASBR and advertised only within NSSAs.
Opaque-LSA (Type 9/Type 10/Type 11)	<p>Opaque-LSAs provide a general mechanism for OSPF extension.</p> <ul style="list-style-type: none"> • Type 9 LSAs are advertised only on the network segment where the interface advertising the LSAs resides. The Grace LSAs used in graceful restart (GR) are one type of Type 9 LSA. • Type 10 LSAs are advertised within an OSPF area. The LSAs that are used to support traffic engineering (TE) are one type of Type 10 LSA. • Type 11 LSAs are advertised in an AS. The LSAs used to support routing loop detection for routes imported to OSPF are one type of Type 11 LSA.

Table 1-19 describes whether a type of LSA is supported in an area.

Table 1-19 Support status of LSAs in different types of areas

Area Type	Router-LSA (Type 1)	Network-LSA (Type 2)	Network-Summary-LSA (Type 3)	ASBR-Summary-LSA (Type 4)	AS-external-LSA (Type 5)	NSSA-LSA (Type 7)
Common area (including standard and backbone areas)	Supported	Supported	Supported	Supported	Supported	Not supported
Stub area	Supported	Supported	Supported	Not supported	Not supported	Not supported
Totally stub area	Supported	Supported	Not supported (except the default Type 3 LSA)	Not supported	Not supported	Not supported
NSSA	Supported	Supported	Supported	Not supported	Not supported	Supported
Totally NSSA	Supported	Supported	Not supported (except the default Type 3 LSA)	Not supported	Not supported	Supported

Packet Types

OSPF uses IP packets to encapsulate protocol packets. The protocol number is 89. OSPF packets are classified as Hello, database description (DD), link state request (LSR), link state update (LSU), or link state acknowledgment (LSAck) packets, as described in [Table 1-20](#).

Table 1-20 OSPF packets and their functions

Packet Type	Function
Hello packet	Hello packets are sent periodically to discover and maintain OSPF neighbor relationships.
Database description (DD) packet	A DD packet contains the summaries of LSAs in the local LSDB. DD packets are used for LSDB synchronization between two routers.
Link state request (LSR) packet	LSR packets are sent to OSPF neighbors to request required LSAs. A router sends LSR packets to its OSPF neighbor only after DD packets have been successfully exchanged.
Link state update (LSU) packet	LSU packets are used to transmit required LSAs to OSPF neighbors.
Link state acknowledgment (LSAck) packet	LSAck packets are used to acknowledge received LSAs.

Route Types

AS intra-area and inter-area routes describe the network structure within an AS, and AS external routes describe how to select routes to destinations outside the AS. OSPF classifies the imported AS external routes into Type 1 and Type 2.

Table 1-21 describes OSPF routes in descending order of priority.

Table 1-21 Route types

Route Type	Description
Intra Area	Intra-area route
Inter Area	Inter-area routes
Type 1 external route	This type of route is more reliable. Cost of a Type 1 external route = Cost of the route from a router to an ASBR + Cost of the route from the ASBR to the destination When multiple ASBRs exist, the cost of each Type 1 external route equals the cost of the route from the local device to an ASBR plus the cost of the route from the ASBR to the destination. The cost is used for route selection.

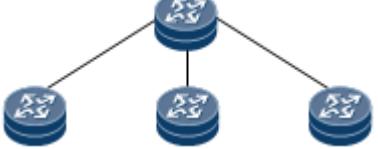

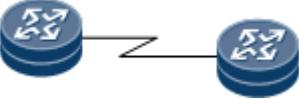

Route Type	Description
Type 2 external route	<p>Because a Type 2 external route offers low reliability, its cost is considered to be much greater than the cost of any internal route to an ASBR.</p> <p>Cost of a Type 2 external route = Cost of the route from an ASBR to the destination</p> <p>If multiple ASBRs have routes to the same destination, the route with the lowest cost from the corresponding ASBR to the destination is selected and imported. If the costs of the imported routes are the same, the router compares the costs of the routes from the local router to the corresponding ASBR and selects the route with the smallest cost to import. The cost of each Type 2 external route equals the cost of the route from the corresponding ASBR to the destination.</p>

OSPF Network Classification

According to the link layer protocol type, OSPF classifies networks into four types, as described in [Table 1-22](#).

Table 1-22 OSPF network classification

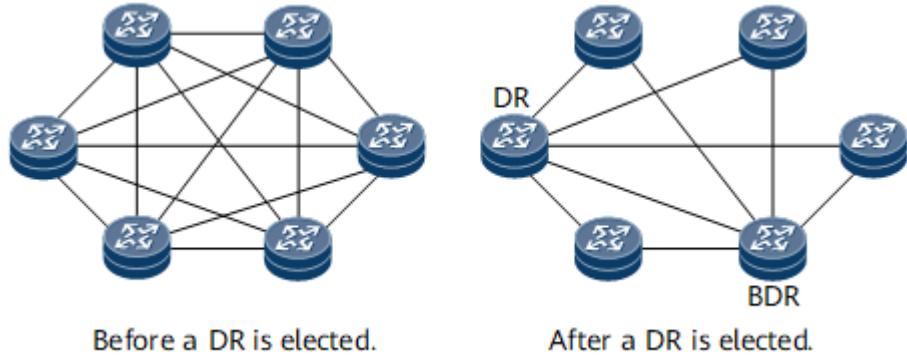

Network Type	Link Layer Protocol	Graph
Broadcast	<ul style="list-style-type: none"> • Ethernet • FDDI 	
NBMA	X.25	

Network Type	Link Layer Protocol	Graph
Point-to-Multipoint (P2MP)	No link layer protocol is considered as the P2MP type by default. P2MP is forcibly changed from another type of network. In most cases, a non-fully meshed NBMA network is changed to a P2MP network.	
P2P	<ul style="list-style-type: none"> • PPP • LAPB 	

DR and BDR

On broadcast or NBMA networks, any two routers need to exchange routing information. As shown in [Figure 1-60](#), n routers are deployed on the network. $n \times (n - 1)/2$ adjacencies must be established. Any route change on a router is transmitted to other routers, which wastes bandwidth resources. OSPF resolves this problem by defining a DR and a BDR. After a DR is elected, all routers send routing information only to the DR. Then the DR broadcasts LSAs. routers other than the DR and BDR are called DR others. The DR others establish only adjacencies with the DR and BDR and not with each other. This process reduces the number of adjacencies established between routers on broadcast or NBMA networks.

Figure 1-60 Network topologies before and after a DR election

If the original DR fails, routers must reelect a DR and the routers except the new DR must synchronize routing information to the new DR. This process is lengthy, which may cause incorrect route calculations. A BDR is used to shorten the process. The BDR is a backup for a DR. A BDR is elected together with a DR. The BDR establishes adjacencies with all routers on the network segment and exchanges routing information with them. If the DR fails, the BDR immediately becomes a new DR. Because no re-election is required and adjacencies have been

established, this process is very short. In this case, a new BDR needs to be elected. Although this process takes a long time, it does not affect route calculation.

The DR and BDR are not designated manually. Instead, they are elected by all routers on the network segment. The DR priority of an interface on the router determines whether the interface is qualified for DR or BDR election. On the local network segment, the routers whose DR priorities are greater than 0 are all candidates. Hello packets are used for the election. Each router adds information about the DR elected by itself to a Hello packet and sends the packet to other routers on the network segment. If two routers on the same network segment declare that they are DRs, the one with a higher DR priority wins. If they have the same priority, the one with a larger router ID wins. If the priority of a router is 0, it cannot be elected as a DR or BDR.

OSPF Multi-Process

OSPF multi-process allows multiple OSPF processes to independently run on the same router. Route exchange between different OSPF processes is similar to that between different routing protocols. A router's interface can belong only to one OSPF process.

A typical application of OSPF multi-process is that OSPF runs between PEs and CEs in VPN scenarios and OSPF is also used as an IGP on the VPN backbone network. The OSPF processes on the PEs are independent of each other.

OSPF Default Route

A default route is the route whose destination address and mask are both all 0s. If no matching route is found, the default route can be used by the router to forward packets.

OSPF default routes are generally applied to the following scenarios:

- An ABR in an area advertises Type 3 default summary LSAs within the area to help the routers in the area forward inter-area packets.
- An ASBR in an AS advertises Type 5 external default ASE LSAs or Type 7 external default NSSA LSAs to help the routers in the AS forward AS external packets.

OSPF routes are hierarchically managed. The priority of the default route carried in Type 3 LSAs is higher than the priority of the default route carried in Type 5 or Type 7 LSAs.

The rules for advertising OSPF default routes are as follows:

- An OSPF device can advertise default route LSAs only when it has an external interface.
- If an OSPF device has advertised default route LSAs, it no longer learns the same type of default route advertised by other routers. That is, the device no longer calculates the same type of default route LSA advertised by other routers. However, the corresponding LSAs exist in the database.
- If the advertisement of external default routes depends on other routes, the dependent routes cannot be the routes (learned by the local OSPF process) in the local OSPF routing domain. This is because external default routes are used to guide packet forwarding outside the domain. However, the next hops

of routes in the OSPF routing domain are within the domain, unable to guide packet forwarding outside the domain.

- Before a router advertises a default route, it checks whether a neighbor in the full state is present in area 0. The router advertises a default route only when a neighbor in the full state is present in area 0. If no such a neighbor exists, the backbone area cannot forward packets and advertising a default route is meaningless. For the concept of the Full State, see [OSPF Neighbor States](#).

Table 1-23 describes the principles for advertising default routes in different areas.

Table 1-23 Principles for advertising default routes in different areas

Area Type	Principles for Advertising Default Routes
Common area	<p>By default, OSPF devices in a common area do not generate default routes, even if they have default routes.</p> <p>When a default route is generated by another routing process, the router must advertise the default route to the entire OSPF AS. To achieve this, a command must be run on the ASBR to generate a default route. After the configuration is complete, the router generates a default ASE LSA (Type 5 LSA) and advertises it to the entire OSPF AS.</p> <p>If no default route exists on the ASBR, the router does not advertise a default route.</p>
Stub Area	<p>Type 5 LSAs cannot be advertised within a stub area.</p> <p>A router in the stub area must learn AS external routes from an ABR. The ABR automatically generates a default Summary LSA (Type 3 LSA) and advertises it within the entire stub area. Then the device can learn AS external routes from the ABR.</p>
Totally Stub Area	<p>Neither Type 3 (except default Type 3 LSAs) nor Type 5 LSAs can be advertised within a totally stub area.</p> <p>A router in the totally stub area must learn AS external and inter-area routes from an ABR. After you configure a totally stub area, an ABR automatically generates a default Summary LSA (Type 3 LSA) and advertises it within the entire totally stub area. Then the device can learn AS external and inter-area routes from the ABR.</p>

Area Type	Principles for Advertising Default Routes
NSSA	<p>A small number of AS external routes learned from the ASBR in an NSSA can be imported to the NSSA. External routes ASE LSAs (Type 5 LSAs) to other areas cannot be advertised within the NSSA. When at least a neighbor in Full status and an interface that is Up exist in the backbone area, the ABR automatically generates a Type 7 LSA carrying a default route and advertises it within the entire NSSA. In this case, a small number of routes are learned through the ASBR in the NSSA, and other routes are learned through the ABR in the NSSA. You can manually configure the ASBR to generate a default NSSA LSA (Type 7 LSA) and advertise it in the entire NSSA. In this manner, external routes can also be learned through the ASBR in the NSSA.</p> <p>An ABR does not translate Type 7 LSA default routes into Type 5 LSA default routes for transmission in the entire OSPF domain.</p>
Totally NSSA	<p>A totally NSSA does not allow ASE LSAs (Type 5 LSAs) of external routes or inter-area routes (Type 3 LSAs, except the default Type 3 LSAs) to be transmitted within the area.</p> <p>A router in this area must learn AS external routes from an ABR. After a totally NSSA is configured, the ABR automatically generates default Type 3 LSAs and Type 7 LSAs and advertises them within the entire totally NSSA. Then, AS external and inter-area routes can be advertised within the area through the ABR.</p>

OSPF Fundamentals

OSPF route calculation involves the following processes:

1. **Adjacency establishment**

The adjacency establishment process is as follows:

- a. The local and remote devices use OSPF interfaces to exchange Hello packets to establish a Neighbor relationship.
- b. The local and remote devices negotiate a master/slave relationship and exchange Database Description (DD) packets.
- c. The local and remote devices exchange link state advertisements (LSAs) to synchronize their link state databases (LSDBs).

2. **Route calculation:** OSPF uses the shortest path first (SPF) algorithm to calculate routes, implementing fast route convergence.

OSPF Neighbor States

To exchange routing information on an OSPF network, devices must establish adjacencies. The differences between neighbor relationships and adjacencies are described as follows:

- Neighbor relationship: After the local router starts, it uses an OSPF interface to send a Hello packet to the remote router. After the remote router receives

the packet, it checks whether the parameters carried in the packet are consistent with its own parameters. If the parameters carried in the packet are consistent with its own parameters, the remote router establishes a neighbor relationship with the local router.

- Adjacency: After two devices establish a neighbor relationship, they exchange DD packets and LSAs to establish an adjacency.

OSPF has eight neighbor states: Down, Attempt, Init, 2-way, Exstart, Exchange, Loading, and Full. Down, 2-way, and Full are stable states. Attempt, Init, Exstart, Exchange, and Loading are unstable states, which last only several minutes. [Figure 1-61](#) shows the eight neighbor states.

Figure 1-61 OSPF neighbor states

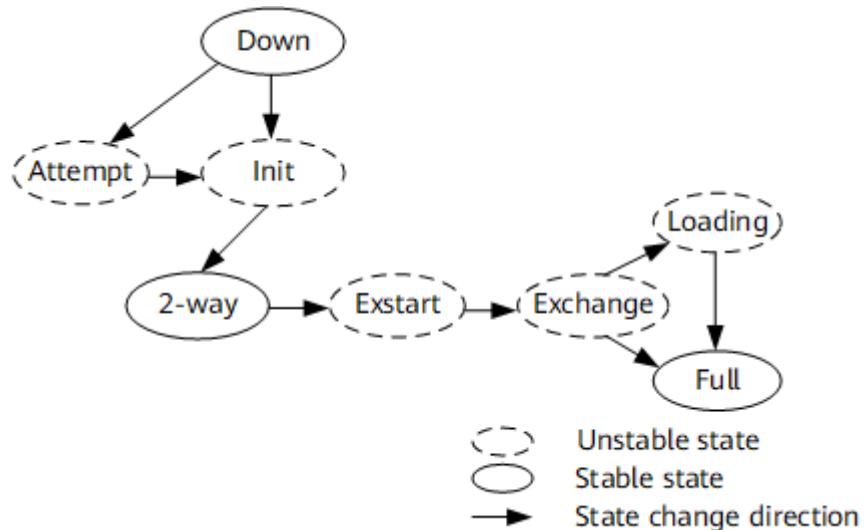

Table 1-24 OSPF neighbor states and their meanings

OSPF Neighbor State	Description
Down	This is the initial state of a neighbor conversation. This state indicates that no Hello packet is received from the neighbor within the dead interval.
Attempt	In this state, the device periodically sends Hello packets to manually configured neighbors. NOTE This state applies only to non-broadcast multiple access (NBMA) interfaces.
Init	This state indicates that the local end has received Hello packets from its neighbor, but the neighbor does not receive Hello packets from the local end.

OSPF Neighbor State	Description
2-way	This state indicates that a device has received Hello packets from its neighbors and Neighbor relationship have been established between the devices. If no adjacency needs to be established, the neighbors remain in the 2-way state. If adjacencies need to be established, the neighbors enter the Exstart state.
Exstart	In the Exstart state, devices establish a master/slave relationship to ensure that DD packets are sequentially exchanged.
Exchange	In the Exchange state, routers exchange DD packets. A router uses a DD packet to describe its own LSDB and sends the packet to its neighbors.
Loading	In the Loading state, a device sends Link State Request (LSR) packets to its neighbors to request their LSAs for LSDB synchronization.
Full	In this state, a device establishes adjacencies with its OSPF neighbors and all LSDBs have been synchronized.

NOTE

The neighbor state of the local device may be different from that of a remote device. For example, the neighbor state of the local router is Full, but the neighbor state of the remote router is Loading.

Adjacency Establishment

Adjacencies can be established in either of the following situations:

- Two routers have established a neighbor relationship and communicate for the first time.
- The designated router (DR) or backup designated router (BDR) on a network segment changes.

The OSPF adjacency establishment process varies according to the network type (broadcast, NBMA, P2P, or P2MP).

OSPF adjacency establishment on a broadcast network

[Figure 1-62](#) shows the adjacency establishment process on a broadcast network.

On the broadcast network, the DR and BDR establish adjacencies with each router on the same network segment, but DR others establish only neighbor relationships.

Figure 1-62 OSPF adjacency establishment process on a broadcast network

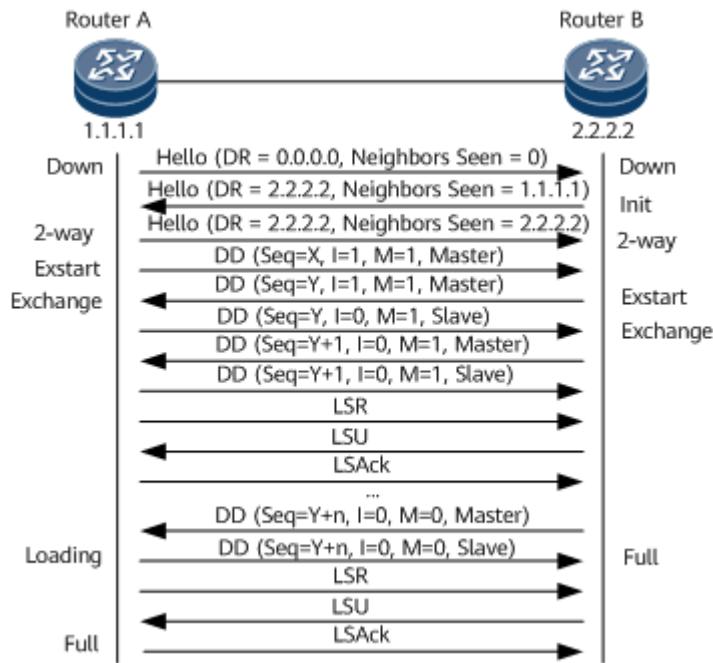

Figure 1-62 shows the OSPF adjacency establishment process on a broadcast network.

1. Neighbor relationship establishment

- Router A uses the multicast address 224.0.0.5 to send a Hello packet through the OSPF interface connected to a broadcast network. In this case, Router A does not know which router is the DR or which router is a neighbor. Therefore, the DR field is 0.0.0.0, and the Neighbors Seen field is 0.
- After Router B receives the packet, it returns a Hello packet to Router A. The returned packet carries the DR field of 2.2.2.2 (ID of Router B) and the Neighbors Seen field of 1.1.1.1 (Router A's router ID). Router A has been discovered but its router ID is less than that of Router B, and therefore Router B regards itself as a DR. Then Router B's state changes to Init.
- After Router A receives the packet, Router A's state changes to 2-way.

NOTE

The following procedures are not performed for DR others on a broadcast network.

2. Master/Slave negotiation and DD packet exchange

- Router A sends a DD packet. The packet carries the following fields:
 - Seq field: The value x indicates the sequence number is x .
 - I field: The value 1 indicates that the packet is the first DD packet, which is used to negotiate a master/slave relationship and does not carry LSA summaries.
 - M field: The value 1 indicates that the packet is not the last DD packet.

- MS field: The value 1 indicates that Router A declares itself a master.

To improve transmission efficiency, Router A and Router B determine which LSAs in each other's LSDB need to be updated. If one party determines that an LSA of the other party is already in its own LSDB, it does not send an LSR packet for updating the LSA to the other party. To achieve the preceding purpose, Router A and Router B first send DD packets, which carry summaries of LSAs in their own LSDBs. Each summary identifies an LSA. To ensure packet transmission reliability, a master/slave relationship must be determined during DD packet exchange. One party serving as a master uses the Seq field to define a sequence number. The master increases the sequence number by one each time it sends a DD packet. When the other party serving as a slave sends a DD packet, it adds the sequence number carried in the last DD packet received from the master to the Seq field of the packet.

- b. After receiving the DD packet from Router A, Router B sets the neighbor state of Router A to Exstart and returns a DD packet. The returned packet does not carry LSA summaries either. Because Router B's router ID is greater than Router A's router ID, Router B declares itself a master and sets the Seq field to y .
- c. After Router A receives the DD packet, it agrees that Router B is a master and Router A's state changes to Exchange. Then Router A sends a DD packet to Router B to transmit LSA summaries. The packet carries the Seq field of y and the MS field of 0. The value 0 indicates that Router A declares itself a slave.
- d. After Router B receives the packet, Router B's state changes to Exchange and Router B sends a new DD packet containing its own LSA summaries to Router A. The value of the Seq field carried in the new DD packet is changed to $y+1$.

Router A uses the same sequence number as Router B to confirm that it has received DD packets from Router B. Router B uses the sequence number plus one to confirm that it has received DD packets from Router A. When Router B sends the last DD packet, it sets the M field of the packet to 0.

3. LSDB synchronization (through LSA requests, transmission, and response)

- a. After Router A receives the last DD packet, it finds that many LSAs in Router B's LSDB do not exist in its own LSDB, so Router A's state changes to Loading. After Router B receives the last DD packet from Router A, Router B's state directly changes to Full, because Router B's LSDB already contains all LSAs of Router A.
- b. Router A sends an LSR packet for updating LSAs to Router B. Router B returns an LSU packet to Router A. After Router A receives the packet, it sends an LSAck packet for acknowledgment.

The preceding procedures continue until the LSAs in Router A's LSDB are the same as those in Router B's LSDB. Router A sets the state of the neighbor relationship with Router B to Full. After the routers exchange DD packets and update all LSAs, the adjacency is established.

OSPF adjacency establishment on an NBMA network

The adjacency establishment process on an NBMA network is different from that on a broadcast network only before DD packets are exchanged, as marked in blue in [Figure 1-63](#).

On an NBMA network, all routers establish adjacencies only with the DR and BDR.

Figure 1-63 OSPF adjacency establishment process on an NBMA network

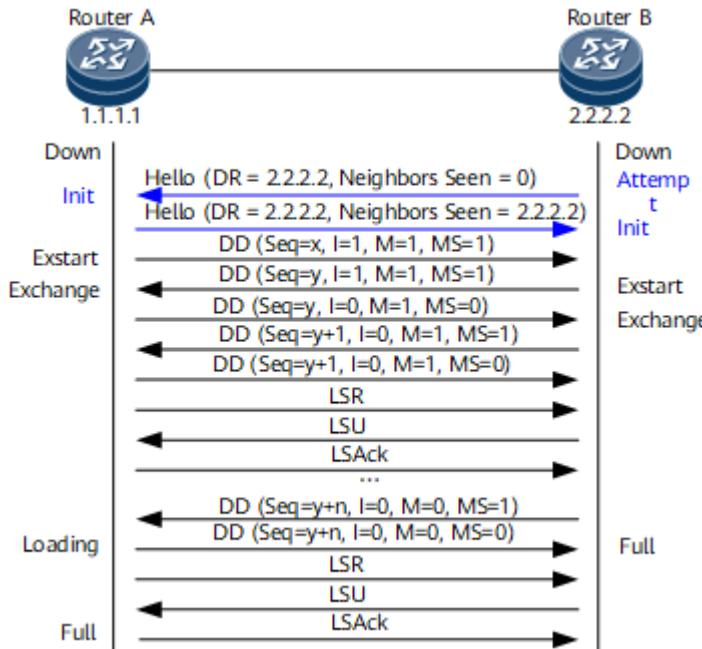

Figure 1-63 shows the process of OSPF adjacency establishment on an NBMA network.

1. Neighbor relationship establishment

- After Router B sends a Hello packet to a down interface of Router A, Router B's state changes to Attempt. At this time, Router B regards itself as a DR but does not know which router is the neighbor. The packet carries the DR field of 2.2.2.2 (ID of Router B) and the Neighbors Seen field of 0.
- After Router A receives the Hello packet, Router A sets the neighbor state to Init and returns a Hello packet. Router A agrees that Router B is a DR. The DR and Neighbors Seen fields are both set to 2.2.2.2.

NOTE

The following procedures are not performed for DR others (routers) on an NBMA network.

2. Master/Slave relationship negotiation and DD packet exchange

The procedures for negotiating a master/slave relationship and exchanging DD packets on an NBMA network are the same as those on a broadcast network.

3. The procedure for synchronizing LSDBs (through LSA requests, transmission, and response) on this type of network is the same as that on a broadcast network.

OSPF adjacency establishment on a point-to-point (P2P)/Point-to-multipoint (P2MP) network

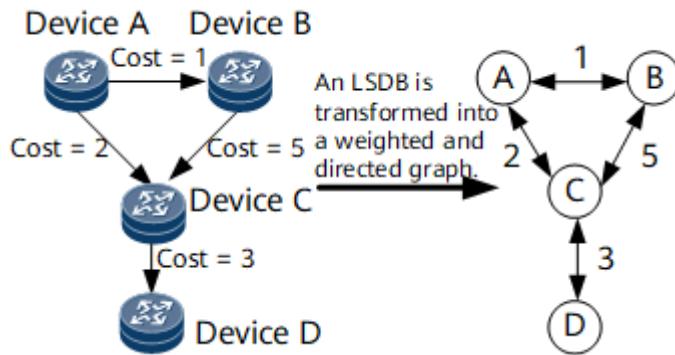

Adjacency establishment on a P2P or P2MP network is the same as that on a broadcast network except that no DR or BDR needs to be elected on the P2P or P2MP network. On a P2P network, DD packets are sent in multicast mode. On a P2MP network, DD packets are sent in unicast mode.

Route Calculation

OSPF uses the shortest path first (SPF) algorithm to calculate routes, implementing fast route convergence.

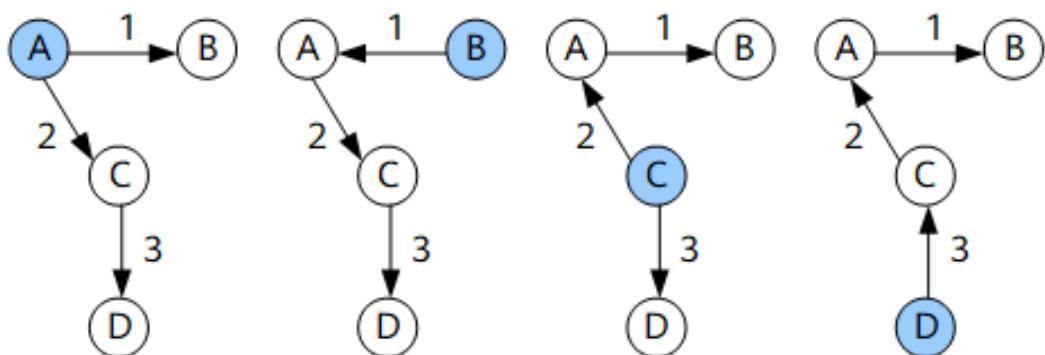

OSPF uses an LSA to describe the network topology. A Router LSA describes the attributes of a link between routers. A router transforms its LSDB into a weighted, directed graph, which reflects the topology of the entire network. All routers have the same graph. [Figure 1-64](#) shows a weighted, directed graph.

[Figure 1-64](#) Weighted, directed graph generated based on the LSDB

Based on the graph, each router uses the SPF algorithm to calculate an SPT with itself as the root. The SPT shows routes to nodes in the AS, as shown in [Figure 1-65](#).

[Figure 1-65](#) SPTs

When a router's LSDB changes, the router recalculates a shortest path. Frequent SPF calculations consume a large number of resources and affect router efficiency. Changing the interval between SPF calculations can prevent resource consumption caused by frequent LSDB changes. The default interval between SPF calculations is 5 seconds.

The route calculation process is as follows:

1. A device calculates intra-area routes.

The router uses an SPF algorithm to calculate shortest paths to other routers. Router LSAs and Network LSAs accurately describe the network topology in an area. Based on the network topology described by a Router LSA, the router calculates paths to each network segment.

 **NOTE**

If multiple equal-cost routes are produced during route calculation, the SPF algorithm retains all these routes in the LSDB.

2. The device calculates inter-area routes.

For the devices in an area, the network segment of the routes in an adjacent area is directly connected to the area border router (ABR). Because the shortest path to the ABR has been calculated in the preceding step, the devices can directly check a Network Summary LSA to obtain the shortest path to the network segment. The autonomous system boundary router (ASBR) can also be considered connected to the ABR. Therefore, the shortest path to the ASBR can also be calculated in this phase.

 **NOTE**

If the router performing an SPF calculation is an ABR, it needs to check only Network Summary LSAs in the backbone area.

If there are multiple paths to an ASBR, check whether the rules for selecting a path to the ASBR among intra-area and inter-area paths on different types of devices are the same. If the rules are different, routing loops may occur.

The RFC 1583 compatibility mode and RFC 1583 non-compatibility mode may affect path selection rules. Even in the same mode, the path selection rules on devices from different vendors may be slightly different. In this case, the rules used in RFC 1583 compatibility mode or RFC 1583 non-compatibility mode for selecting a path to an ASBR can be adjusted, preventing loops to some extent.

3. The router calculates AS external routes.

AS external routes can be considered to be directly connected to the ASBR. Because the shortest path to the ASBR has been calculated in the preceding phase, the device can check AS External LSAs to obtain the shortest paths to other ASs.

OSPF Route Control

You can use the following features to control the advertising and receiving of OSPF routes. These features meet requirements for network planning and traffic management.

- **Route summarization**

Route summarization enables a device to summarize routes with the same prefix into a single summary route and to advertise only the summary route to other areas. Route summarization reduces the size of a routing table and improves device performance.

- **Route filtering**

OSPF can use routing policies to filter routes. By default, OSPF does not filter routes.

- **OSPF Database Overflow**

Setting the maximum number of external routes in the LSDB dynamically limits the size of the OSPF LSDB and prevents the problem caused by the overflow of the OSPF LSDB.

Route Summarization

When a large OSPF network is deployed, an OSPF routing table includes a large number of routing entries. To accelerate route lookup and simplify management, configure route summarization to reduce the size of the OSPF routing table. If a link frequently alternates between Up and Down, the links not involved in the route summarization are not affected. This process prevents route flapping and improves network stability.

OSPF supports two route summarization modes.

- ABR summarization

When an ABR transmits routing information to other areas, it generates Type 3 LSAs for each network segment. If consecutive network segments exist in this area, you can summarize these network segments into a single network segment. The ABR generates one LSA for the summarized network segment and advertises only that LSA.

- ASBR summarization

If route summarization has been configured and the local router is an ASBR, the local router summarizes imported Type 5 LSAs within the summarized address range. If an NSSA is configured, imported Type 7 LSAs within the summarized address range also need to be summarized.

If the local router is both an ASBR and an ABR, it summarizes Type 5 LSAs translated from Type 7 LSAs.

Route Filtering

OSPF routing policies include access control lists (ACLs), IP prefix lists, and route-policies. For details about these policies, see the section "Routing Policy" in the *NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X Feature Description - IP Routing*.

OSPF route filtering applies in the following aspects:

- Route import

OSPF can import the routes learned by other routing protocols. You can configure a routing policy to filter routes and import only the routes that meet the filtering conditions. Only an ASBR can import routes, and therefore a routing policy for importing routes must be configured on the ASBR.

- Advertising of imported routes

OSPF advertises imported routes to its neighbors. Only an ASBR can import routes, and therefore a routing policy for the advertising of imported routes must be configured on the ASBR.

If OSPF imports a large number of external routes and advertises them to a device with a smaller routing table capacity, the device may restart unexpectedly. To prevent this problem, configure a limit on the number of imported external routes to be advertised by OSPF to ensure stable device running.

- Route learning

By configuring filtering rules, you can configure OSPF to filter received intra-area, inter-area, and AS external routes. Such filtering only determines whether to add routing entries. That is, all routes in the OSPF routing table can be calculated and advertised normally, but only the routes that match the filtering rules can be added to the local routing table.

During route learning, LSAs are not filtered. Instead, only the routes calculated based on LSAs are filtered to determine whether they are added to the routing table. Therefore, the learned LSAs are complete.

- Inter-area LSA learning

An ABR in an area can be configured to filter Summary LSAs advertised to the area. The ABR can advertise only Summary LSAs, and therefore inter-area LSA learning is valid only on the ABR.

During inter-area LSA learning, the LSAs advertised to the area are directly filtered.

- Inter-area LSA advertising

An ABR in an area can be configured to filter Summary LSAs advertised out of the local area. The ABR can advertise only Summary LSAs, and therefore inter-area LSA advertisement is valid only on the ABR.

OSPF Database Overflow

OSPF requires that devices in the same area have the same LSDB. As the number of routes increase continually, some devices cannot carry excess routing information due to limited system resources. This situation is called an OSPF database overflow.

You can configure stub areas or NSSAs to prevent resource exhaustion caused by continually increasing routing information. However, configuring stub areas or NSSAs cannot prevent an OSPF database overflow caused by a sharp increase in dynamic routes. To resolve this issue, set the maximum number of external routes supported by the LSDB to dynamically limit the LSDB's size.

 NOTE

The maximum number of external routes configured for all devices in the OSPF AS must be the same.

When the number of external routes in the LSDB reaches the maximum number, the device enters the overload state and starts the overflow timer at the same time. The device automatically exits from the overflow state after the overflow timer expires. **Table 1-25** describes the operations performed by the device after it enters or exits from the overload state.

Table 1-25 Description of the OSPF database overflow state

Phase	OSPF Processing Procedure
Staying at overload state	<p>Deletes self-generated non-default external routes and stops advertising non-default external routes.</p> <p>Discards newly received non-default external routes and does not reply with a Link State Acknowledgment (LSAck) packet.</p> <p>Checks whether the number of external routes is still greater than the configured maximum number when the overflow timer expires.</p> <ul style="list-style-type: none"> • Restarts the timer if the number of external routes is greater than or equal to the configured maximum number. • Exits from the overflow state if the number of external routes is less than the configured maximum number.
Exiting from the overflow state	<p>Ends the overflow timer.</p> <p>Advertises non-default external routes.</p> <p>Accepts newly received non-default external routes and replies with LSack packets.</p>

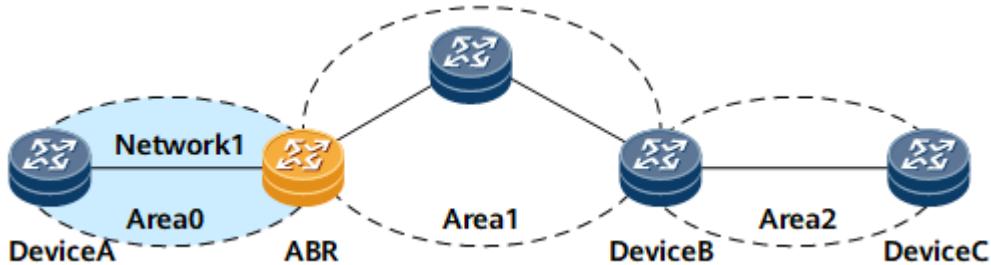

OSPF Virtual Link

Background

All non-backbone areas must be connected to the backbone area during OSPF deployment to ensure that all areas are reachable.

In [Figure 1-66](#), area 2 is not connected to area 0 (backbone area), and Device B is not an ABR. Therefore, Device B does not generate routing information about network 1 in area 0, and Device C does not have a route to network 1.

Figure 1-66 Non-backbone area not connected to the backbone area

Some non-backbone areas may not be connected to the backbone area. You can configure an OSPF virtual link to resolve this issue.

Related Concepts

A virtual link refers to a logical channel established between two ABRs over a non-backbone area.

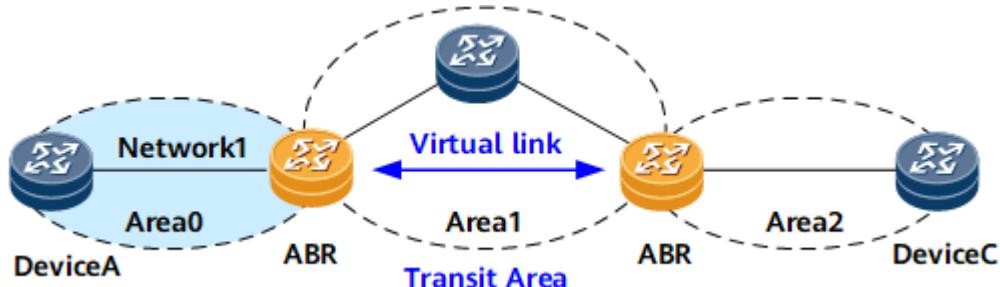

- A virtual link must be configured at both ends of the link.
- The non-backbone area involved is called a transit area.

A virtual link is similar to a point-to-point (P2P) connection established between two ABRs. You can configure interface parameters, such as the interval at which Hello packets are sent, at both ends of the virtual link as you do on physical interfaces.

Principles

In [Figure 1-67](#), two ABRs use a virtual link to directly transmit OSPF packets. The device between the two ABRs only forwards packets. Because the destination of OSPF packets is not the device, the device transparently transmits the OSPF packets as common IP packets.

Figure 1-67 OSPF virtual link

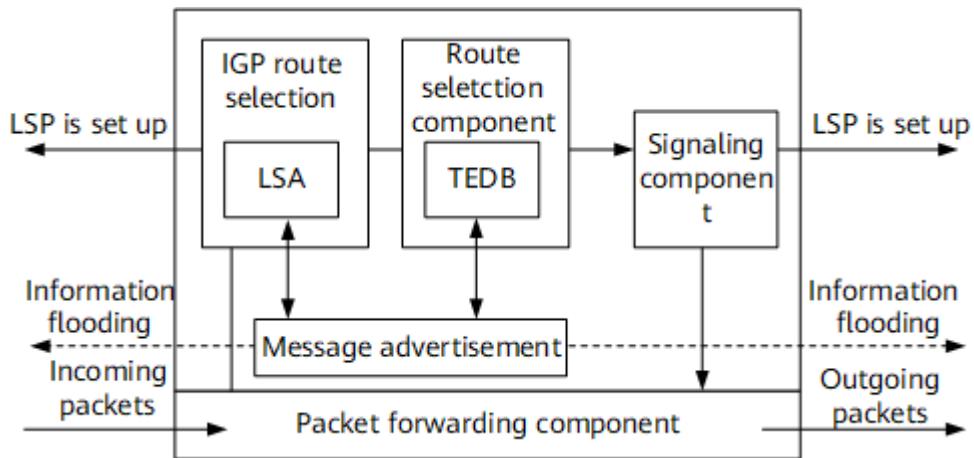

OSPF TE

OSPF Traffic Engineering (TE) is developed based on OSPF to support Multiprotocol Label Switching (MPLS) TE and establish and maintain TE LSPs. In the MPLS TE architecture described in "MPLS Feature Description", OSPF functions as the information advertising component, responsible for collecting and advertising MPLS TE information.

In addition to the network topology, TE needs to know network constraints, such as the bandwidth, TE metric, administrative group, and affinity attribute. However, current OSPF functions cannot meet these requirements. Therefore, OSPF introduces a new type of LSAs to advertise network constraints. Based on the network constraints, the Constraint Shortest Path First (CSPF) algorithm can calculate the path subject to specified constraints.

Figure 1-68 Overview of OSPF in the MPLS TE architecture

OSPF in the MPLS TE Architecture

In the MPLS TE architecture, OSPF functions as the information advertising component:

- Collects related information about TE.
- Floods TE information to devices in the same area.
- Uses the collected TE information to form the TE database (TEDB) so that CSPF can calculate routes.

OSPF does not care about information content or how MPLS uses the information.

TE-LSA

OSPF uses a new type of LSA (Type 10 opaque LSA) to collect and advertise TE information. Such LSAs contain the link status information required by TE, including the maximum link bandwidth, maximum reservable bandwidth, current reserved bandwidth, and link color. Based on the OSPF flooding mechanism, Type 10 opaque LSAs synchronize link status information among devices in an area to form a uniform TEDB for route calculation.

Interaction Between OSPF TE and CSPF

OSPF uses Type 10 LSAs to collect TE information in an area, such as the bandwidth, priority, and link metrics. After processing the collected TE information, OSPF provides it for CSPF to calculate routes.

IGP Shortcut and Forwarding Adjacency

OSPF supports IGP shortcut and forwarding adjacency. The two features allow OSPF to use a tunnel interface as an outbound interface to reach a destination.

Differences between IGP shortcut and forwarding adjacency are as follows:

- An IGP shortcut-enabled device uses a tunnel interface as an outbound interface but does not advertise the tunnel interface to neighbors. Therefore, other devices cannot use this tunnel.

- A forwarding adjacency-enabled device uses a tunnel interface as an outbound interface and advertises the tunnel interface to neighbors. Therefore, other devices can use this tunnel.
- IGP shortcut is unidirectional and needs to be configured only on the device that uses IGP shortcut.

OSPF SRLG

OSPF supports the applications of the Shared Risk Link Group (SRLG) in MPLS by obtaining information about the TE SRLG flooded among devices in an area. For details, refer to the chapter "MPLS" in this manual.

OSPF TE Tunnel Microloop Avoidance

If a network fault occurs, IGP convergence is triggered. In this case, a transient forwarding status inconsistency may occur among nodes because of their different convergence rates, which poses the risk of microloops. If the outbound interface of a route before IGP convergence is a shortcut TE tunnel interface and the OSPF TE tunnel microloop avoidance function is enabled, the outbound interface of the route remains unchanged during IGP convergence. In this case, traffic is forwarded through a hot standby TE tunnel, and the forwarding process does not depend on IGP convergence on each device, preventing microloops.

OSPF VPN

Definition

As an extension of OSPF, OSPF VPN enables Provider Edges (PEs) and Customer Edges (CEs) in VPNs to run OSPF for interworking and use OSPF to learn and advertise routes.

Purpose

As a widely used IGP, in most cases, OSPF runs in VPNs. If OSPF runs between PEs and CEs, and PEs use OSPF to advertise VPN routes to CEs, no other routing protocols need to be configured on CEs for interworking with PEs, which simplifies management and configuration of CEs.

Running OSPF Between PEs and CEs

In BGP/MPLS VPN, Multi-Protocol BGP (MP-BGP) is used to transmit routing information between PEs, whereas OSPF is used to learn and advertise routes between PEs and CEs.

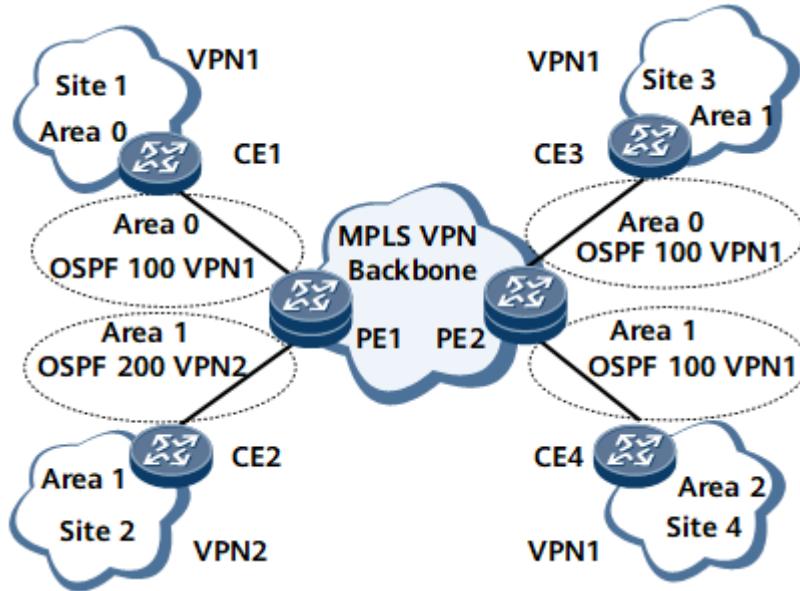

Running OSPF between PEs and CEs has the following benefits:

- OSPF is used in a site to learn routes. Running OSPF between PEs and CEs can reduce the number of the protocol types that CEs must support.
- Similarly, running OSPF both in a site and between PEs and CEs simplifies the work of network administrators and reduces the number of protocols that network administrators must be familiar with.

- When a network using OSPF but not VPN on the backbone network begins to use BGP/MPLS VPN, running OSPF between PEs and CEs facilitates the transition.

In [Figure 1-69](#), CE1, CE3, and CE4 belong to VPN 1, and the numbers following OSPF refer to the process IDs of the multiple OSPF instances running on PEs.

Figure 1-69 Networking with OSPF running between PEs and CEs

The routes that PE1 receives from CE1 are advertised to CE3 and CE4 as follows:

- PE1 imports OSPF routes of CE1 into BGP and converts them to BGP VPNv4 routes.
- PE1 uses MP-BGP to advertise the BGP VPNv4 routes to PE2.
- PE2 imports the BGP VPNv4 routes into OSPF and then advertises these routes to CE3 and CE4.

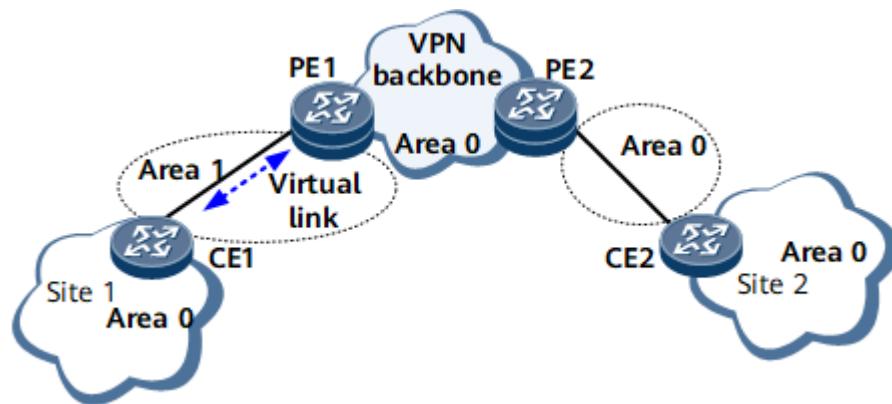

The process of advertising routes of CE4 or CE3 to CE1 is the same as the preceding process.

Configuring OSPF Areas Between PEs and CEs

OSPF areas between PEs and CEs can be non-backbone or backbone areas (Area 0). PEs can function only as ABRs.

In the extended application of OSPF VPN, the MPLS VPN backbone network serves as Area 0. OSPF requires that Area 0 be contiguous. Therefore, Area 0 of all VPN sites must be connected to the MPLS VPN backbone network. If a VPN site has OSPF Area 0, the PEs that CEs access must be connected to the backbone area of this VPN site through Area 0. If no physical link is available to directly connect PEs to the backbone area, a virtual link can be deployed between the PEs and the backbone area. [Figure 1-70](#) shows the networking for configuring OSPF areas between PEs and CEs.

Figure 1-70 Configuring OSPF areas between PEs and CEs

A non-backbone area (Area 1) is configured between PE1 and CE1, and a backbone area (Area 0) is configured in Site 1. The backbone area in Site 1 is separated from the VPN backbone area. To ensure that the backbone areas are contiguous, a virtual link is configured between PE1 and CE1.

OSPF Domain ID

If inter-area routes are advertised between local and remote OSPF areas, these areas are considered to be in the same OSPF domain.

- Domain IDs identify domains.
- Each OSPF domain has one or more domain IDs. If more than one domain ID is available, one of the domain IDs is a primary ID, and the others are secondary IDs.
- If an OSPF instance does not have a specific domain ID, its ID is considered as null.

Before advertising the remote routes sent by BGP to CEs, PEs need to determine the type of OSPF routes (Type 3, Type 5, or Type 7) to be advertised to CEs based on domain IDs.

- If local domain IDs are the same as or compatible with remote domain IDs in BGP routes, PEs advertise Type 3 routes.
- Otherwise, Type 5 or Type 7 routes are advertised.

Table 1-26 Domain ID

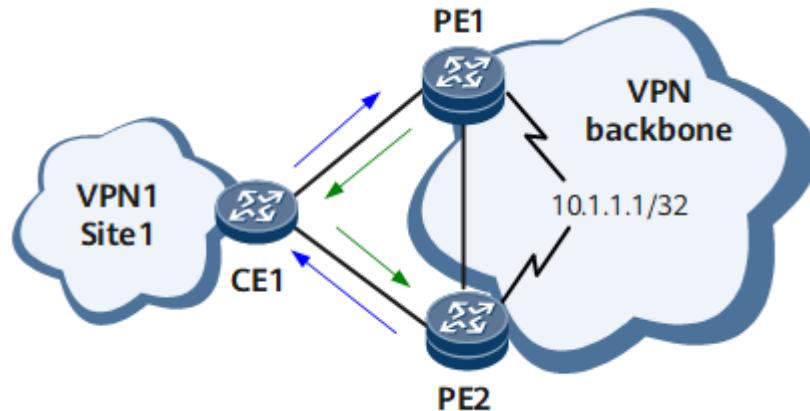

Relationship Between Local and Remote Domain IDs	Comparison Between Local and Remote Domain IDs	Type of the Generated Routes
Both the local and remote domain IDs are null.	Equal	Inter-area routes

Relationship Between Local and Remote Domain IDs	Comparison Between Local and Remote Domain IDs	Type of the Generated Routes
The remote domain ID is the same as the local primary domain ID or one of the local secondary domain IDs.	Equal	Inter-area routes
The remote domain ID is different from the local primary domain ID or any of the local secondary domain IDs.	Not equal	If the local area is a non-NSSA, external routes are generated. If the local area is an NSSA, NSSA routes are generated.

Routing Loop Prevention

Routing loops may occur between PEs and CEs when OSPF and BGP learn routes from each other.

Figure 1-71 Networking for OSPF VPN routing loops

In [Figure 1-71](#), on PE1, OSPF imports a BGP route destined for 10.1.1.1/32 and then generates and advertises a Type 5 or Type 7 LSA to CE1. Then, CE1 learns an OSPF route with 10.1.1.1/32 as the destination address and PE1 as the next hop and advertises the route to PE2. Therefore, PE2 learns an OSPF route with 10.1.1.1/32 as the destination address and CE1 as the next hop.

Similarly, CE1 also learns an OSPF route with 10.1.1.1/32 as the destination address and PE2 as the next hop. PE1 learns an OSPF route with 10.1.1.1/32 as the destination address and CE1 as the next hop.

As a result, CE1 has two equal-cost routes with PE1 and PE2 as next hops respectively, and the next hop of the routes from PE1 and PE2 to 10.1.1.1/32 is CE1, which leads to a routing loop.

In addition, the priority of an OSPF route is higher than that of a BGP route. Therefore, on PE1 and PE2, BGP routes to 10.1.1.1/32 are replaced with the OSPF route, and the OSPF route with 10.1.1.1/32 as the destination address and CE1 as the next hop is active in the routing tables of PE1 and PE2.

The BGP route is inactive, and therefore, the LSA generated when this route is imported by OSPF is deleted, which causes the OSPF route to be withdrawn. As a result, no OSPF route exists in the routing table, and the BGP route becomes active again. This cycle causes route flapping.

OSPF VPN provides a few solutions to routing loops, as described in [Table 1-27](#).

Table 1-27 Routing loop prevention measures

Feature	Definition	Function
DN-bit	It is a flag bit used by OSPF multi-instance processes to prevent routing loops.	After OSPF multi-instance is configured on the router (a PE or an MCE), the router sets the DN-bit of generated Type 3, Type 5, or Type 7 LSAs to 1 and retains the DN-bit (0) of other LSAs. When calculating routes, the OSPF multi-instance process on the router ignores the LSAs in which the DN bit is set. This prevents routing loops that occur when LSAs sent by a PE (or MCE) are sent back to the PE (or MCE) through a CE. On the network shown in Figure 1-71 , PE1 sets the DN bit in the generated Type 3, Type 5, or Type 7 LSAs to 1 and advertises these LSAs to CEs. Then, the CEs send the LSAs to PE2. Upon reception of these LSAs, PE2 checks the DN bit of the LSAs and finds that the DN bit is 1. Therefore, PE2 ignores the LSAs, which prevents routing loops.

Feature	Definition	Function
VPN Route Tag	<p>The VPN route tag is carried in Type 5 or Type 7 LSAs generated by PEs based on the received BGP VPN route.</p> <p>It is not carried in BGP extended community attributes. The VPN route tag is valid only on PEs that receive BGP routes and generate OSPF LSAs.</p>	When a PE detects that the VPN route tag in the incoming LSA is the same as the local route tag, the PE ignores the LSA, which prevents routing loops.
Default route	<p>It is a route whose destination IP address and mask are both 0.</p>	Default routes are used to forward traffic from CEs or sites where CEs reside to the VPN backbone network.

Disabling Routing Loop Prevention

NOTICE

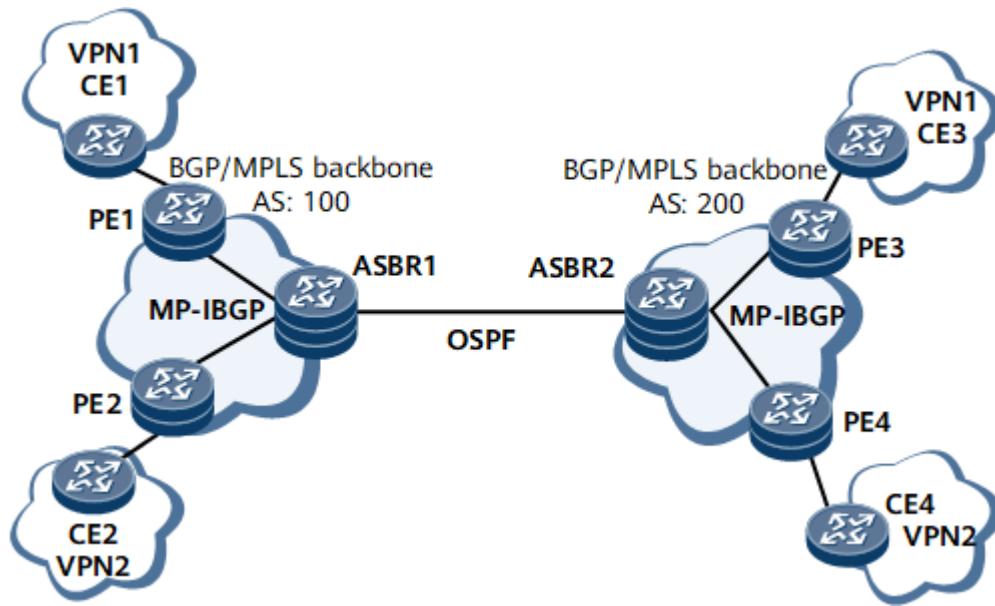

Exercise caution when disabling routing loop prevention because it may cause routing loops.

During BGP or OSPF route exchanges, routing loop prevention prevents OSPF routing loops in VPN sites.

In the inter-AS VPN Option A scenario, if OSPF runs between ASBRs to transmit VPN routes, the remote ASBR may fail to learn the OSPF routes sent by the local ASBR due to the routing loop prevention mechanism.

In [Figure 1-72](#), inter-AS VPN Option A is deployed with OSPF running between PE1 and CE1. In this example, CE1 sends VPN routes to CE3, and OSPF runs between PE1 and CE1.

Figure 1-72 Networking for inter-AS VPN Option A

1. PE1 learns routes to CE1 using the OSPF process in a VPN instance, imports these routes into MP-BGP, and sends the MP-BGP routes to ASBR1.
2. After receiving the MP-BGP routes, ASBR1 imports the routes into the OSPF process in a VPN instance and generates Type 3, Type 5, or Type 7 LSAs carrying DN bit 1.
3. ASBR2 uses OSPF to learn these LSAs and checks the DN bit of each LSA. After learning that the DN bit in each LSA is 1, ASBR2 does not add the routes carried in these LSAs to its routing table.

The routing loop prevention mechanism prevents ASBR2 from learning the OSPF routes sent from ASBR1. As a result, CE1 cannot communicate with CE3.

To address the preceding problem, use either of the following methods:

- Disable the device from setting the DN bit to 1 in the LSAs when importing BGP routes into OSPF. For example, if ASBR1 does not set the DN bit to 1 when importing MP-BGP routes into OSPF. After ASBR2 receives these routes and finds that the DN bit in the LSAs carrying these routes is 0, ASBR2 will add the routes to its routing table.
- Disable the device from checking the DN bit after receiving LSAs. For example, ASBR1 sets the DN bit to 1 in LSAs when importing MP-BGP routes into OSPF. ASBR2, however, does not check the DN bit after receiving these LSAs.

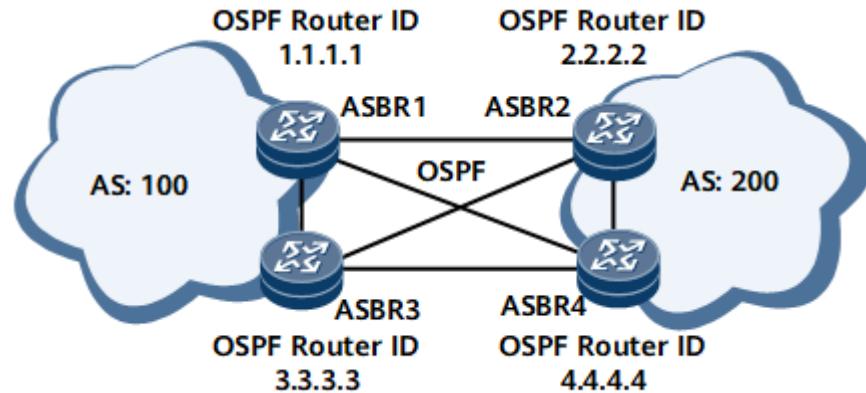

The preceding methods can be used based on specific types of LSAs. You can configure a sender to determine whether to set the DN bit to 1 or configure a receiver to determine whether to check the DN bit in the Type 3 LSAs based on the router ID of the device that generates the Type 3 LSAs.

In the inter-AS VPN Option A scenario shown in [Figure 1-73](#), the four ASBRs are fully meshed and run OSPF. ASBR2 may receive the Type 3, Type 5, or Type 7 LSAs generated on ASBR4. If ASBR2 is not configured to check the DN bit in the LSAs,

ASBR2 will accept the Type 3 LSAs, which may cause routing loops, as described in [Routing Loop Prevention](#). ASBR2 will deny the Type 5 or Type 7 LSAs, because the VPN route tags carried in the LSAs are the same as the default VPN route tag of the OSPF process on ASBR2.

To address the routing loop problem caused by Type 3 LSAs, ASBR2 can be disabled from checking the DN bit in the Type 3 LSAs generated by devices with router ID 1.1.1.1 and router ID 3.3.3.3. After the configuration is complete, if ASBR2 receives Type 3 LSAs sent by ASBR4 with router ID 4.4.4.4, ASBR2 checks the DN bit and denies these Type 3 LSAs because the DN bit is set to 1.

Figure 1-73 Networking for fully meshed ASBRs in the inter-AS VPN Option A scenario

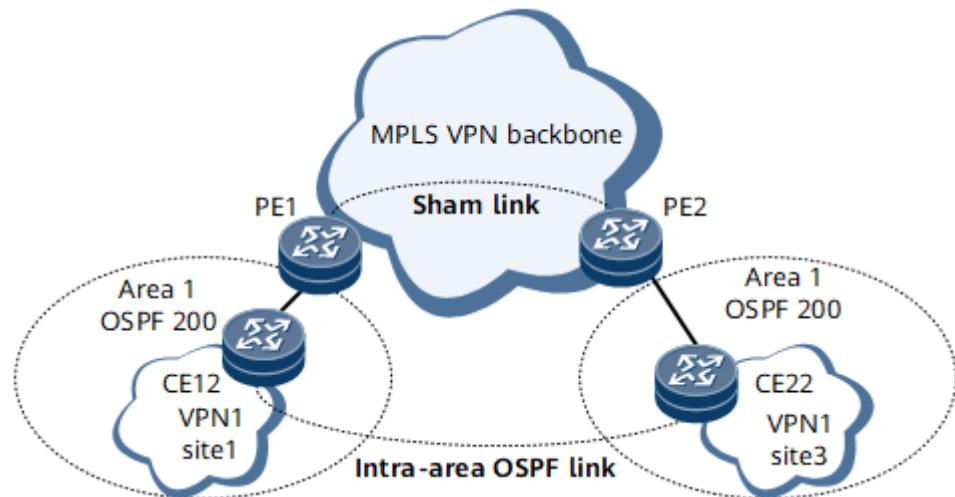

Sham Link

OSPF sham links are unnumbered P2P links between two PEs over an MPLS VPN backbone network.

Generally, BGP extended community attributes carry routing information over the MPLS VPN backbone between BGP peers. OSPF running on the other PE can use the routing information to generate inter-area routes from PEs to CEs.

Figure 1-74 OSPF Sham link

In [Figure 1-74](#), if an intra-area OSPF link exists between the network segments of local and remote CEs. Routes that pass through the intra-area route link and have higher priorities than inter-area routes that pass through the MPLS VPN backbone network. As a result, VPN traffic is always forwarded through the intra-area route instead of the backbone network. To prevent such a problem, an OSPF sham link can be established between PEs so that the routes that pass through the MPLS VPN backbone network also become OSPF intra-area routes and take precedence.

- A sham link is a link between two VPN instances. Each VPN instance contains the address of an end-point of a sham link. The address is a loopback address with the 32-bit mask in the VPN address space on the PE.
- After a sham link is established between two PEs, the PEs become neighbors on the sham link and exchange routing information.
- A sham link functions as a P2P link within an area. Users can select a route from the sham link and intra-area route link by adjusting the metric.

Multi-VPN-Instance CE

OSPF multi-instance generally runs on PEs. Devices that run OSPF multi-instance within user LANs are called Multi-VPN-Instance CEs (MCEs).

Compared with OSPF multi-instance running on PEs, MCEs have the following characteristics:

- MCEs do not need to support OSPF-BGP association.
- MCEs establish one OSPF instance for each service. Different virtual CEs transmit different services, which ensures LAN security at a low cost.
- MCEs implement different OSPF instances on a CE. The key to implementing MCEs is to disable loop detection and calculate routes directly. MCEs also use the received LSAs with the DN-bit 1 for route calculation.

OSPF NSSA

Background

As defined in OSPF, stub areas cannot import external routes. This prevents a large number of external routes from consuming router bandwidth and storage resources in the stub areas. If external routes need to be imported and resource consumption caused by external routes needs to be avoided, stub areas cannot meet the requirements. In this case, not-so-stubby areas (NSSAs) can be configured.

OSPF NSSA is a special type of area. There are many similarities between NSSAs and stub areas. However, different from stub areas, NSSAs can import AS external routes into the OSPF AS and advertise the imported routes in the OSPF AS without learning external routes from other areas on the OSPF network.

Related Concepts

- **N-bit**

A router uses the N-bit carried in a Hello packet to identify the area type that it supports. The same area type must be configured for all routers in an area. If routers have different area types, they cannot establish OSPF neighbor

relationships. Some non-Huawei devices set the N-bit in OSPF DD packets. To interwork with these non-Huawei devices, the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X can be configured to be compatible with these non-Huawei devices.

- **Type7 LSA**

Type 7 LSAs, which describe imported external routes, are introduced to support NSSAs. Type 7 LSAs are generated by an ASBR in an NSSA and advertised only within the NSSA. After an ABR in an NSSA receives Type 7 LSAs, it selectively translates Type 7 LSAs into Type 5 LSAs to advertise external routes to other areas on an OSPF network.

Principles

To advertise external routes imported by an NSSA to other areas, a translator must translate Type 7 LSAs into Type 5 LSAs. [Figure 1-75](#) shows the translation process.

- The propagate bit (P-bit) is used to notify a translator whether Type 7 LSAs need to be translated.
- By default, the translator is the ABR with the largest router ID in the NSSA.
- Only Type 7 LSAs with the P-bit set and a non-zero forwarding address (FA) can be translated into Type 5 LSAs. An FA indicates the address to which packets to a destination address will be forwarded.

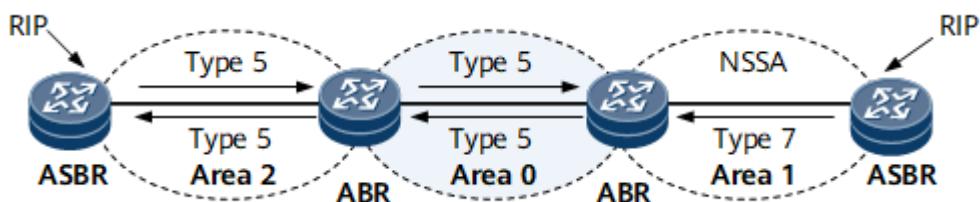

NOTE

An FA indicates the address to which packets to a destination address will be forwarded.

The loopback interface address in an area is preferentially selected as the FA. If no loopback interface exists, the address of the interface that is Up and has the smallest logical index in the area is selected as the FA.

- The P-bit is not set for default routes in Type 7 LSAs generated by an ABR.

Figure 1-75 NSSA

Advantages

Multiple ABRs may be deployed in an NSSA. To prevent routing loops caused by default routes, ABRs do not calculate the default routes advertised by each other.

OSPF Local MT

Background

When multicast and an MPLS TE tunnel are configured on a network and the TE tunnel is configured with IGP Shortcut, the outbound interface of the route

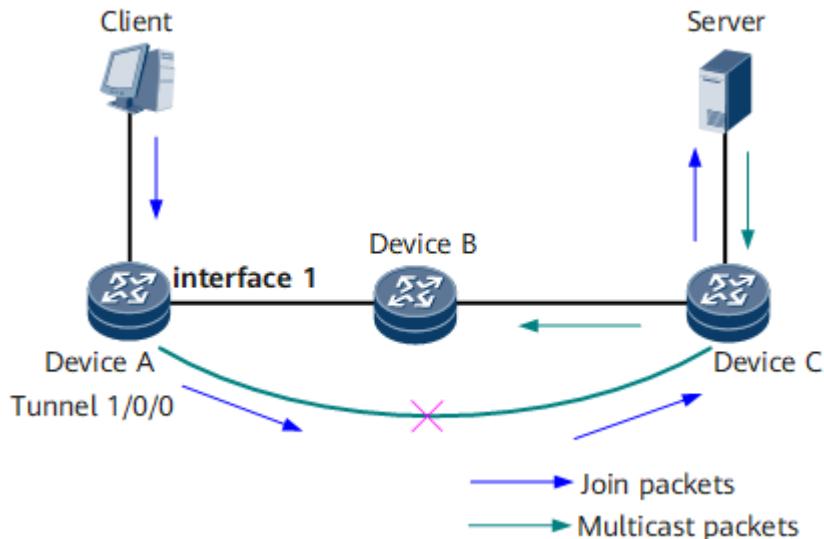

calculated by an IGP may be not an actual physical interface but a TE tunnel interface. The TE tunnel interface on the Device sends multicast Join messages over a unicast route to the multicast source address. The multicast Join messages are transparent to the Device spanned by the TE tunnel. As a result, the Device spanned by the TE tunnel cannot generate multicast forwarding entries.

To resolve the problem, configure OSPF local multicast topology (MT) to create a multicast routing table for multicast packet forwarding.

Implementation

Multicast and an MPLS TE tunnel are deployed on the network, and the TE tunnel is enabled with IGP Shortcut. As shown in [Figure 1-76](#), DeviceB is spanned by the TE tunnel and therefore does not create any multicast forwarding entry.

Figure 1-76 OSPF Local MT

Because the TE tunnel is unidirectional, multicast data packets sent from the multicast source are directly sent to the routers spanned by the tunnel through physical interfaces. These routers, however, do not have multicast forwarding entries. As a result, the multicast data packets are discarded, and services are unavailable.

After local MT is enabled, if the outbound interface of the calculated route is an IGP Shortcut TE tunnel interface, the route management (RM) module creates a separate Multicast IGP (MIGP) routing table for the multicast protocol, calculates the actual physical outbound interface for the route, and then adds the route to the MIGP routing table. Multicast then uses routes in the MIGP routing table to forward packets.

In [Figure 1-76](#), after the messages requesting to join a multicast group reach DeviceA, they are forwarded to DeviceB through interface 1. In this manner, DeviceB can correctly create the multicast forwarding table.

BFD for OSPF

Definition

Bidirectional Forwarding Detection (BFD) is a mechanism to detect communication faults between forwarding engines.

To be specific, BFD detects the connectivity of a data protocol along a path between two systems. The path can be a physical link, a logical link, or a tunnel.

In BFD for OSPF, a BFD session is associated with OSPF. The BFD session quickly detects a link fault and then notifies OSPF of the fault, which speeds up OSPF's response to network topology changes.

Purpose

A link fault or a topology change causes routers to recalculate routes. Routing protocol convergence must be as quick as possible to improve network availability. Link faults are inevitable, and therefore a solution must be provided to quickly detect faults and notify routing protocols.

BFD for Open Shortest Path First (OSPF) associates BFD sessions with OSPF. After BFD for OSPF is configured, BFD quickly detects link faults and notifies OSPF of the faults. BFD for OSPF accelerates OSPF response to network topology changes.

Table 1-28 describes OSPF convergence speeds before and after BFD for OSPF is configured.

Table 1-28 OSPF convergence speeds before and after BFD for OSPF is configured

Item	Link Fault Detection Mechanism	Convergence Speed
BFD for OSPF is not configured.	An OSPF Dead timer expires.	Second-level
BFD for OSPF is configured.	A BFD session goes Down.	Millisecond-level

Principles

Figure 1-77 BFD for OSPF

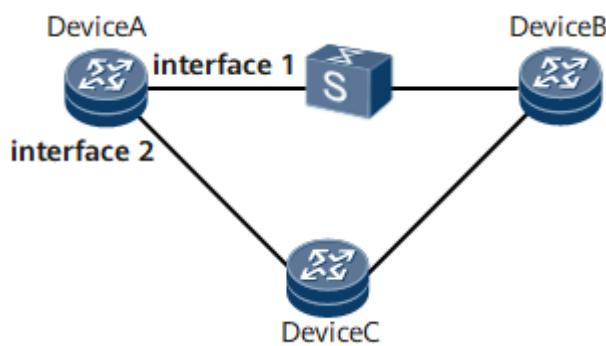

Figure 1-77 shows a typical network topology with BFD for OSPF configured. The principles of BFD for OSPF are described as follows:

1. OSPF neighbor relationships are established between these three routers.
2. After a neighbor relationship becomes Full, a BFD session is established.
3. The outbound interface on Device A connected to Device B is interface 1. If the link between Device A and Device B fails, BFD detects the fault and then notifies Device A of the fault.
4. Device A processes the event that a neighbor relationship goes Down and recalculates routes. The new route passes through Device C and reaches Device A, with interface 2 as the outbound interface.

OSPF GTSM

Definition

Generalized TTL security mechanism (GTSM) is a mechanism that protects services over the IP layer by checking whether the TTL value in an IP packet header is within a pre-defined range.

Purpose

On networks, attackers may simulate OSPF packets and keep sending them to a device. After receiving these packets, the device directly sends them to the control plane for processing without checking their validity if the packets are destined for the device. As a result, the control plane is busy processing these packets, resulting in high CPU usage.

GTSM is used to protect the TCP/IP-based control plane against CPU-utilization attacks, such as CPU-overload attacks.

Principles

GTSM-enabled devices check the TTL value in each received packet based on a configured policy. The packets that fail to pass the policy are discarded or sent to the control plane, which prevents the devices from possible CPU-utilization attacks. A GTSM policy involves the following items:

- Source address of the IP packet sent to the device
- VPN instance to which the packet belongs
- Protocol number of the IP packet (89 for OSPF)
- Source port number and destination port number of protocols above TCP/UDP
- Valid TTL range

GTSM is implemented as follows:

- For directly connected OSPF neighbors, the TTL value of the unicast protocol packets to be sent is set to 255.
- For multi-hop neighbors, a reasonable TTL range is defined.

The applicability of GTSM is as follows:

- GTSM takes effect on unicast packets rather than multicast packets. This is because the TTL value of multicast packets can only be 255, and therefore GTSM is not needed to protect against multicast packets.
- GTSM does not support tunnel-based neighbors.

OSPF Smart-discover

Definition

Hello packets are periodically sent on OSPF interfaces of routers. By exchanging Hello packets, the routers establish and maintain the neighbor relationship, and elect the DR and the Backup Designated Router (BDR) on the multiple-access network (broadcast or NBMA network). OSPF uses a Hello timer to control the interval at which Hello packets are sent. A router can send Hello packets again only after the Hello timer expires. Neighbors keep waiting to receive Hello packets until the Hello timer expires. This process delays the establishment of OSPF neighbor relationships or election of the DR and the BDR.

Enabling Smart-discover can solve the preceding problem.

Table 1-29 Processing differences with and without Smart-discover

With or Without Smart-discover	Processing
Without Smart-discover	<ul style="list-style-type: none">• Hello packets are sent only when the Hello timer expires.• Hello packets are sent at the Hello interval.• Neighbors keep waiting to receive Hello packets within the Dead interval.
With Smart-discover	<ul style="list-style-type: none">• Hello packets are sent directly regardless of whether the Hello timer expires.• Neighbors can receive packets and change the state immediately.

Principles

In the following situations, Smart-discover-enabled interfaces can send Hello packets to neighbors regardless of whether the Hello timer expires:

- On broadcast or NBMA networks, neighbor relationships can be established and a DR and a BDR can be elected rapidly.
 - The neighbor status becomes 2-way for the first time or returns to Init from 2-way or a higher state.
 - The interface status of the DR or BDR on a multiple-access network changes.
- On P2P or P2MP networks, neighbor relationships can be established rapidly. The establishment of neighbor relationships on a P2P or P2MP network is the same as that on a broadcast or NBMA network.

OSPF-BGP Synchronization

Background

When a new device is deployed on a network or a device is restarted, network traffic may be lost during BGP route convergence because IGP routes converge more quickly than BGP routes.

OSPF-BGP synchronization can address this problem.

Purpose

If a backup link exists, BGP traffic may be lost during traffic switchback because BGP routes converge more slowly than OSPF routes do.

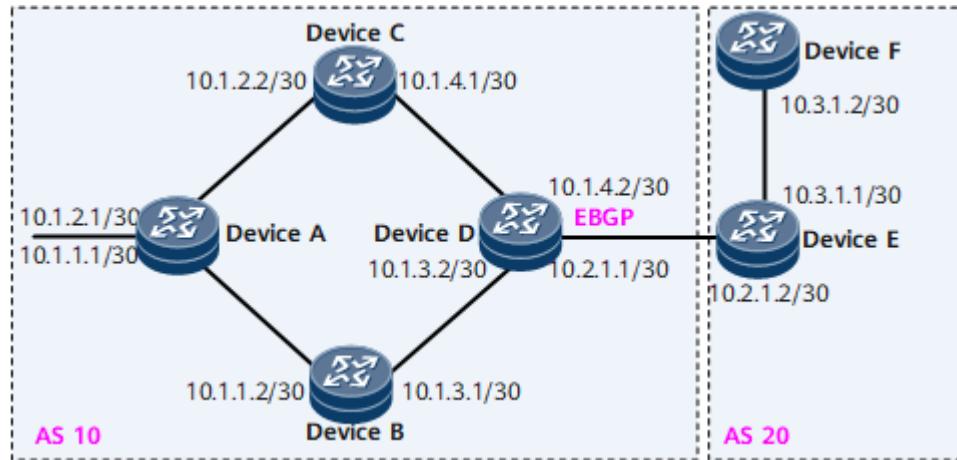

In **Figure 1-78**, Device A, Device B, Device C, and Device D run OSPF and establish IBGP connections. Device C functions as the backup of Device B. When the network is stable, BGP and OSPF routes converge completely on the router.

In most cases, traffic from Device A to 10.3.1.0/30 passes through Device B. If Device B fails, traffic is switched to Device C. After Device B recovers, traffic is switched back to Device B. During this process, packet loss occurs.

Consequently, convergence of OSPF routes is complete whereas BGP route convergence is still going on. As a result, Device B does not have the route to 10.3.1.0/30.

When packets from Device A to 10.3.1.0/30 reach Device B, Device B discards them because Device B does not have the route to 10.3.1.0/30.

Figure 1-78 Networking for OSPF-BGP synchronization

Principles

If OSPF-BGP synchronization is configured on a device, the device remains as a stub router during the set synchronization period. During this period, the link metric in the LSA advertised by the device is set to the maximum value (65535), instructing other OSPF routers not to use it as a transit router for data forwarding.

In [Figure 1-78](#), OSPF-BGP synchronization is enabled on Router B. In this situation, before BGP route convergence is complete, Device A keeps forwarding data through Device C rather than Device B until BGP route convergence on Device B is complete.

LDP-IGP Synchronization

Background

LDP-IGP synchronization is used to synchronize the status between LDP and an IGP to minimize the traffic loss time if a network fault triggers the LDP and IGP switching.

On a network with active and standby links, if the active link fails, IGP routes and an LSP are switched to the standby link. After the active link recovers, IGP routes are switched back to the active link before LDP convergence is complete. In this case, the LSP along the active link takes time to make preparations, such as adjacency restoration, before being established. As a result, LSP traffic is discarded. If an LDP session or adjacency between nodes fails on the active link, the LSP along the active link is deleted. However, the IGP still uses the active link, and as a result, LSP traffic cannot be switched to the standby link, and is continuously discarded.

NOTE

LDP-IGP synchronization supports OSPFv2 and IS-IS (IPv4).

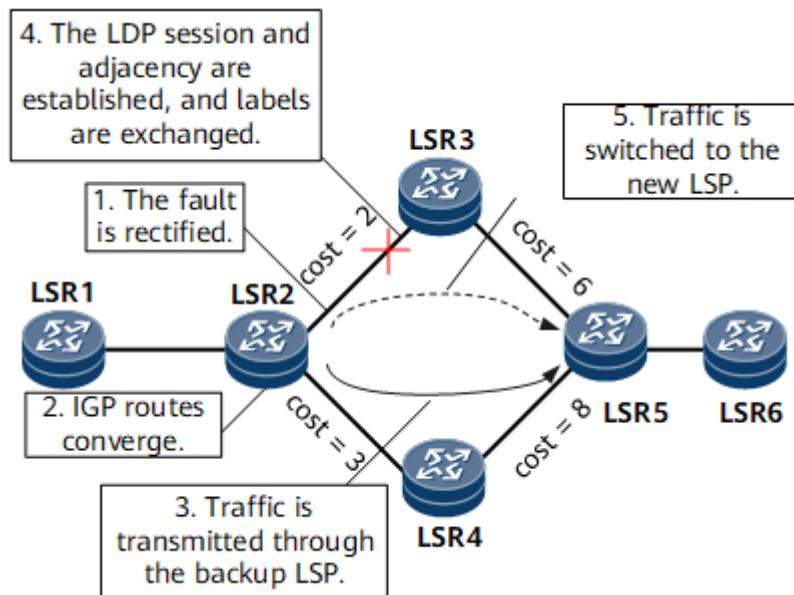

On a network enabled with LDP-IGP synchronization, an IGP keeps advertising the maximum cost of an IGP route over the new active link to delay IGP route convergence until LDP converges. That is, before the LSP of the active link is established, the LSP of the standby link is retained so that the traffic continues to be forwarded through the standby link. The standby LSP is torn down only after the active LSP is established successfully.

LDP-IGP synchronization involves the following timers:

- Hold-max-cost timer
- Delay timer

Implementation

Figure 1-79 Switchback in LDP-IGP synchronization

- The network shown in **Figure 1-79** has active and standby links. When the active link recovers from a fault, traffic is switched from the standby link back to the active link. During the traffic switchback, the standby LSP cannot be used, and a new LSP cannot be set up over the active link once IGP route convergence is complete. This causes a traffic interruption for a short period of time. To prevent this problem, LDP-IGP synchronization can be configured to delay IGP route switchback until LDP convergence is complete. Before convergence of the active LSP completes, the standby LSP is retained, so that the traffic continues to be forwarded through the standby LSP until the active LSP is successfully established. Then the standby LSP is torn down. The detailed process is as follows:
 - a. The link fault is rectified.
 - b. An LDP session is set up between LSR2 and LSR3. The IGP advertises the maximum cost of the active link to delay the IGP route switchback.
 - c. Traffic is still forwarded along the standby LSP.
 - d. The LDP session is set up. Label messages are exchanged to notify the IGP to start synchronization.
 - e. The IGP advertises the normal cost of the active link, and its routes converge to the original forwarding path. The LSP is reestablished and entries are delivered to the forwarding table (within milliseconds).
- If an LDP session between nodes fails on the active link, the LSP along the active link is deleted. However, the IGP still uses the active link, and as a result, LSP traffic cannot be switched to the standby link, and is continuously discarded. To prevent this problem, you can configure LDP-IGP synchronization. If an LDP session fails, LDP notifies an IGP of the failure. The IGP advertises the maximum cost of the failed link, which enables the route to switch from the active link to the standby link. In addition to the LSP

switchover from the primary LSP to the backup LSP, LDP-IGP synchronization is implemented. The process of LDP-IGP synchronization is as follows:

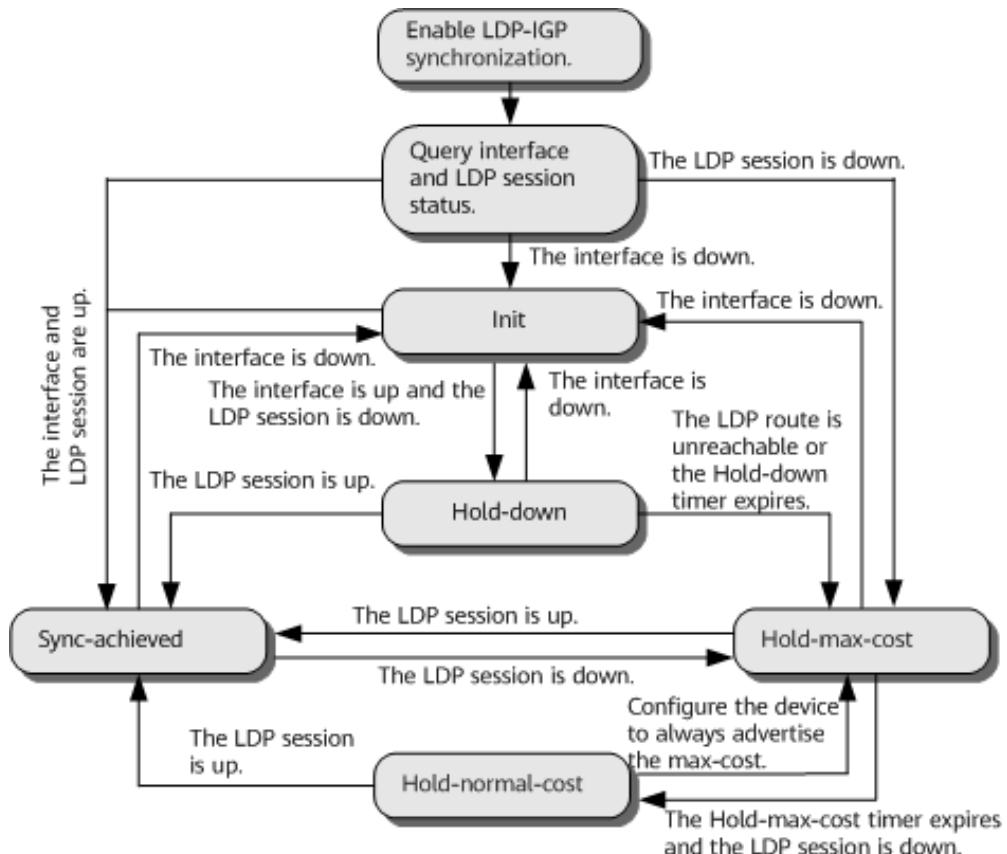

- a. An LDP session between two nodes on the active link fails.
- b. LDP notifies the IGP of the failure in the session over the active link. The IGP then advertises the maximum cost along the active link.
- c. The IGP route switches to the standby link.
- d. An LSP is set up over the standby link, and then forwarding entries are delivered.

To prevent repeated failures in LDP session reestablishment, you can use the Hold-max-cost timer to configure the device to always advertise the maximum cost, so that traffic is transmitted along the standby link before the LDP session is reestablished on the active link.

- LDP-IGP synchronization state transition mechanism

After LDP-IGP synchronization is enabled on an interface, the IGP queries the status of the interface and LDP session according to the process shown in **Figure 1-80**, enters the corresponding state according to the query result, and then transits the state according to **Figure 1-80**.

Figure 1-80 LDP-IGP synchronization state transition

NOTE

The preceding states may slightly vary between different IGPs.

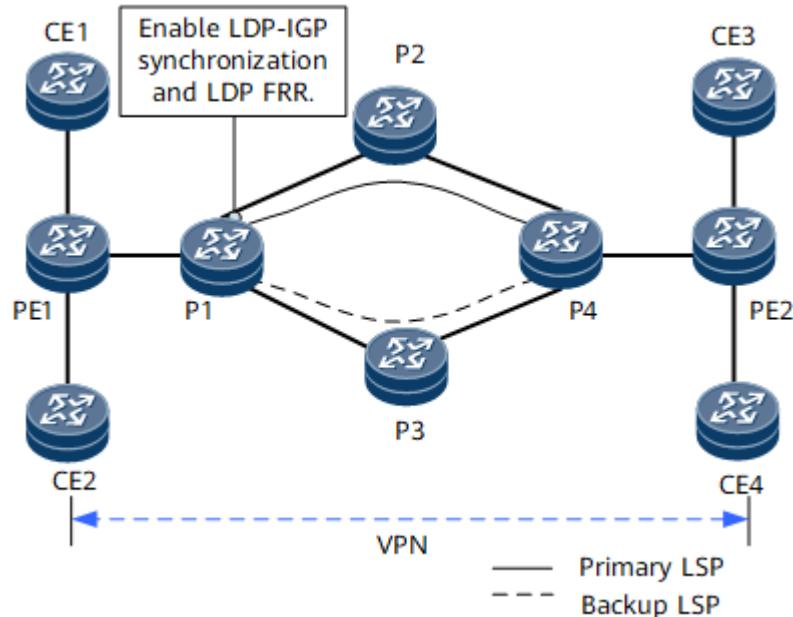

- When OSPF is used as the IGP, the state transition is the same as that in [Figure 1-80](#).
- When IS-IS is used as the IGP, the Hold-normal-cost state does not exist. After the Hold-max-cost timer expires, IS-IS advertises the normal link cost, but the Hold-max-cost state is displayed even though this state is nonexistent.

Usage Scenario

LDP-IGP synchronization applies to the following scenario:

On the network shown in [Figure 1-81](#), an active link and a standby link are established. LDP-IGP synchronization and LDP FRR are deployed.

Figure 1-81 LDP-IGP synchronization scenario

Benefits

Packet loss is reduced during an active/standby link switchover, improving network reliability.

OSPF Fast Convergence

OSPF fast convergence is an extended feature of OSPF to speed up the convergence of routes. It includes the following components:

- Partial Route Calculation (PRC): calculates only those routes which have changed when the network topology changes.
- An OSPF intelligent timer: can dynamically adjust its value based on the user's configuration and the interval at which an event is triggered, such as the route calculation interval, which ensures rapid and stable network operation.

OSPF intelligent timer uses the exponential backoff technology so that the value of the timer can reach the millisecond level.

PRC

When a node in a network topology changes, the Dijkstra algorithm needs to recalculate all routes on the network. This calculation takes a long time and consumes a large number of CPU resources, which affects the convergence speed on the entire network. However, PRC uses only the nodes that have changed to recalculate routes, thereby decreasing CPU usage.

In route calculation, a leaf represents a route, and a node represents a device. Either an SPT change or a leaf change causes a routing information change. The SPT change is irrelevant to the leaf change. PRC processes routing information as follows:

- If the SPT changes, PRC calculates all the leaves only on the changed node.
- If the SPT remains unchanged, PRC calculates only the changed leaves.

For example, if a new route is imported, the SPT of the entire network remains unchanged. In this case, PRC updates only the interface route for this node, thereby reducing the CPU usage.

OSPF Intelligent Timer

On an unstable network, routes are calculated frequently, which consumes a great number of CPU resources. In addition, link-state advertisements (LSAs) that describe the unstable topology are generated and transmitted on the unstable network. Frequently processing such LSAs affects the rapid and stable operation of the entire network.

To speed up route convergence on the entire network, the OSPF intelligent timer controls route calculation, LSA generation, and LSA receiving.

The OSPF intelligent timer works as follows:

- On a network where routes are calculated repeatedly, the OSPF intelligent timer dynamically adjusts the route calculation based on user's configuration and the exponential backoff technology. The number of route calculation times and the CPU resource consumption are decreased. Routes are calculated after the network topology stabilizes.
- On an unstable network, if a router generates or receives LSAs due to frequent topology changes, the OSPF intelligent timer can dynamically adjust the interval. No LSAs are generated or processed within an interval, which prevents invalid LSAs from being generated and advertised on the entire network.

OSPF Neighbor Relationship Flapping Suppression

OSPF neighbor relationship flapping suppression works by delaying OSPF neighbor relationship reestablishment or setting the link cost to the maximum value.

Background

If an interface carrying OSPF services frequently alternates between up and down, frequent neighbor relationship flapping will occur. During the flapping, OSPF

frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, OSPF services, and other OSPF-dependent services, such as LDP and BGP. OSPF neighbor relationship flapping suppression can address this problem by delaying OSPF neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

Related Concepts

Flapping-event: reported when the status of a neighbor relationship on an interface last changes from Full to a non-Full state. The flapping-event triggers flapping detection.

Flapping-count: number of times flapping has occurred.

Detecting-interval: detection interval. The interval is used to determine whether to trigger a valid flapping_event.

Threshold: flapping suppression threshold. When the flapping_count reaches or exceeds **threshold**, flapping suppression takes effect.

Resume-interval: interval for exiting neighbor relationship flapping suppression. If the interval between two successive valid flapping_events is longer than **resume-interval**, the flapping_count is reset.

Implementation

Flapping detection

Each OSPF interface on which OSPF neighbor relationship flapping suppression is enabled starts a flapping counter. If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than **detecting-interval**, a valid flapping_event is recorded, and the flapping_count increases by 1. When the flapping_count reaches or exceeds **threshold**, flapping suppression takes effect. If the interval between two successive neighbor status changes from Full to a non-Full state is longer than **resume-interval**, the flapping_count is reset.

The **detecting-interval**, **threshold**, and **resume-interval** are configurable.

The value of **resume-interval** must be greater than that of **detecting-interval**.

Flapping suppression

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during Hold-down suppression, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: In this mode, the link cost is set to the maximum value (65535) within a period of time to prevent service traffic from passing through flapping links.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. The mode and suppression duration can be changed manually.

If an attack causes frequent neighbor relationship flapping, Hold-down mode can minimize the impact of the attack.

NOTE

When an interface enters the flapping suppression state, all neighbor relationships on the interface enter the state accordingly.

Exiting from flapping suppression

Interfaces exit from flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding OSPF process is reset.
- An OSPF neighbor is reset.
- A command is run to exit from flapping suppression.

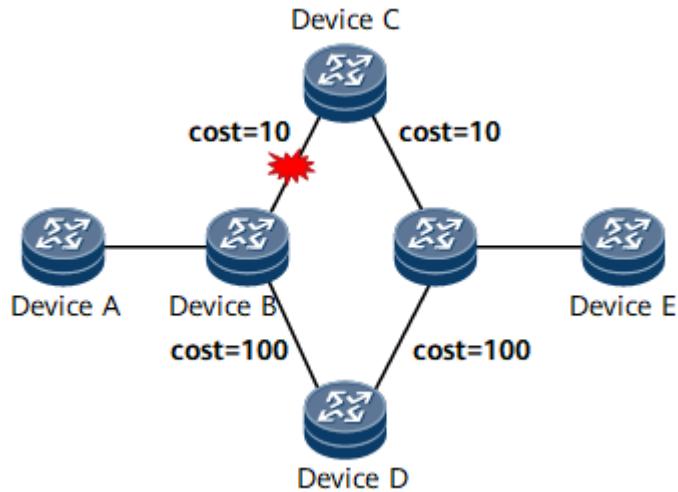

Typical Scenarios

Basic scenario

In [Figure 1-82](#), the traffic forwarding path is Device A -> Device B -> Device C -> Device E before a link failure occurs. After the link between Device B and Device C fails, the forwarding path switches to Device A -> Device B -> Device D -> Device E. If the neighbor relationship between Device B and Device C frequently flaps at the early stage of the path switchover, the forwarding path will be switched frequently, causing traffic loss and affecting network stability. If the neighbor relationship flapping meets suppression conditions, flapping suppression takes effect.

- If flapping suppression works in Hold-down mode, the neighbor relationship between Device B and Device C is prevented from being reestablished during the suppression period, in which traffic is forwarded along the path Device A -> Device B -> Device D -> Device E.
- If flapping suppression works in Hold-max-cost mode, 65535 is used as the cost of the link between Device B and Device C during the suppression period, and traffic is forwarded along the path Device A -> Device B -> Device D -> Device E.

Figure 1-82 Flapping suppression in a basic scenario

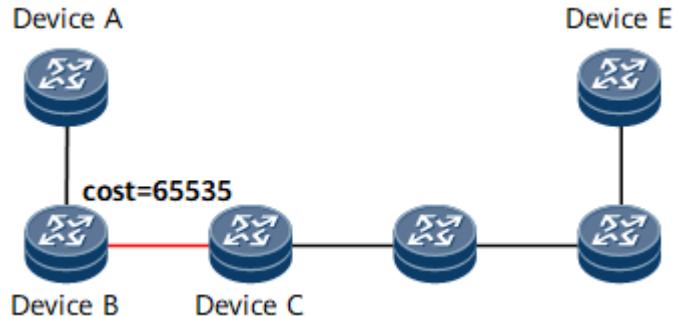

Single-forwarding path scenario

When only one forwarding path exists on the network, the flapping of the neighbor relationship between any two devices on the path will interrupt traffic forwarding. In [Figure 1-83](#), the traffic forwarding path is Device A -> Device B -> Device C -> Device E. If the neighbor relationship between Device B and Device C flaps, and the flapping meets suppression conditions, flapping suppression takes effect. However, if the neighbor relationship between Device B and Device C is prevented from being reestablished, the whole network will be divided. Therefore, Hold-max-cost mode (rather than Hold-down mode) is recommended. If flapping suppression works in Hold-max-cost mode, 65535 is used as the cost of the link between Device B and Device C during the suppression period. After the network stabilizes and the suppression timer expires, the link is restored.

NOTE

By default, the Hold-max-cost mode takes effect.

Figure 1-83 Flapping suppression in a single-forwarding path scenario

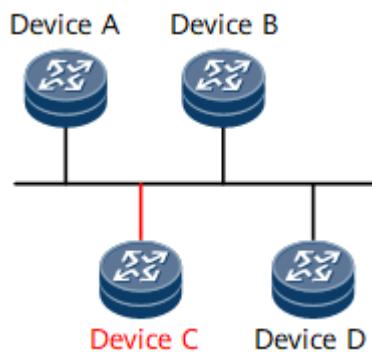

Broadcast scenario

In [Figure 1-84](#), four devices are deployed on the same broadcast network using switches, and the devices are broadcast network neighbors. If Device C flaps due to a link failure, and Device A and Device B were deployed at different time

(Device A was deployed earlier for example) or the flapping suppression parameters on Device A and Device B are different, Device A first detects the flapping and suppresses Device C. Consequently, the Hello packets sent by Device A do not carry Device C's router ID. However, Device B has not detected the flapping yet and still considers Device C a valid node. As a result, the DR candidates identified by Device A are Device B and Device D, whereas the DR candidates identified by Device B are Device A, Device C, and Device D. Different DR candidates result in a different DR election result, which may lead to route calculation errors. In scenarios where an interface has multiple neighbors, such as on a broadcast, P2MP, or NBMA network, all neighbors on the interface are suppressed if the last flapping event that the neighbor status on the interface becomes ExStart or Down is detected (flapping detection cannot be performed by neighbor). Specifically, if Device C flaps, Device A, Device B, and Device D on the broadcast network are all suppressed. After the network stabilizes and the suppression timer expires, Device A, Device B, and Device D are restored to normal status.

Figure 1-84 Flapping suppression on a broadcast network

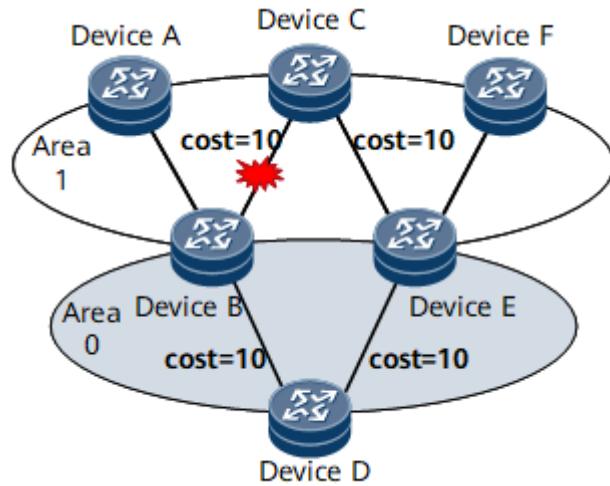

Multi-area scenario

In **Figure 1-85**, Device A, Device B, Device C, Device E, and Device F are connected in area 1, and Device B, Device D, and Device E are connected in backbone area 0. Traffic from Device A to Device F is preferentially forwarded along an intra-area route, and the forwarding path is Device A -> Device B -> Device C -> Device E -> Device F. If the neighbor relationship between Device B and Device C flaps and the flapping meets suppression conditions, flapping suppression takes effect in the default mode (Hold-max-cost). However, the forwarding path remains unchanged (Device A -> Device B -> Device C -> Device E -> Device F) after the neighbor flapping occurs because intra-area routes take precedence over inter-area routes during route selection regardless of costs according to OSPF route selection rules. The Hold-max-cost mode cannot suppress traffic path switching in this case. To prevent traffic loss in multi-area scenarios, configure Hold-down mode to prevent the neighbor relationship between Device B and Device C from being reestablished during the suppression period. During this period, traffic is forwarded along the path Device A -> Device B -> Device D -> Device E -> Device F.

NOTE

By default, the Hold-max-cost mode takes effect. The mode can be changed to Hold-down manually.

Figure 1-85 Flapping suppression in a multi-area scenario

Scenario with both LDP-IGP synchronization and OSPF neighbor relationship flapping suppression configured

In [Figure 1-86](#), if the link between PE1 and P1 fails, an LDP LSP switchover is implemented immediately, causing the original LDP LSP to be deleted before a new LDP LSP is established. To prevent traffic loss, LDP-IGP synchronization needs to be configured. With LDP-IGP synchronization, 65535 is used as the cost of the new LSP to be established. After the new LSP is established, the original cost takes effect. Consequently, the original LSP is deleted, and LDP traffic is forwarded along the new LSP.

LDP-IGP synchronization and OSPF neighbor relationship flapping suppression work in either Hold-down or Hold-max-cost mode. If both functions are configured, Hold-down mode takes precedence over Hold-max-cost mode, followed by the configured link cost. [Table 1-30](#) lists the suppression modes that take effect in different situations.

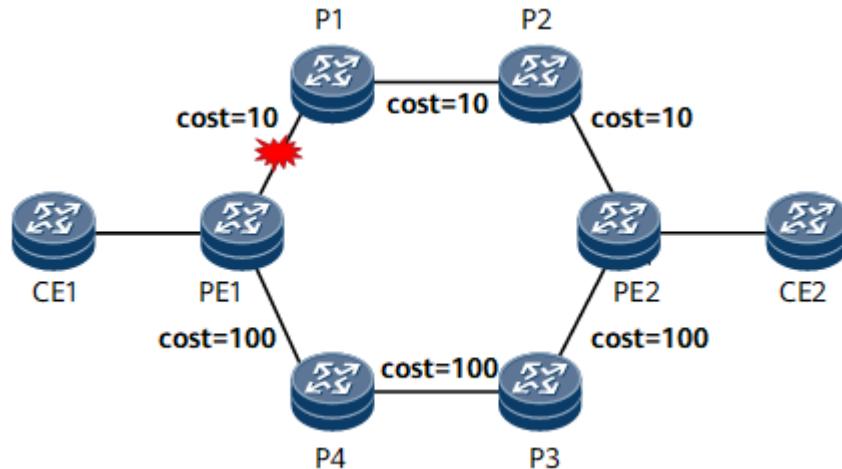

Table 1-30 Principles for selecting the suppression modes that take effect in different situations

LDP-IGP Synchronization/OSPF Neighbor Relationship Flapping Suppression Mode	LDP-IGP Synchronization Hold-down Mode	LDP-IGP Synchronization Hold-max-cost Mode	Exited from LDP-IGP Synchronization Suppression
OSPF Neighbor Relationship Flapping Suppression Hold-down Mode	Hold-down	Hold-down	Hold-down

LDP-IGP Synchronization/OSPF Neighbor Relationship Flapping Suppression Mode	LDP-IGP Synchronization Hold-down Mode	LDP-IGP Synchronization Hold-max-cost Mode	Exited from LDP-IGP Synchronization Suppression
OSPF Neighbor Relationship Flapping Suppression Hold-max-cost Mode	Hold-down	Hold-max-cost	Hold-max-cost
Exited from OSPF Neighbor Relationship Flapping Suppression	Hold-down	Hold-max-cost	Exited from LDP-IGP synchronization and OSPF neighbor relationship flapping suppression

For example, the link between PE1 and P1 frequently flaps in [Figure 1-86](#), and both LDP-IGP synchronization and OSPF neighbor relationship flapping suppression are configured. In this case, the suppression mode is selected based on the preceding principles. No matter which mode (Hold-down or Hold-max-cost) is selected, the forwarding path is PE1 -> P4 -> P3 -> PE2.

Figure 1-86 Scenario with both LDP-IGP synchronization and OSPF neighbor relationship flapping suppression configured

Scenario with both bit-error-triggered protection switching and OSPF neighbor relationship flapping suppression configured

Bit-error-triggered protection switching is used to protect link quality. If link quality detection detects that the link quality is poor and the bit error rate (BER) is high, a bit error event is reported. User services carried on the link with a high BER are adversely affected. Therefore, user traffic needs to be switched to other links. After receiving a bit error event, OSPF adjusts the interface cost to the maximum value (65535). Then, OSPF recalculates routes and switch service traffic to the backup link. If both bit-error-triggered protection switching and OSPF neighbor relationship flapping suppression are configured, they both take effect. Hold-down mode takes precedence over Hold-max-cost mode, followed by the configured link cost.

OSPF Flush Source Tracing

Context

If network-wide OSPF LSA flush causes network instability, source tracing must be implemented as soon as possible to locate and isolate the fault source. However, OSPF itself does not support source tracing. A conventional solution is to isolate nodes one by one until the fault source is located, but the process is complex and time-consuming and may compromise network services. To solve the preceding problem, OSPF introduces a proprietary protocol, namely, the source tracing protocol. This protocol supports the flooding of flush source information. When the preceding problem occurs, you can quickly query the flush source information on any device on the network to quickly locate the fault source.

Related Concepts

Source tracing

A mechanism that helps locate the device that flushes OSPF LSAs. This feature has the following characteristics:

- Uses a new UDP port. Source tracing packets are carried by UDP packets, and the UDP packets also carry the OSPF LSAs flushed by the current device and are flooded hop by hop based on the OSPF topology.
- Depends on OSPF neighbors for flooding and forwards packets along UDP channels, which are independent of the channels used to transmit OSPF packets. Therefore, this protocol facilitates incremental deployment. In addition, source tracing does not affect the devices with the related UDP port disabled.
- Supports query of the node that flushed LSAs on any of the devices after source tracing packets are flooded on the network, which speeds up fault locating and faulty node isolation.

Flush

Network-wide OSPF LSAs are deleted.

PS-Hello packets

Packets used to negotiate the OSPF flush source tracing capability between OSPF neighbors.

PS-LSA

When a device flushes an OSPF LSA, it generates a PS-LSA carrying information about the device and brief information about the OSPF LSA.

PS-LSU packets

OSPF flush LSA source tracing packets that carry PS-LSAs.

PS-LSU ACK packets

Acknowledgment packets used to improve OSPF flush source tracing packets.

OSPF flush source tracing port

ID of the UDP port that receives and sends OSPF flush source tracing packets. The ID is configurable.

Fundamentals

The implementation of OSPF flush source tracing is as follows:

1. Source tracing capability negotiation

After an OSPF neighbor relationship is established between two devices, they need to negotiate the source tracing capability through PS-Hello packets.

2. PS-LSA generation and flooding

When a device flushes an OSPF LSA, it generates a PS-LSA carrying information about the device and brief information about the OSPF LSA, adds the PS-LSA to a PS-LSU packet, and floods the PS-LSU packet to source tracing-capable neighbors, which helps other devices locate the fault source and perform isolation.

NOTE

Only router-LSAs, network-LSAs, and inter-area-router-LSAs can be flushed. Therefore, a device generates a PS-LSA only when it flushes a router-LSA, network-LSA, or inter-area-router-LSA.

Source tracing capability negotiation

The source tracing protocol uses UDP to carry source tracing packets and listens to the UDP port, which is used to receive and send source tracing packets. If a source tracing-capable Huawei device sends source tracing packets to a source tracing-incapable Huawei device or non-Huawei device, the source tracing-capable Huawei device may be incorrectly identified as an attacker. Therefore, the source tracing capability needs to be negotiated between the devices. In addition, the source tracing-capable device needs to send source tracing information on behalf of the source tracing-incapable device, which also requires negotiation.

Source tracing capability negotiation depends on OSPF neighbor relationships. Specifically, after an OSPF neighbor relationship is established, the local device initiates source tracing capability negotiation. [Figure 1-87](#) shows the negotiation process.

Figure 1-87 Source tracing capability negotiation

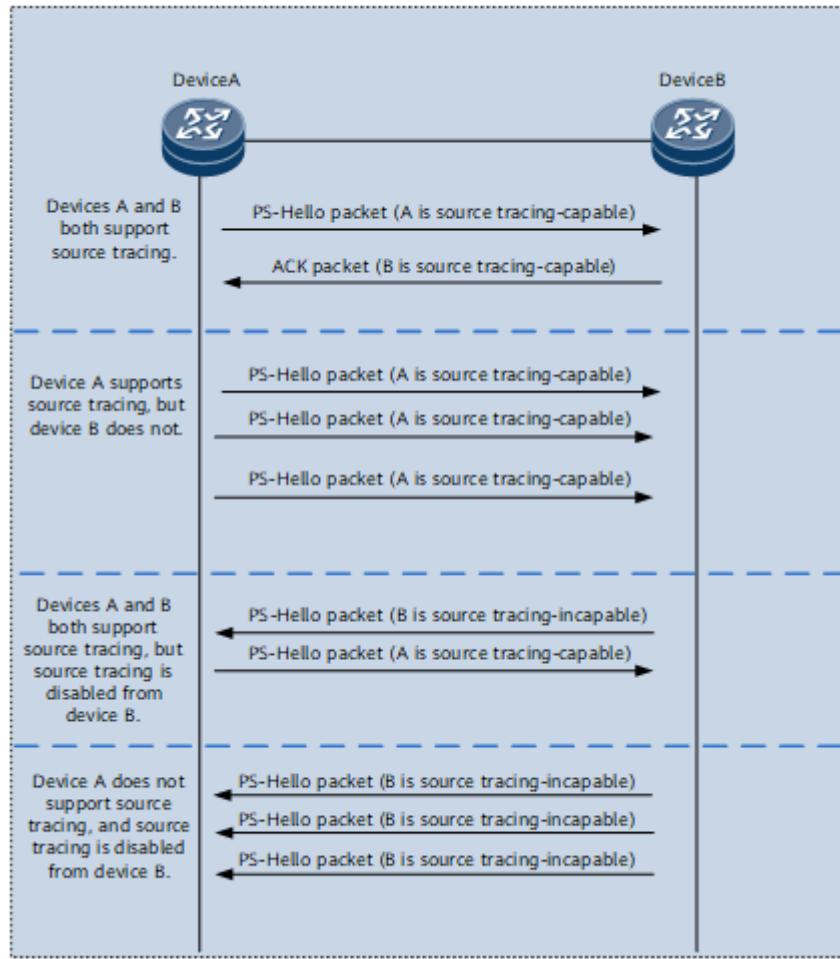

Table 1-31 Source tracing capability negotiation

Whether Source Tracing Is Supported	Source Tracing Capability Negotiation Process
Devices A and B both support source tracing.	<ol style="list-style-type: none"> 1. DeviceA sends a PS-Hello packet to notify its source tracing capability. 2. Upon reception of the PS-Hello packet, DeviceB sets the source tracing field for DeviceA and replies with an ACK packet to notify its source tracing capability to DeviceA. 3. Upon reception of the ACK packet, DeviceA sets the source tracing field for DeviceB, and does not retransmit the PS-Hello packet.

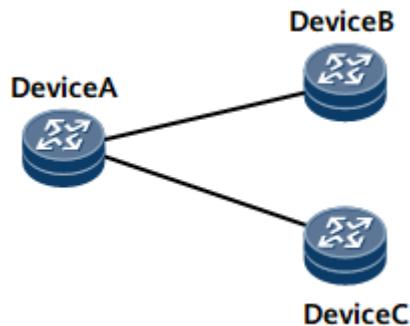

Whether Source Tracing Is Supported	Source Tracing Capability Negotiation Process
DeviceA supports source tracing, but DeviceB does not.	<ol style="list-style-type: none"> 1. DeviceA sends a PS-Hello packet to notify its source tracing capability. 2. DeviceA fails to receive an ACK packet from DeviceB after 10s elapses and retransmits the PS-Hello packet. A maximum of two retransmissions are allowed. After DeviceA fails to receive an ACK packet from DeviceB after the PS-Hello packet is retransmitted twice, DeviceA considers that DeviceB does not support source tracing.
Devices A and B both support source tracing, but source tracing is disabled from DeviceB.	<ol style="list-style-type: none"> 1. After source tracing is disabled from DeviceB, DeviceB sends a PS-Hello packet to notify its source tracing incapability. 2. Upon reception of the PS-Hello packet from DeviceB, DeviceA replies with an ACK packet that carries the source tracing capability. 3. Upon reception of the ACK packet from DeviceA, DeviceB considers the capability negotiation complete and disables the UDP port.
DeviceA does not support source tracing, and source tracing is disabled from DeviceB.	<ol style="list-style-type: none"> 1. After source tracing is disabled from DeviceB, DeviceB sends a PS-Hello packet to notify its source tracing incapability. 2. DeviceB fails to receive an ACK packet from DeviceA after 10s elapses and retransmits the PS-Hello packet. A maximum of two retransmissions are allowed. After two retransmissions, DeviceB considers the capability negotiation complete and disables the UDP port.

PS-LSA generation and flooding

PS-LSA: carries information about the node that flushed OSPF LSAs.

- If a device flushes an LSA, it generates and floods a PS-LSA to source tracing-capable neighbors.
- If a device receives a flush LSA from a source tracing-incapable neighbor, the device generates and floods a PS-LSA to source tracing-capable neighbors. If a device receives the same flush LSA (with the same LSID and sequence number) from more than one source tracing-incapable neighbor, the device generates only one PS-LSA.
- If a device flushes a router-LSA, network-LSA, or inter-area-router-LSA, it generates a PS-LSA, adds the PS-LSA to a PS-LSU packet, and floods the PS-LSU packet to all source tracing-capable neighbors.

Figure 1-88 PS-LSA generation rules

PS-LSA generation rules

- When DeviceA flushes a router-LSA, network-LSA, or inter-area-router-LSA, it generates a PS-LSA in which the **Flush Router** field is its router ID and the **Neighbor Router** field is 0, and adds the PS-LSA to the queue where packets are to be sent to all source tracing-capable neighbors.
- After DeviceA receives the flush LSA from source tracing-incapable DeviceB, DeviceA generates a PS-LSA in which the **Flush Router** field is its router ID and the **Neighbor Router** field is the router ID of DeviceB, and adds the PS-LSA to the queue where packets are to be sent to all source tracing-capable neighbors.
- After DeviceA receives the flush LSA from DeviceB, followed by the same flush LSA sent by DeviceC, DeviceA generates a PS-LSA in which the **Flush Router** field is its router ID and the **Neighbor Router** field is the router ID of DeviceB, and adds the PS-LSA to the queue where packets are to be sent to all source tracing-capable neighbors. No PS-LSA is generated in response to the flush LSA received from DeviceC.

PS-LSU packet sending rules

- During neighbor relationship establishment, a device initializes the sequence number of the PS-LSU packet of the neighbor. When the device replies with a PS-LSU packet, it adds the sequence number of the PS-LSU packet of the neighbor. During PS-LSU packet retransmission, the sequence number remains unchanged. After the device receives a PS-LSU ACK packet with the same sequence number, it increases the sequence number of the neighbor's PS-LSU packet by 1.
- The neighbor manages the PS-LSA sending queue. When a PS-LSA is added to the queue which was empty, the neighbor starts a timer. After the timer expires, the neighbor adds the PS-LSA to a PS-LSU packet, sends the packet to its neighbor, and starts another timer to wait for a PS-LSU ACK packet.
- After the PS-LSU ACK timer expires, the PS-LSU packet is retransmitted.
- When the device receives a PS-LSU ACK packet with a sequence number same as that in the neighbor record, the device clears PS-LSAs from the neighbor queue, and sends another PS-LSU packet after the timer expires.
 - If the sequence number of a received PS-LSU ACK packet is less than that in the neighbor record, the device ignores the packet.
 - If the sequence number of a received PS-LSU ACK packet is greater than that in the neighbor record, the device discards the packet.

 NOTE

PS-LSU packet sending is independent among neighbors.

PS-LSU packet receiving rules

- When a device receives a PS-LSU packet from a neighbor, the neighbor records the sequence number of the packet and replies with a PS-LSU ACK packet.
- When the device receives a PS-LSU packet with the sequence number the same as that in the neighbor record, the device discards the PS-LSU packet.
- After the device parses a PS-LSU packet, it adds the PS-LSA in the packet to its LSDB. The device also checks whether the PS-LSA is newer than the corresponding PS-LSA in its LSDB.
 - If the received PS-LSA is newer, the device floods it to other neighbors.
 - If the received PS-LSA is the same as the corresponding local one, the device does not process the received PS-LSA.
 - If the received PS-LSA is older, the device floods the corresponding local one to the neighbor.
- If the device receives a PS-LSU packet from a neighbor and the neighbor does not support source tracing, the device modifies the neighbor status as source tracing capable.

Source Tracing Security

The source tracing protocol uses a UDP port to receive and send source tracing packets. Therefore, the security of the port must be taken into consideration.

The source tracing protocol inevitably increases packet receiving and sending workload and intensifies bandwidth pressure. To minimize its impact on other protocols, the number of source tracing packets must be controlled.

The following security measures are available:

Table 1-32 Security measures for source tracing

Security Measures for Source Tracing	Fundamentals
Authentication	Source tracing is embedded in OSPF, inherits existing OSPF configuration parameters, and uses OSPF authentication parameters to authenticate packets.

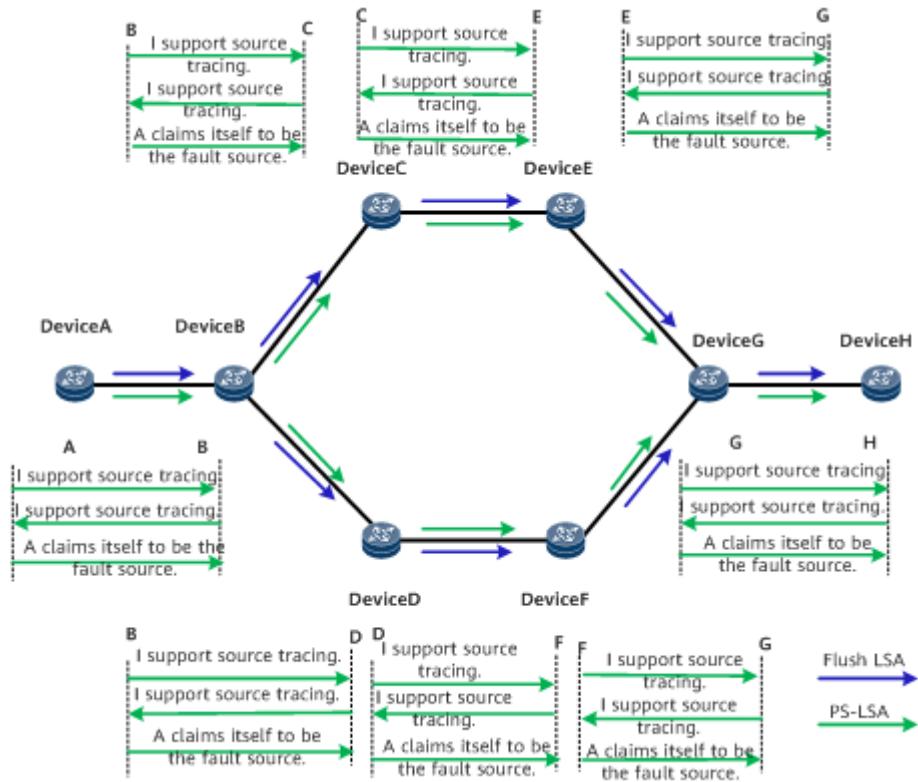

Security Measures for Source Tracing	Fundamentals
GTSM	<p>GTSM is a security mechanism that checks whether the time to live (TTL) value in each received IP packet header is within a pre-defined range.</p> <p>Source tracing packets can only be flooded as far as one hop. Therefore, GTSM can be used to check such packets by default.</p> <ul style="list-style-type: none">• When a device sends a packet, it sets the TTL of the packet to 255.• If the TTL is not 254 when the packet is received, the packet will be discarded.
CPU-CAR	<p>Interface boards can check the packets to be sent to the CPU for processing and prevent the main control board from being overloaded by a large number of packets that are sent to the CPU. The source tracing protocol needs to apply for an independent CAR channel and has small CAR values configured.</p>

Typical Scenarios

Scenario where all nodes support source tracing

All nodes on the network support source tracing, and DeviceA is the faulty source. [Figure 1-89](#) shows the networking.

Figure 1-89 Scenario where all nodes support source tracing

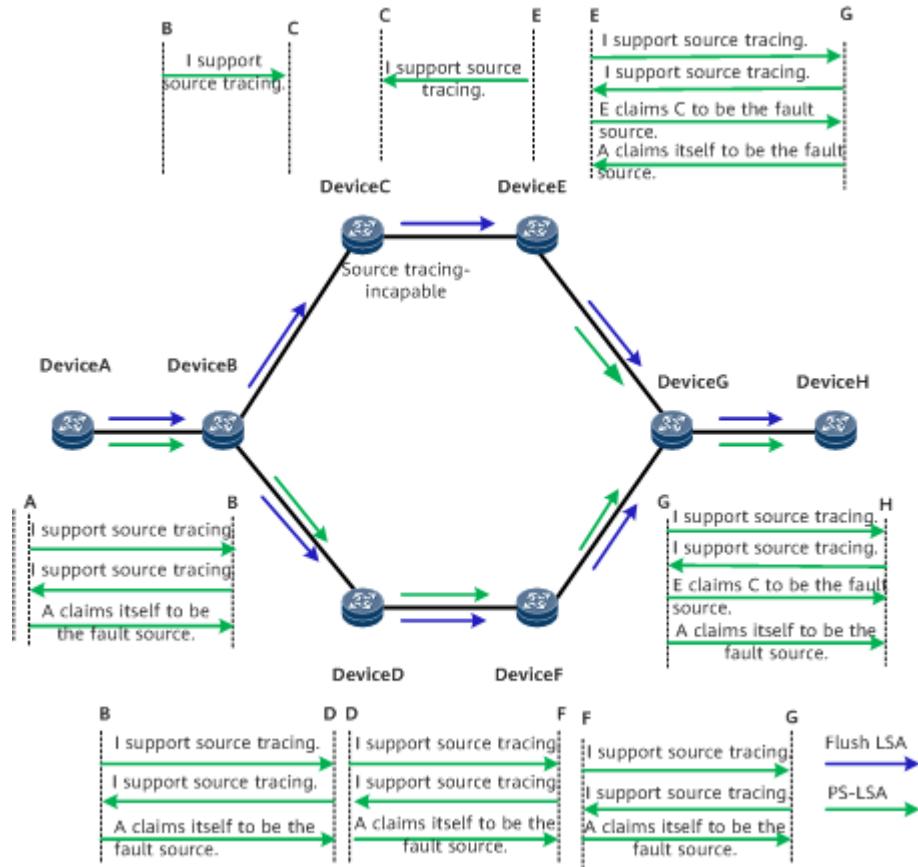

When DeviceA flushes an OSPF LSA, it generates a PS-LSA that carries DeviceA information and brief information about the flush LSA and floods it. After the fault occurs, maintenance personnel can log in to any node on the network to locate DeviceA, which keeps sending flush LSAs, and isolate DeviceA from the network.

Scenario where source tracing-incapable nodes are not isolated from source tracing-capable nodes

All nodes on the network except DeviceC support source tracing, and DeviceA is the fault source. In this case, the PS-LSA can be flooded on the entire network, and the fault source can be accurately located. [Figure 1-90](#) shows the networking.

Figure 1-90 Scenario where source tracing-incapable nodes are not isolated from source tracing-capable nodes

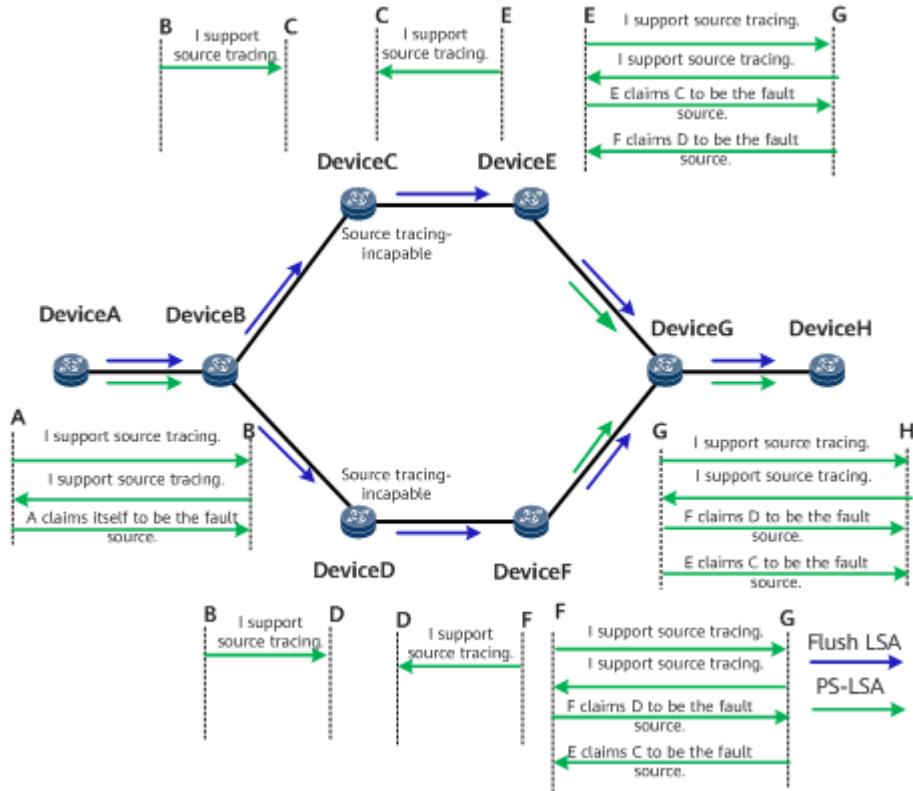

When DeviceA flushes an OSPF LSA, it generates a PS-LSA that carries DeviceA information and brief information about the flush LSA and floods it. When DeviceB and DeviceE negotiate the source tracing capability with DeviceC, they find that DeviceC does not support source tracing. Therefore, after DeviceB receives the PS-LSA from DeviceA, DeviceB sends the PS-LSA to DeviceD, but not to DeviceC. After receiving the flush LSA from DeviceC, DeviceE generates a PS-LSA that carries information about the advertisement source (DeviceE), flush source (DeviceC), and the OSPF flush LSA, and floods the PS-LSA on the network.

After the fault occurs, maintenance personnel can log in to any device on the network except DeviceC to locate the faulty node. Two possible faulty nodes can be located in this case: DeviceA and DeviceC, and they both send the same flush LSA. In this case, DeviceA takes precedence over DeviceC when the maintenance personnel determine the most possible faulty source. After DeviceA is isolated, the network recovers.

Scenario where source tracing-incapable nodes are isolated from source tracing-capable nodes

All nodes on the network except DeviceC and DeviceD support source tracing, and DeviceA is the fault source. In this case, the PS-LSA cannot be flooded on the entire network. [Figure 1-91](#) shows the networking.

Figure 1-91 Scenario where source tracing-incapable nodes are isolated from source tracing-capable nodes

When DeviceA flushes an OSPF LSA, it generates a PS-LSA that carries DeviceA information and brief information about the flush LSA and floods it. However, the PS-LSA sent by DeviceA can reach only DeviceB because DeviceC and DeviceD do not support source tracing.

During source tracing capability negotiation, DeviceE finds that DeviceC does not support source tracing, and DeviceF finds that DeviceD does not support source tracing. After DeviceE receives the flush LSA from DeviceC, DeviceE generates and floods a PS-LSA on behalf of DeviceC. Similarly, after DeviceF receives the flush LSA from DeviceD, DeviceF generates and floods a PS-LSA on behalf of DeviceD.

After the fault occurs:

- If maintenance personnel log in to DeviceA or DeviceB, the personnel can locate the fault source (DeviceA) directly. After DeviceA is isolated, the network recovers.
- If the maintenance personnel log in to DeviceE, DeviceF, DeviceG, or DeviceH, the personnel will find that DeviceE claims DeviceC to be the fault source of the OSPF flush LSA and DeviceF claims DeviceD to be the fault source of the same OSPF flush LSA.
- If the maintenance personnel log in to DeviceC and DeviceD, the personnel will find that the flush LSA was initiated by DeviceB, not generated by DeviceC or DeviceD.
- If the maintenance personnel log in to DeviceB, the personnel will find that DeviceA is the faulty device, and isolate DeviceA. After DeviceA is isolated, the network recovers.

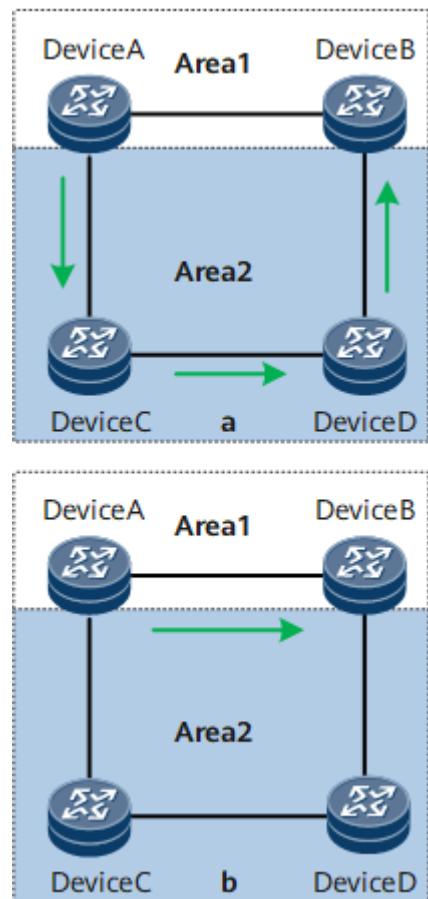

OSPF Multi-Area Adjacency

Context

OSPF prefers the shortest path during intra-area route calculation. Even if an inter-area path is the shortest, OSPF still prefers an intra-area route. Each OSPF interface belongs to only one area. As a result, even if a high-speed link exists in an area, traffic of another area cannot be forwarded along this link. The preceding problem can be solved by configuring multiple sub-interfaces and adding them to different areas. However, the disadvantage of this method is that multiple sub-interfaces need to be enabled and each sub-interface needs to be configured with an independent IP address. As a result, a large number of IP addresses are advertised, increasing the total number of routes. To address this issue, OSPF multi-area adjacency is introduced.

OSPF multi-area adjacency allows an OSPF interface to be added to multiple areas so that a link can be shared by these areas.

Figure 1-92 Traffic forwarding paths before and after OSPF multi-area adjacency is configured

On the network shown in [Figure 1-92](#), the link between DeviceA and DeviceB is a high-speed link in area 1.

Before OSPF multi-area adjacency is configured, traffic from DeviceA to DeviceB in area 2 is forwarded along a low-speed path (DeviceA -> DeviceC -> DeviceD -> DeviceB), as shown in [Figure 1-92 a](#).

After OSPF multi-area adjacency interfaces are configured on DeviceA and DeviceB and are added to area 2, traffic from DeviceA to DeviceB in area 2 is forwarded along the high-speed link (DeviceA -> DeviceB), as shown in [Figure 1-92 b](#).

This feature has the following advantages:

- Allows interface multiplexing, thereby reducing the consumption of OSPF interface resources in multi-area scenarios.
- Allows link multiplexing, which prevents a traffic detour to low-speed links and optimizes the OSPF network.

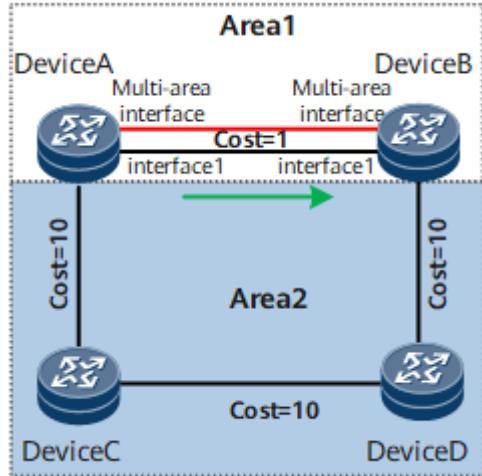

Related Concepts

Multi-area adjacency interface: OSPF logical interface created by enabling multi-area adjacency on an OSPF primary interface. A multi-area adjacency interface is also called a secondary interface. The multi-area adjacency interface has the following characteristics:

- The multi-area adjacency interface and the primary interface belong to different OSPF areas.
- The network type of the multi-area adjacency interface can only be P2P. The multi-area adjacency interface runs an independent interface state machine and neighbor state machine.
- The multi-area adjacency interface and primary interface share the same interface index and packet transmission channel. Whether the multi-area adjacency interface or the primary interface is selected to forward an OSPF packet is determined by the area ID carried in the packet header and related configuration.
- The multi-area adjacency interface of a P2P interface sends protocol packets in multicast mode.
- The multi-area adjacency interface of a non-P2P interface sends protocol packets in unicast mode.

Fundamentals

Figure 1-93 Networking for OSPF multi-area adjacency

On the network shown in [Figure 1-93](#), the link between DeviceA and DeviceB is a high-speed link in area 1. In area 2, traffic from DeviceA to DeviceB is forwarded along a low-speed path (DeviceA -> DeviceC -> DeviceD -> DeviceB), as shown in [Figure 1-93](#). To forward traffic from DeviceA to DeviceB in area 2 along the high-speed link DeviceA -> DeviceB, configure OSPF multi-area adjacency.

Specifically, create OSPF multi-area adjacency interfaces on the primary interfaces of DeviceA and DeviceB and add the multi-area adjacency interfaces to area 2.

1. An adjacency is established between the multi-area adjacency interfaces of DeviceA and DeviceB. The process of establishing such an adjacency is the same as that of establishing a common OSPF adjacency. For details, see [Adjacency Establishment](#).
2. OSPF performs route calculation. The calculation process is the same as that in the basic OSPF protocol. For details, see [Route Calculation](#).

The optimal path calculated by OSPF in area 2 is the path DeviceA -> DeviceB. Therefore, traffic from DeviceA to DeviceB is forwarded along the high-speed link DeviceA -> DeviceB. In this manner, this high-speed link can be shared by area 1 and area 2.

OSPF NSR

Non-Stop Routing (NSR) is a routing technique that prevents neighboring routers from detecting faults on the control plane of a device with a backup control plane. With NSR, when the control plane of the device fails, the neighbor relationship set up through specific routing protocols, MPLS, and other protocols that carry services is uninterrupted.

As networks develop and expand, carriers place increasingly higher requirements on the reliability of IP networks. NSR was introduced as a high availability (HA) solution to ensure that services transmitted by a device were unaffected by hardware or software failures on the device.

OSPF NSR synchronizes the protocol data on the master main control board to the slave main control board in real time. When the master main control board fails or

needs to be upgraded, the slave main control board immediately takes over services from the master main control board, and the neighbor remains unaware the fault occurred. Real-time data synchronization between the master and slave main control boards through OSPF NSR is implemented as follows:

- OSPF backs up configuration data and dynamic data, including information about interfaces, neighbors, and LSDBs.
- OSPF does not back up routes, shortest path trees (SPTs), or Traffic Engineering Databases (TEDBs). Such information can be restored using the source data in the database backup process.
- When the master/slave main control board switchover occurs, the new master main control board restores the operations data and takes over services from the former master main control board. Throughout this process, the neighbor remains unaware of the fault.

OSPF IP FRR

OSPF IP fast reroute (FRR) refers to the process by which OSPF precomputes a backup path based on the network-wide LSDBs, and stores this backup path in the forwarding table. If the primary path fails, traffic can be quickly switched to the backup path.

Context

As networks develop, voice over IP (VoIP) and online video services pose higher requirements for real-time transmission. Nevertheless, if a primary link fails, OSPF-enabled devices need to perform multiple operations, including detecting the fault, updating the link-state advertisement (LSA), flooding the LSA, calculating routes, and delivering forward information base (FIB) entries before switching traffic to a new link. This process takes a much longer time, the minimum delay to which users are sensitive. As a result, the requirements for real-time transmission cannot be met. OSPF IP FRR can solve this problem. OSPF IP FRR conforms to dynamic IP FRR defined by standard protocols. With OSPF IP FRR, devices can switch traffic from a faulty primary link to a backup link, protecting against a link or node failure.

Major FRR techniques include loop-free alternate (LFA), U-turn, Not-Via, Remote LFA, and MRT, among which OSPF supports only LFA and Remote LFA.

Related Concepts

OSPF IP FRR

OSPF IP FRR refers to a mechanism in which a device uses the loop-free alternate (LFA) algorithm to compute the next hop of a backup link and stores the next hop together with the primary link in the forwarding table. If the primary link fails, the device switches the traffic to the backup link before routes are converged on the control plane. This mechanism keeps the traffic interruption duration and minimizes the impacts.

OSPF IP FRR policy

An OSPF IP FRR policy can be configured to filter alternate next hops. Only the alternate next hops that match the filtering rules of the policy can be added to the IP routing table.

LFA algorithm

A device uses the shortest path first (SPF) algorithm to calculate the shortest path from each neighbor with a backup link to the destination node. The device then uses the inequalities defined in standard protocols and the LFA algorithm to calculate the next hop of the loop-free backup link that has the smallest cost of the available shortest paths.

Remote LFA

LFA FRR cannot be used to calculate alternate links on large-scale networks, especially on ring networks. Remote LFA FRR addresses this problem by calculating a PQ node and establishing a tunnel between the source node of a primary link and the PQ node. If the primary link fails, traffic can be automatically switched to the tunnel, which improves network reliability.

P space

Remote LFA uses the source end of the primary link as the root node and calculates an SPT to all the other nodes on the network (with the primary link calculated in the tree). After all the nodes along the primary link are removed from the SPT, the remaining nodes on the SPT form the P space.

Extended P space

Remote LFA uses all neighbors of the primary link's source end as root nodes and calculates separate SPTs (with the primary link calculated in the trees). After all the nodes along the primary link are removed from each SPT, the remaining nodes on the SPTs form the extended P space.

Q space

Remote LFA uses the destination node as the root node and calculates an SPT to all the other nodes on the network (with the primary link calculated in the tree). After all the nodes along the primary link are removed from the SPT, the remaining nodes on the SPT form the Q space.

PQ node

A PQ node exists both in the extended P space and Q space and is used by Remote LFA as the destination of a protection tunnel.

OSPF LFA FRR

OSPF LFA FRR protects traffic against either a link failure or a node-and-link failure. The node-and-link protection takes precedence over the link protection.

Link protection

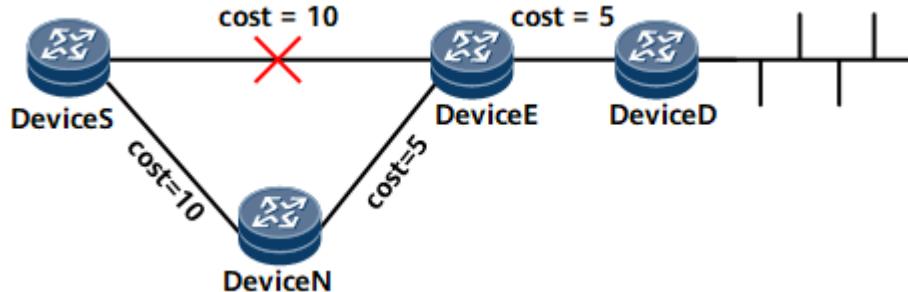

Link protection takes effect when the traffic to be protected flows along a specified link.

In [Figure 1-94](#), traffic flows from Device S to Device D. The primary link is Device S->Device E->Device D, and the backup link is Device S->Device N->Device E->Device D. If link costs meet the inequality: $\text{Distance}_{\text{opt}}(N, D) < \text{Distance}_{\text{opt}}(N, S) + \text{Distance}_{\text{opt}}(S, D)$ and OSPF IP FRR is enabled, Device S switches the traffic to the backup link if the primary link fails, reducing the traffic interruption duration.

 NOTE

Distance_opt(X, Y) indicates the shortest link from X to Y. S stands for a source node, E for the faulty node, N for a node along a backup link, and D for a destination node.

Figure 1-94 OSPF IP FRR link protection

Node-and-link protection

Node-and-link protection takes effect when the traffic to be protected.

In [Figure 1-95](#), traffic flows from Device S to Device D. The primary link is Device S->Device E->Device D, and the backup link is Device S->Device N->Device D. The preceding inequalities are met. With OSPF IP FRR, Device S switches the traffic to the backup link if the primary link fails, reducing the traffic interruption duration.

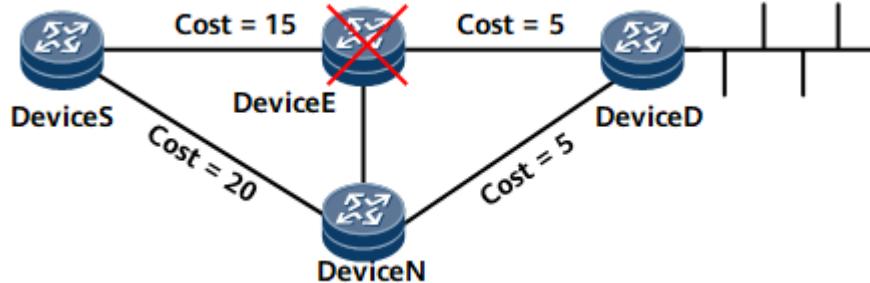

Node-and-link protection takes effect when the following conditions are met:

- The link costs meet the inequality: $\text{Distance}_{\text{opt}}(N, D) < \text{Distance}_{\text{opt}}(N, S) + \text{Distance}_{\text{opt}}(S, D)$.
- The interface costs meet the inequality: $\text{Distance}_{\text{opt}}(N, D) < \text{Distance}_{\text{opt}}(N, E) + \text{Distance}_{\text{opt}}(E, D)$.

 NOTE

Distance_opt(X, Y) indicates the shortest link from X to Y. S stands for a source node, E for the faulty node, N for a node along a backup link, and D for a destination node.

Figure 1-95 OSPF IP FRR node-and-link protection

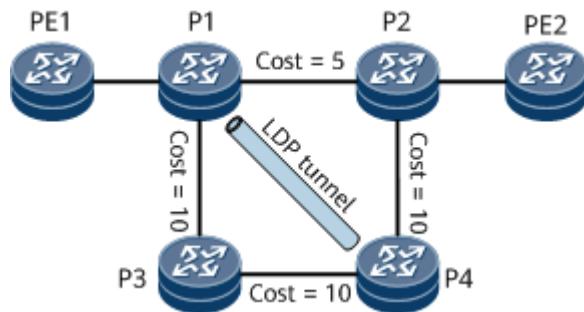

OSPF Remote LFA FRR

Similar to OSPF LFA FRR, remote LFA is also classified as link protection or node-and-link protection. The following example shows how remote LFA works to protect against link failures:

In [Figure 1-96](#), traffic flows through PE1 -> P1 -> P2 -> PE2, and the primary link is between P1 and P2. Remote LFA calculates a PQ node (P4) and establishes an LDP between P1 and P4. If P1 detects a failure on the primary link, P1 encapsulates packets into MPLS packets and forwards MPLS packets to P4. After receiving the packets, P4 removes the MPLS label from them and searches the IP routing table for a next hop to forward the packets to PE2. Remote LFA ensures uninterrupted traffic forwarding.

Figure 1-96 Networking for Remote LFA

On the network shown in [Figure 1-96](#), Remote LFA calculates the PQ node as follows:

1. SPTs are calculated, with each of P1's neighbors (excluding the neighbors on the primary link) as the root. In this case, the neighbors PE1 and P3 are used as roots. For each SPT, an extended P space is composed of the root node and those nodes reachable through non-P1-P2 links. When PE1 is used as a root node for calculation, the extended P space {PE1, P1, P3} is obtained. When P3 is used as a root node for calculation, the extended P space {PE1, P1, P3, P4} is obtained. By combining these two extended P spaces, the final extended P space {PE1, P1, P3, P4} is obtained.
2. A reverse SPT with PE2 as the root is calculated. The Q space is {P2, PE2, P4}.
3. The node that exists both in the extended P space and Q space is the PQ node. In this example, P4 is the PQ node.

NOTE

On a network with a large number of nodes, to ensure that RLFA/TI-LFA calculation can be completed as soon as possible, the elected P and Q nodes may not be optimal, but they comply with rules. This does not affect the protection effect.

OSPF microloop avoidance

In [Figure 1-96](#), OSPF remote LFA FRR is enabled, the primary link is PE1 -> P1 -> P2 -> PE2, and the backup link is PE1 -> P1 -> P3 -> P4 -> P2 -> PE2, and the link P1 -> P3 -> P4 is an LDP tunnel. If the primary link fails, traffic is switched to the backup link, and then another round of the new primary link calculation begins. Specifically, after P1 completes route convergence, its next hop becomes P3. However, the route convergence on P3 is slower than that on P1, and P3's next

hop is still P1. As a result, a temporary loop occurs between P1 and P3. OSPF microloop avoidance can address this problem by delaying P1 from switching its next hop until the next hop of P3 becomes P4. Then traffic is switched to the new primary link (PE1 -> P1 -> P3 -> P4 -> P2 -> PE2), and on the link P1 -> P3 -> P4, traffic is forwarded based on IP routes.

 NOTE

OSPF microloop avoidance applies only to OSPF remote LFA FRR.

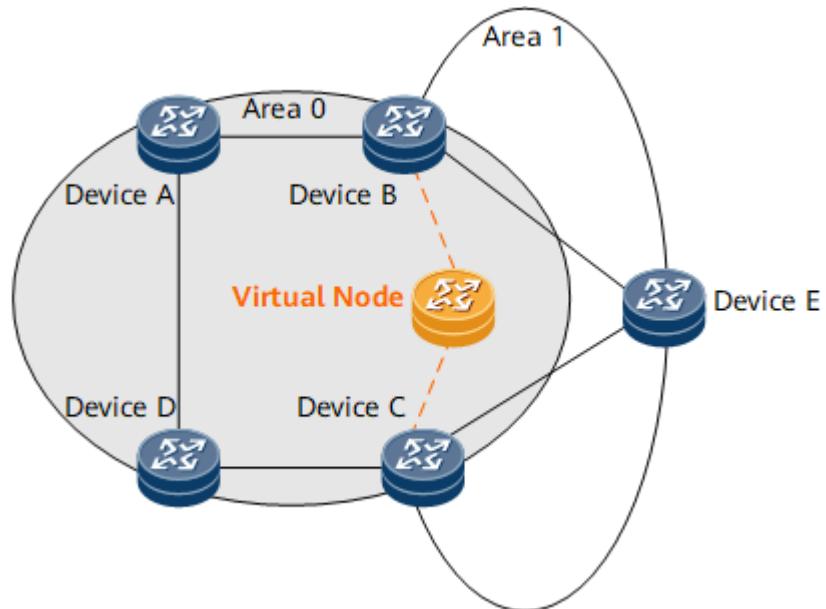

OSPF FRR in the Scenario Where Multiple Nodes Advertise the Same Route

The SPF algorithm is used by OSPF LFA FRR and OSPF Remote LFA FRR to calculate the shortest path from each neighbor (root node) that provides a backup link to the destination node. The calculation result is a node-based backup next hop. This applies to the scenarios where a route is advertised by a single node. As networks are increasingly diversified, two ABRs or ASBRs are deployed to improve network reliability. In this case, OSPF FRR in a scenario where multiple nodes advertise the same route is introduced.

 NOTE

In a scenario where multiple nodes advertise the same route, OSPF FRR is implemented by calculating the Type 3 LSAs advertised by ABRs of an area for intra-area, inter-area, ASE, or NSSA routes. Therefore, the OSPF FRR calculation methods are the same when multiple nodes advertise the same route. Inter-area routing is used as an example to describe how FRR in a multi-node routing scenario works.

Figure 1-97 OSPF FRR in the scenario where multiple nodes advertise the same route

In **Figure 1-97**, Device B and Device C function as ABRs to forward routes between area 0 and area 1. Device E advertises an intra-area route. Upon receipt of the route, Device B and Device C translate it into a Type 3 LSA and flood the LSA to area 0. After OSPF FRR is enabled on Device A, Device A considers both Device B and Device C as its neighbors. Without a fixed neighbor as the root node, Device A

fails to calculate the FRR backup next hop. To address this problem, a virtual node is simulated between Device B and Device C, converting the scenario where multiple nodes advertise the same route into the scenario where the route is received from only one node. Then the backup next hop of the virtual node is calculated based on LFA and Remote LFA. Then the route advertised by multiple nodes inherits the backup next hop from the virtual node.

For example, Device B and Device C advertise a route with prefix 10.1.1.0/24, and OSPF FRR is enabled on Device A. Device A cannot calculate a backup next hop for the route 10.1.1.0/24 because this route has two sources (Device B and Device C). To address this problem, a virtual node is simulated between Device B and Device C based on the two sources of the route 10.1.1.0/24. The virtual node forms a link with each of Device B and Device C. If the virtual node advertises a 10.1.1.0/24 route, it will use the smaller cost of the routes advertised by Device B and Device C as the cost of the route. If the cost of the route advertised by Device B is 5 and that of the route advertised by Device C is 10, the cost of the route advertised by the virtual node is 5. The cost of the link from Device B to the virtual node is 0, and that of the link from Device C to the virtual node is 5. The costs of the links from the virtual node to Device B and Device C are both 65535, the maximum value. Device A is configured to consider Device B and Device C as invalid sources of the 10.1.1.0/24 route and use the LFA or remote LFA algorithm to calculate the backup next hop for the route, with the virtual node as the root node.

In a scenario where multiple nodes advertise the same route, OSPF FRR can use the LFA or remote LFA algorithm. When OSPF FRR uses the remote LFA algorithm, PQ node selection has the following restrictions:

- An LDP tunnel will be established between a faulty node and a PQ node, and a virtual node in the scenario where multiple nodes advertise the same route cannot transmit traffic through LDP tunnels. As a result, the virtual node cannot be selected as a PQ node.
- The destination node of Remote LFA is not selected as a PQ node. After a virtual node is added in a scenario where multiple nodes advertise the same route, the destination node becomes a virtual node. Therefore, a node directly connected to the virtual node cannot be selected as a PQ node.

OSPF SRLG FRR

A shared risk link group (SRLG) is a set of links that share a common physical resource (such as a fiber). These links share the same risk level. If one of the links fails, all the other links in the SRLG may also fail.

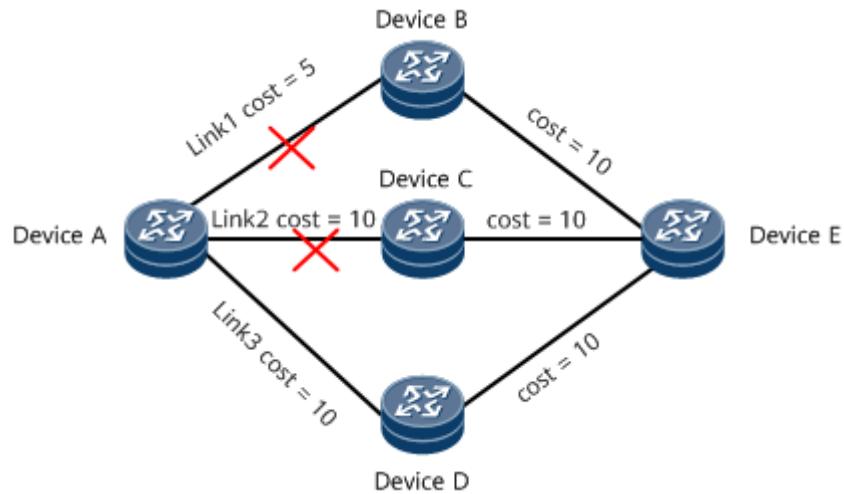

On the network shown in [Figure 1-98](#), traffic is forwarded from Device A to Device E. There are three links between Device A and Device E: Link1, Link2, and Link3. The cost of Link1 is the smallest, and the costs of Link2 and Link3 are the same. Therefore, Link1 is the primary link for traffic forwarding.

OSPF LFA IP FRR provides protection for Link1, and Link2 or Link3 is selected as the backup link for traffic forwarding. Assume that Link2 is selected as the backup link:

- If link 1 fails but the backup link (link 2) is normal, traffic can be forwarded normally after being switched to the backup link.
- If both link 1 and link 2 fail, traffic is interrupted after being switched to the backup link.

OSPF SRLG FRR can be configured in the scenario where some links have the same risk of failure. If Link1 and Link2 have the same risk of failure, you can add them to an SRLG and configure OSPF SRLG FRR so that a link outside the SRLG is preferentially selected as a backup link, which reduces the possibility of service interruptions. After Link1 and Link2 are added to the same SRLG, OSPF LFA IP FRR selects Link3, which is not in the SRLG, as the backup link to provide protection for Link1. If both Link1 and Link2 fail, traffic can be switched to Link3 for normal transmission.

Figure 1-98 Networking diagram of OSPF SRLG FRR

Derivative Functions

If you bind a Bidirectional Forwarding Detection (BFD) session with OSPF IP FRR, the BFD session goes down if BFD detects a link fault. If the BFD session goes down, OSPF IP FRR is triggered to switch traffic from the faulty link to the backup link, which minimizes the loss of traffic.

OSPF Authentication

OSPF authentication encrypts OSPF packets by adding the authentication field to packets to ensure network security. When receiving an OSPF packet from a remote device, the local device discards the packet if the authentication password carried in the packet is different from the local one, protecting the local device against potential attacks.

In terms of the packet type, the authentication is classified as follows:

- Area authentication: configured in the OSPF area view and applies to packets on all interfaces in the OSPF area.
- Interface authentication: configured in the interface view and applies to all packets on the interface.

In terms of packet the authentication modes, the authentication is classified as follows:

- Non-authentication: Authentication is not performed.
- Simple authentication: A configured password is directly added to packets for authentication. This authentication mode is insecure.

- Message-digest algorithm 5 (MD5) authentication: A configured password is hashed using an algorithm such as MD5, and the ciphertext password is added to packets for authentication. This authentication mode improves password security. Currently, MD5 and hash-based message authentication code for MD5 (HMAC-MD5) are supported. For the sake of security, using the HMAC-SHA256 algorithm rather than the MD5 algorithm is recommended.
- Keychain authentication: A keychain consists of multiple authentication keys, each of which contains an ID and a password. Each key in a keychain has a lifecycle, based on which keys are dynamically selected. A keychain can also dynamically select an authentication key to enhance attack defense.
Keychain improves OSPF security by dynamically changing algorithms and keys. Keychain authentication can be used to authenticate OSPF packets and the process of establishing a TCP connection as well.
- HMAC-SHA256 authentication: A configured password is hashed using the HMAC for secure hash algorithm 256 (HMAC-SHA256) algorithm, and the ciphertext password is added to packets for authentication. This authentication mode improves password security.

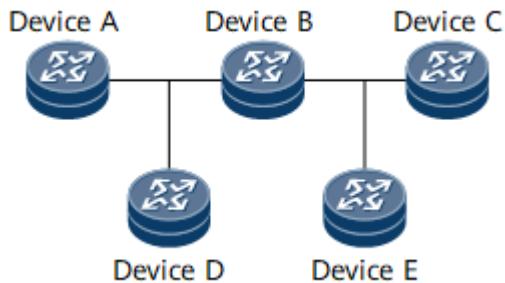

OSPF carries authentication types in packet headers and authentication information in packet tails.

The authentication types include:

- 0: non-authentication
- 1: simple authentication
- 2: Ciphertext authentication

Usage Scenario

Figure 1-99 OSPF authentication on a broadcast network

The configuration requirements are as follows:

- The interface authentication configurations must be the same on all devices on the same network so that OSPF neighbor relationships can be established.
- The area authentication configurations must be the same on all devices in the same area.

OSPF Packet Format

The OSPF protocol number is 89. OSPF packets are encapsulated into IP packets. OSPF packets are classified into five types of packets: Hello packets, DD packets, LSR packets, LSU packets, and LSAck packets.

- [Hello packet](#)
- [DD packet](#)
- [LSR packet](#)
- [LSU packet](#)
- [LSAck packet](#)

Packet Header Format

The five types of OSPF packets have the same packet header format. The length of an OSPF packet header is 24 bytes. [Figure 1-100](#) shows an OSPF packet header.

Figure 1-100 Packet header format

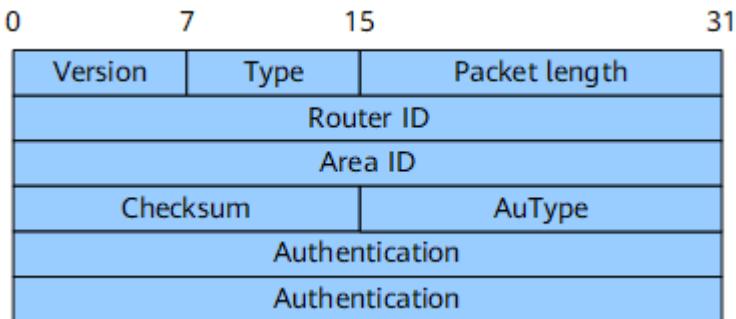

Table 1-33 OSPF packet header fields

Field	Length	Description
Version	8 bits	OSPF version number. For OSPFv2, the value is 2.
Type	8 bits	OSPF packet type. The values are as follows: <ul style="list-style-type: none">● 1: Hello packet● 2: DD packet● 3: LSR packet● 4: LSU packet● 5: LSAck packet
Packet length	16 bits	Length of the OSPF packet with the packet header, in bytes.
Router ID	32 bits	ID of the router that sends the OSPF packet.
Area ID	32 bits	ID of the area to which the router that sends the OSPF packet belongs.
Checksum	16 bits	Checksum of the OSPF packet that does not carry the Authentication field.

Field	Length	Description
AuType	16 bits	<p>Authentication type. The values are as follows:</p> <ul style="list-style-type: none">• 0: non-authentication• 1: simple authentication• 2: message digest algorithm 5 (MD5) authentication <p>NOTE The MD5 algorithm is insecure and poses security risks.</p>
Authentication	64 bits	This field has different meanings for different AuType values: <ul style="list-style-type: none">• 0: This field is not defined.• 1: This field defines password information.• 2: This field contains the key ID, MD5 authentication data length, and sequence number.

 **NOTE**

MD5 authentication data is added to an OSPF packet and is not included in the Authentication field.

Hello Packet

Hello packets are commonly used packets, which are periodically sent by OSPF interfaces to establish and maintain neighbor relationships. A Hello packet includes information about the designated router (DR), backup designated router (BDR), timers, and known neighbors. [Figure 1-101](#) shows the format of a Hello packet.

Figure 1-101 Format of a Hello packet

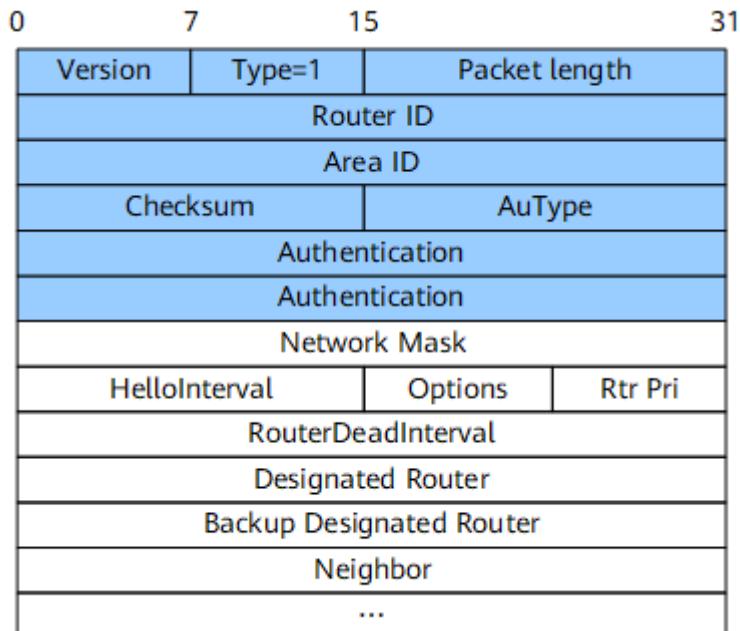

Table 1-34 Hello packet fields

Field	Length	Description
Network Mask	32 bits	Mask of the network on which the interface that sends the Hello packet resides.
HelloInterval	16 bits	Interval at which Hello packets are sent.
Options	8 bits	The values are as follows: <ul style="list-style-type: none"> • E: AS-external-LSAs can be flooded. • MC: IP multicast packets are forwarded. • N/P: Type 7 LSAs are processed. • DC: On-demand links are processed.
Rtr Pri	8 bits	DR priority. The default value is 1. NOTE If the DR priority of a router interface is set to 0, the interface cannot participate in a DR or BDR election.
RouterDeadInterval	32 bits	Dead interval. If a device does not receive any Hello packets from its neighbors within a specified dead interval, the neighbors are considered down.
Designated Router	32 bits	Interface address of the DR.
Backup Designated Router	32 bits	Interface address of the BDR.
Neighbor	32 bits	Router ID of the neighbor.

Table 1-35 lists the address types, interval types, and default intervals used when Hello packets are transmitted on different networks.

Table 1-35 Hello packet characteristics for various network types

Network Type	Address Type	Interval Type	Default Interval
Broadcast	Multicast address	HelloInterval	10 seconds
NBMA	Unicast address	<ul style="list-style-type: none"> • HelloInterval is used by the DR, BDR, and router that can become a DR. • PollInterval is used when neighbors become Down, and HelloInterval is used in other cases. 	30 seconds for HelloInterval 120 seconds for PollInterval

Network Type	Address Type	Interval Type	Default Interval
P2P	Multicast address	HelloInterval	10 seconds
P2MP	Multicast address	HelloInterval	30 seconds

NOTE

Routers on the same network segment must have the same HelloInterval and RouterDeadInterval values. Otherwise, they cannot establish neighbor relationships. In addition, on an NBMA network, the PollInterval values must be the same at both ends.

DD Packet

During an adjacency initialization, two routers use DD packets to describe their own link state databases (LSDBs) for LSDB synchronization. A DD packet contains the header of each LSA in an LSDB. An LSA header uniquely identifies an LSA. The LSA header occupies only a small portion of the LSA, which reduces the amount of traffic transmitted between routers. A neighbor can use the LSA header to check whether it already has the LSA. When two routers exchange DD packets, one functions as the master, and the other functions as the slave. The master defines a start sequence number and increases the sequence number by one each time it sends a DD packet. After the slave receives a DD packet, it uses the sequence number carried in the DD packet for acknowledgment.

[Figure 1-102](#) shows the format of a DD packet.

[Figure 1-102](#) Format of a DD packet

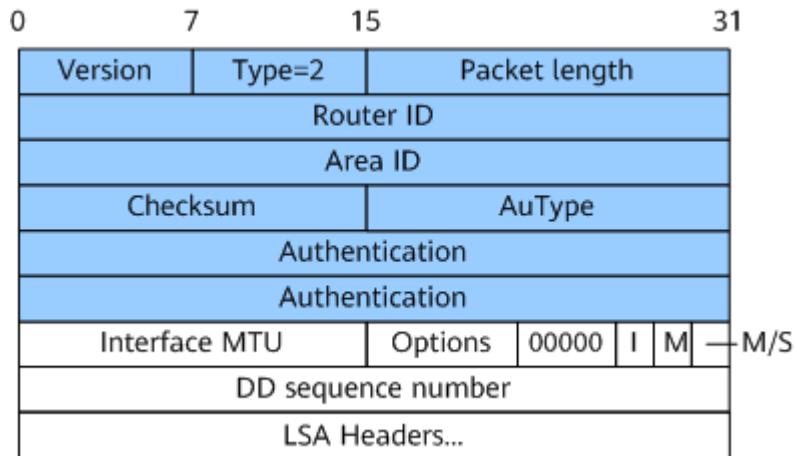

Table 1-36 DD packet fields

Field	Length	Description
Interface MTU	16 bits	Maximum size of an IP packet that an interface can send without fragmenting the packet.
Options	8 bits	The values are as follows: <ul style="list-style-type: none">• E: AS-external-LSAs can be flooded.• MC: IP multicast packets are forwarded.• N/P: Type 7 LSAs are processed.• DC: On-demand links are processed.
I	1 bit	If the DD packet is the first among multiple consecutive DD packets sent by a device, this field is set to 1. Otherwise, this field is set to 0.
M (More)	1 bit	If the DD packet is the last among multiple consecutive DD packets sent by a device, this field is set to 0. Otherwise, this field is set to 1.
M/S (Master/Slave)	1 bit	When two OSPF devices exchange DD packets, they negotiate a master/slave relationship. The device with a larger router ID becomes the master. If this field is set to 1, the device that sends the DD packet is the master.
DD sequence number	32 bits	Sequence number of the DD packet. The master and slave use the sequence number to ensure that DD packets are correctly transmitted.
LSA Headers	-	LSA header information included in the DD packet.

LSR Packet

After two routers exchange DD packets, they send LSR packets to request LSAs from each other. The LSR packets contain the summaries of the requested LSAs. [Figure 1-103](#) shows the format of an LSR packet.

Figure 1-103 Format of an LSR packet

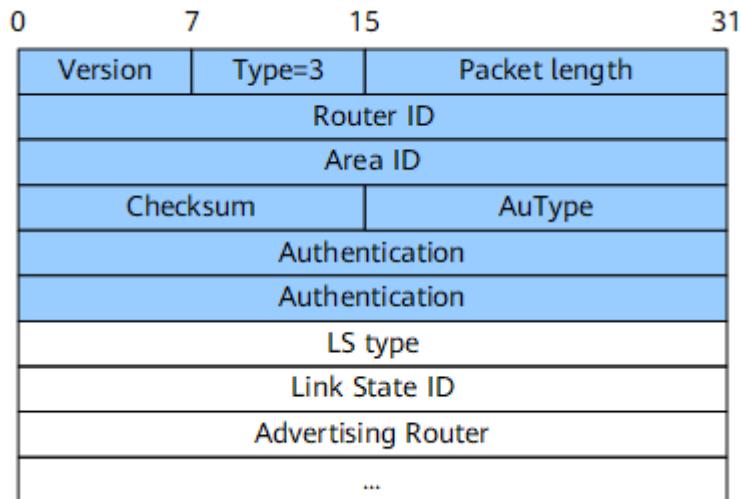

Table 1-37 LSR packet fields

Field	Length	Description
LS type	32 bits	Type of the LSA.
Link State ID	32 bits	This field together with the LS type field describes an LSA in an AS.
Advertising Router	32 bits	Router ID of the router that generates the LSA.

NOTE

The LS type, Link State ID, and Advertising Router fields can uniquely identify an LSA. If the preceding fields of two LSAs are the same, the device uses the LS sequence number, LS checksum, and LS age fields to determine which LSA is newer.

LSU Packet

A router uses an LSU packet to transmit LSAs requested by its neighbors or to flood its own updated LSAs. The LSU packet contains a set of LSAs. On networks that support multicast and broadcast, LSU packets are multicast to flood LSAs. To ensure reliable LSA flooding, a device uses an LSAck packet to acknowledge the LSAs contained in an LSU packet that is received from a neighbor. If an LSA fails to be acknowledged, the LSA is directly retransmitted to the neighbor. [Figure 1-104](#) shows the format of an LSU packet.

Figure 1-104 Format of an LSU packet

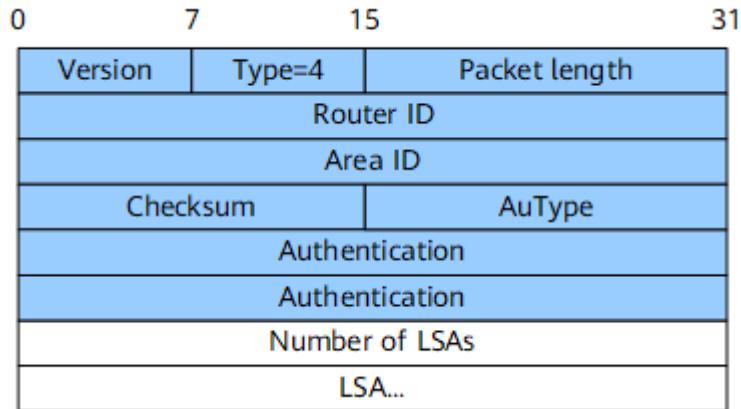

Table 1-38 LSU packet field

Field	Length	Description
Number of LSAs	32 bits	Number of LSAs contained in the LSU packet

LSAck Packet

A device uses an LSAck packet to acknowledge the headers of the LSAs contained in a received LSU packet. LSAck packets are transmitted in unicast or multicast mode according to the link type. [Figure 1-105](#) shows the format of an LSAck packet.

Figure 1-105 Format of an LSAck packet

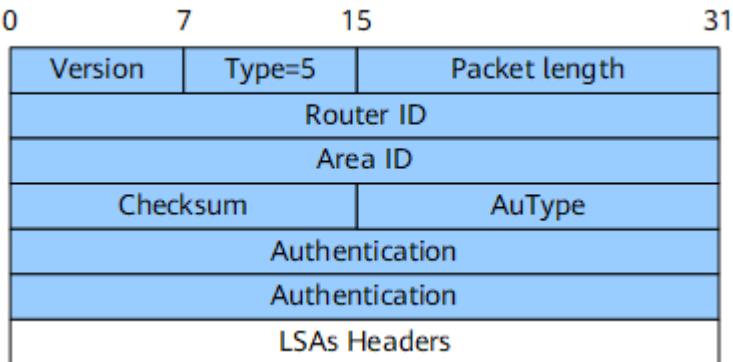

Table 1-39 LSAck packet field

Field	Length	Description
LSAs Headers	Determined by the header length of the LSA to be acknowledged.	This field is used to acknowledge an LSA.

OSPF LSA Format

Each router in an AS generates one or more types of LSAs based on its router type. A set of LSAs forms a link state database (LSDB). In OSPF, routing information is encapsulated in LSAs for advertisement. Common LSAs are as follows:

- **Router-LSAs**
- **Network-LSAs**
- **Summary-LSAs** (including Network-Summary-LSAs and ASBR-Summary-LSAs)
- **AS-External-LSAs**

LSA Header Information

All LSAs have the same header format, as shown in [Figure 1-106](#).

Figure 1-106 LSA header format

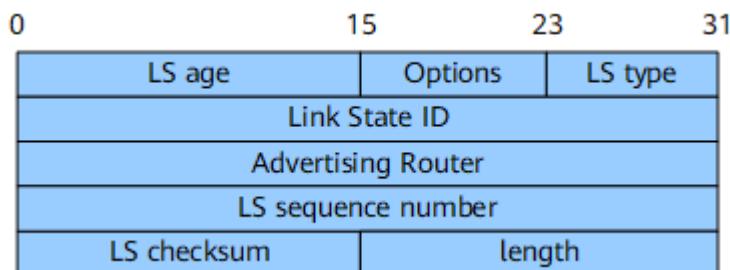

Table 1-40 LSA header fields

Field	Length	Description
LS age	16 bits	Time that has elapsed since an LSA is generated, in seconds. The value of this field continually increases regardless of whether the LSA is transmitted over a link or saved in an LSDB.

Field	Length	Description
Options	8 bits	<p>Available options:</p> <ul style="list-style-type: none"> • E: AS-External-LSAs can be flooded. • MC: IP multicast packets are forwarded. • N/P: Type 7 LSAs are processed. • DC: Demand circuits are processed. • DN: It prevents loops on an MPLS VPN. When a PE sends Type 3, Type 5, or Type 7 LSAs to a CE, the DN bit needs to be set. When other PEs receive the LSAs from the CE, they cannot use these LSAs for OSPF route calculation. • O: It indicates whether the originating router supports Opaque LSAs (Type 9, Type 10, and Type 11).
LS type	8 bits	<p>LSA type:</p> <ul style="list-style-type: none"> • Type 1: Router-LSA • Type 2: Network-LSA • Type 3: Network-Summary-LSA • Type 4: ASBR-Summary-LSA • Type 5: AS-External-LSA • Type 7: NSSA-LSA
Link State ID	32 bits	This field, together with the LS type field, uniquely identifies an LSA in a routing domain.
Advertising Router	32 bits	Router ID of the router that generates the LSA.
LS sequence number	32 bits	Sequence number of the LSA. Other routers can determine which LSA is the latest according to this value.
LS checksum	16 bits	Checksum of all fields except the LS age field.
length	16 bits	Length of the LSA including the LSA header, in bytes.

Router-LSA

Router-LSA (Type 1): describes the link states and cost of a router. It is generated by each router and advertised in the area to which the router belongs. [Figure 1-107](#) shows the Router-LSA format.

Figure 1-107 Router-LSA format

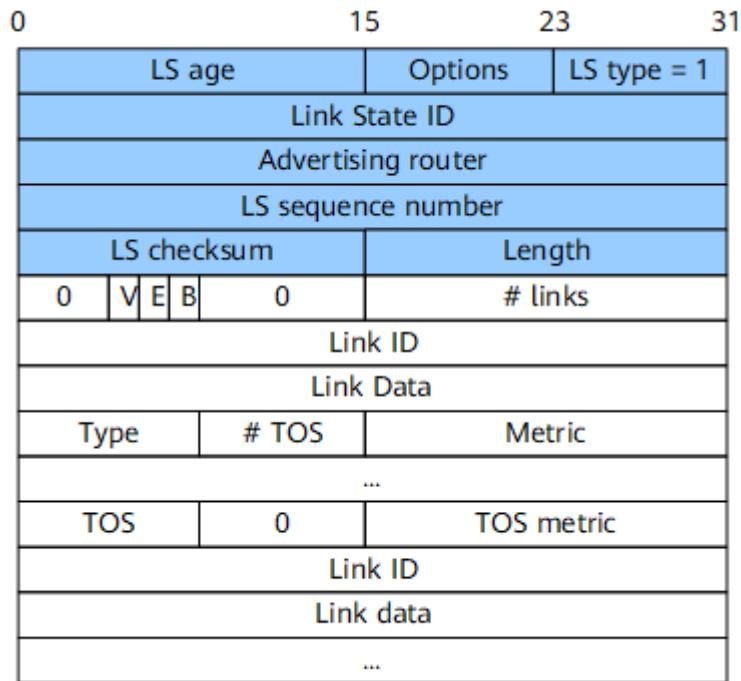

Table 1-41 Router-LSA fields

Field	Length	Description
Link State ID	32 bits	Router ID of the device that generates the LSA.
V (virtual link)	1 bit	If the router that generates the LSA is an endpoint of a virtual link, this field is set to 1. In other cases, this field is set to 0.
E (external)	1 bit	If the router that generates the LSA is an AS boundary router (ASBR), this field is set to 1. In other cases, this field is set to 0.
B (border)	1 bit	If the router that generates the LSA is an area border router (ABR), this field is set to 1. In other cases, this field is set to 0.
# links	16 bits	Number of links and interfaces described in the LSA, including all links and interfaces in the area to which the router belongs.
Link ID	32 bits	Object to which the router is connected. The value depends on the connection type. <ul style="list-style-type: none"> ● 1: router ID ● 2: interface IP address of the DR ● 3: network segment or subnet number ● 4: router ID of the neighbor on a virtual link

Field	Length	Description
Link Data	32 bits	Link data. The value varies according to the link type: <ul style="list-style-type: none"> • Unnumbered P2P: interface index • Stub network: subnet mask • Other connections: IP address of the router interface
Type	8 bits	Basic description of the router connection: <ul style="list-style-type: none"> • 1: connected to another router in P2P mode • 2: connected to a transit network • 3: connected to a stub network • 4: virtual link
# ToS	8 bits	Type of service (ToS) count.
metric	16 bits	Link cost.
ToS	8 bits	Type of service.
ToS metric	16 bits	Metric for the specified ToS.

Network-LSA

Network-LSA (Type 2): is generated by the DR on a broadcast or non-broadcast multiple access (NBMA) network. A Network-LSA records the router IDs of all routers on the network and describes the link states of all routers on the local network segment. It is advertised within the area to which the DR belongs. [Figure 1-108](#) shows the Network-LSA format.

Figure 1-108 Network-LSA format

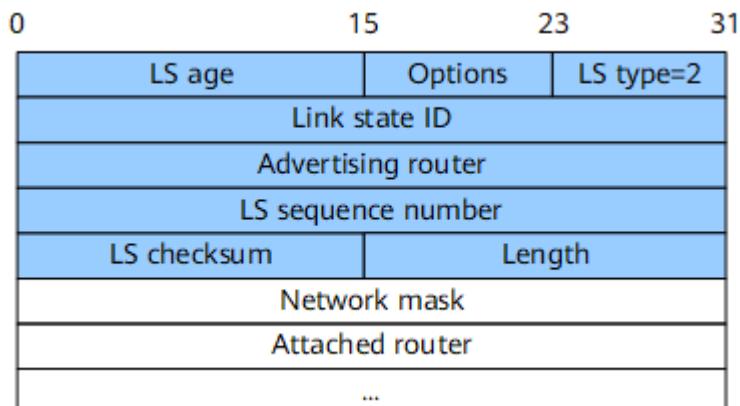

Table 1-42 Network-LSA fields

Field	Length	Description
Link State ID	32 bits	Interface IP address of the DR
Network Mask	32 bits	Mask of the broadcast or NBMA network
Attached Router	32 bits	Router IDs of all routers connected to the same network, including the router ID of the DR.

Summary-LSA

Network-Summary-LSA (Type 3): describes routes on a network segment in an area and is advertised to other related areas.

ASBR-Summary-LSA (Type 4): describes routes to an ASBR and is advertised to all related areas except the area to which the ASBR belongs.

Type 3 and Type 4 LSAs have the same format and are generated by ABRs. [Figure 1-109](#) shows the Summary-LSA format.

Figure 1-109 Summary-LSA format

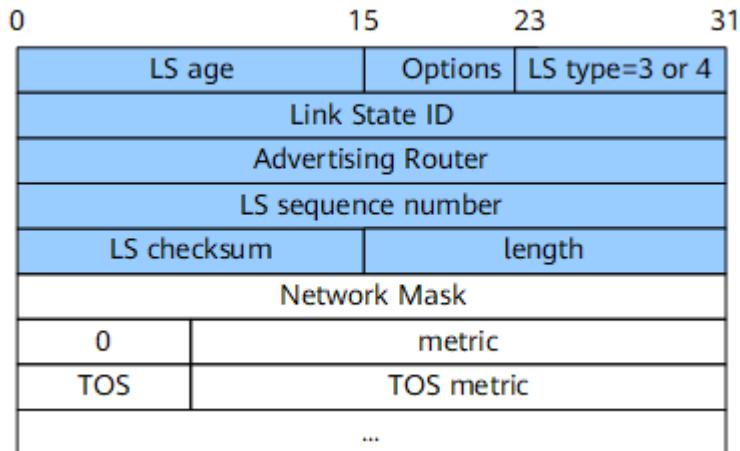

Table 1-43 Network-Summary-LSA fields

Field	Length	Description
Link State ID	32 bits	Advertised network address.
Network Mask	32 bits	Mask of the broadcast or NBMA network
metric	24 bits	Cost of the route to the destination address.
ToS	8 bits	Type of service.

Field	Length	Description
ToS metric	24 bits	Metric for the specified ToS.

 NOTE

When default routes are advertised, both the Link State ID and Network Mask fields are set to 0.0.0.0.

Table 1-44 ASBR-Summary-LSA fields

Field	Length	Description
Link State ID	32 bits	Router ID of the ASBR.
Network Mask	32 bits	This field is meaningless and is set to 0.0.0.0.
metric	24 bits	Cost of the route to the destination address.
ToS	8 bits	Type of service.
ToS metric	24 bits	Metric for the specified ToS.

AS-External-LSA

An AS-External-LSA (Type 5) describes AS external routes. AS-External-LSAs are generated by an ASBR. Among the five types of LSAs, only AS-External-LSAs can be advertised to all areas except stub areas and not-so-stubby areas (NSSAs).

[Figure 1-110](#) shows the AS-External-LSA format.

[Figure 1-110](#) AS-External-LSA format

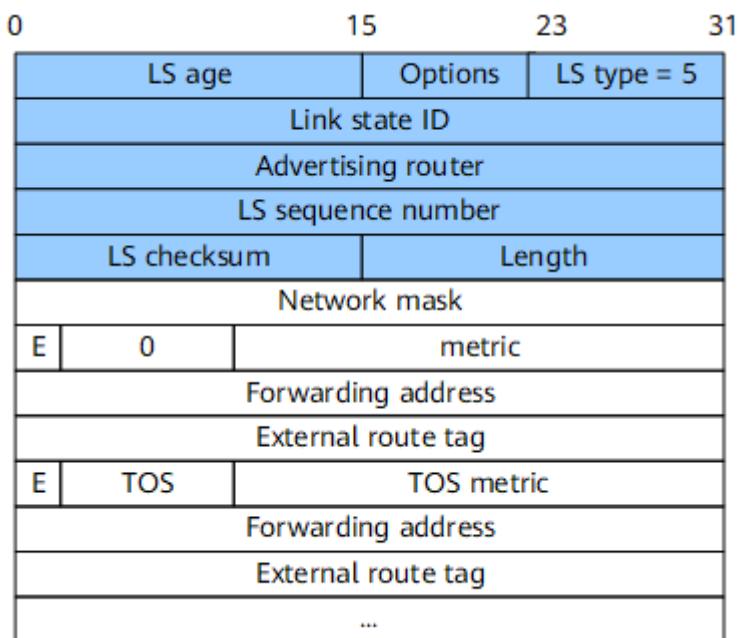

Table 1-45 AS-External-LSA fields

Field	Length	Description
Link State ID	32 bits	Advertised network address.
Network Mask	32 bits	Mask of the advertised destination address.
E	1 bit	Type of the external route. The values are as follows: <ul style="list-style-type: none">• 0: Type 1 external route• 1: Type 2 external route
metric	24 bits	Cost of the route to the destination address.
Forwarding Address	32 bits	Packets destined for the advertised destination address are forwarded to the address specified by this field.
External Route Tag	32 bits	Tag added to the external route. This field is not used by the OSPF protocol itself. It can be used to manage external routes.
ToS	8 bits	Type of service.
ToS metric	24 bits	Metric for the specified ToS.

 **NOTE**

If Type 5 LSAs are used to advertise default routes, both the Link State ID and Network Mask fields are set to 0.0.0.0.

Routing Loop Detection for Routes Imported to OSPF

Routes of an OSPF process can be imported to another OSPF process or the process of another protocol (such as IS-IS or BGP) for redistribution. However, if a device that performs such a route import is incorrectly configured, routing loops may occur. OSPF can use the routing loop detection function to detect routing loops.

Related Concepts

Redistribute ID

IS-IS uses a system ID as a redistribution identifier, OSPF and OSPFv3 use a router ID + process ID as a redistribution identifier, and BGP uses a VrfID + random number as a redistribution identifier. For ease of understanding, the redistribution identifiers of different protocols are all called Redistribute IDs. When routes are distributed, the information carried in the routes contains Redistribute IDs.

Redistribute List

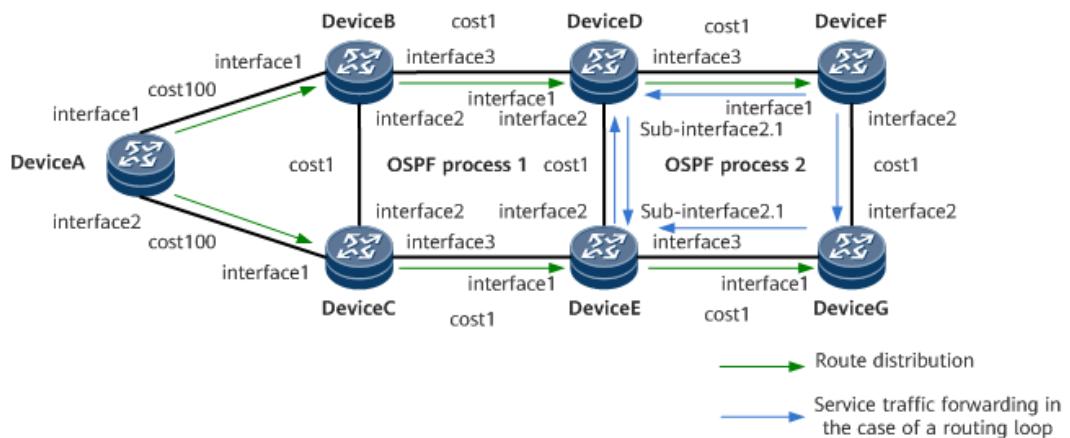

A Redistribute list may consist of multiple Redistribute IDs. Each Redistribute list of BGP contains a maximum of four Redistribute IDs, and each Redistribute list of

any other routing protocol contains a maximum of two Redistribute IDs. When the number of Redistribute IDs exceeds the corresponding limit, the old ones are discarded according to the sequence in which Redistribute IDs are added.

Cause (OSPF Inter-Process Mutual Route Import)

In [Figure 1-111](#), DeviceA, DeviceB, and DeviceC run OSPF process 1; DeviceF and DeviceG run OSPF process 2; DeviceD and DeviceE run both of the processes. Route import between OSPF process 1 and OSPF process 2 is configured on DeviceD and DeviceE. DeviceE imports routes from OSPF process 1 to OSPF process 2 for distribution. DeviceD imports the routes from OSPF process 2 to OSPF process 1 so that the routes are re-distributed back to OSPF process 1. As the costs of the routes newly distributed by DeviceD are smaller, they are preferentially selected by OSPF process 1, resulting in routing loops.

Figure 1-111 Typical network diagram of OSPF inter-process mutual route import

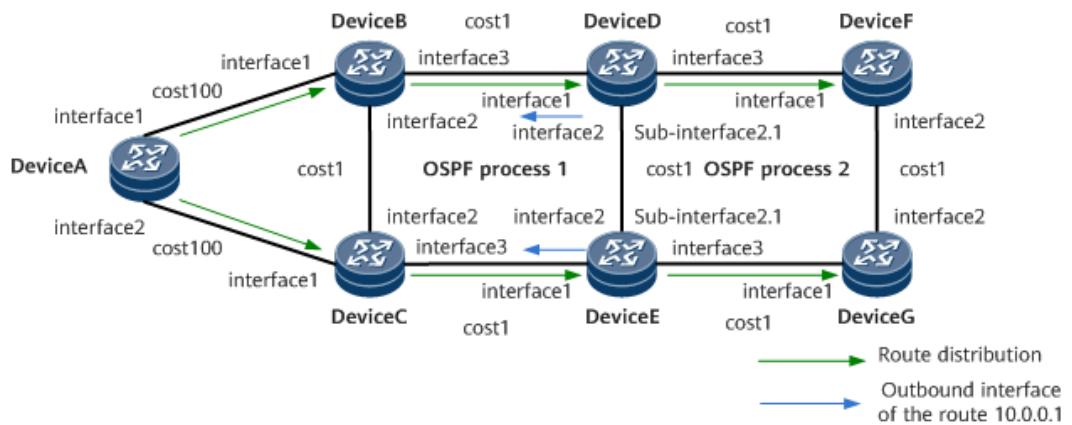

Take the route distributed by DeviceA as an example. A stable routing loop is formed through the following process:

Phase 1

On the network shown in [Figure 1-112](#), OSPF process 1 on DeviceA imports the static route 10.0.0.1 and floods a Type 5 AS-External-LSA in OSPF process 1. After receiving the LSA, OSPF process 1 on DeviceD and OSPF process 1 on DeviceE each calculate a route to 10.0.0.1, with the outbound interfaces being interface1 on DeviceD and interface1 on DeviceE, respectively, and the cost being 102. At this point, the routes to 10.0.0.1 in OSPF process 1 in the routing tables of DeviceD and DeviceE are active.

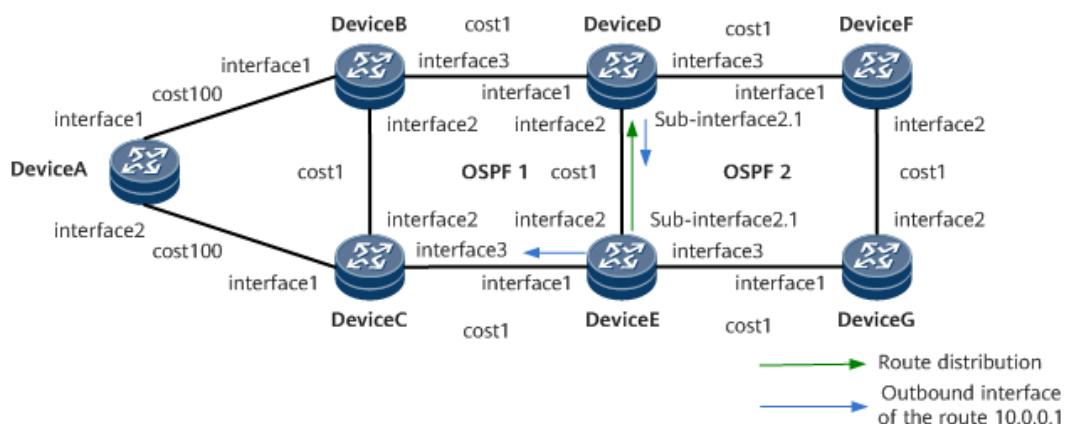

Figure 1-112 Phase 1

Phase 2

In [Figure 1-113](#), DeviceD is configured to import routes from OSPF process 1 to OSPF process 2, and DeviceE is configured to import routes from OSPF process 1 to OSPF process 2. No route-policy is configured for the import, or the configured route-policy is improper. For example, OSPF process 2 on DeviceE imports routes from OSPF process 1 and then floods a Type 5 AS-External-LSA in OSPF process 2. After receiving the LSA, OSPF process 2 on DeviceD calculates a route to 10.0.0.1, with the cost being 2, which is smaller than that (102) of the route calculated by OSPF process 1. As a result, the active route to 10.0.0.1 in the routing table of DeviceD is switched from the one calculated by OSPF process 1 to the one calculated by OSPF process 2, and the outbound interface of the route is sub-interface2.1.

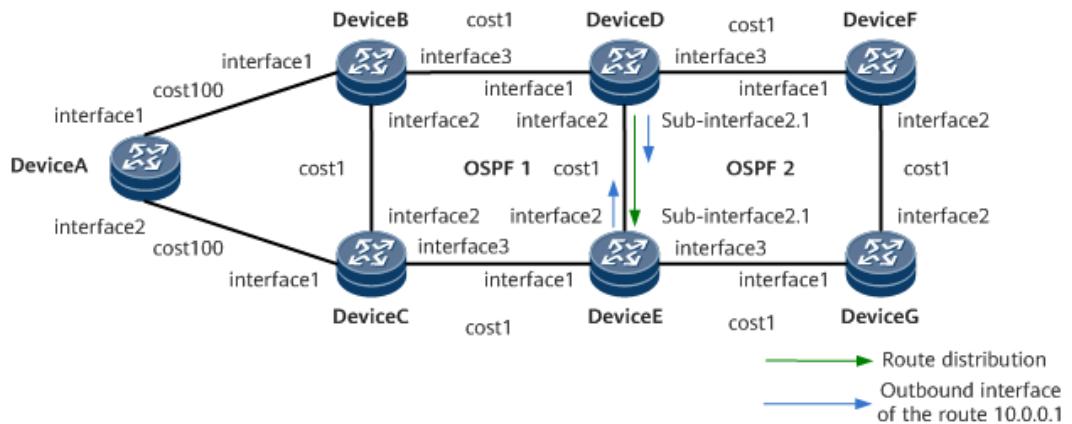

Figure 1-113 Phase 2

Phase 3

In [Figure 1-114](#), DeviceD imports the route from OSPF process 2 to OSPF process 1 and floods a Type 5 AS-External LSA in OSPF process 1. After receiving the LSA, OSPF process 1 on DeviceE recalculates the route to 10.0.0.1. The cost of the route becomes 2, which is smaller than that of the previously calculated route. Therefore, the route to 10.0.0.1 in OSPF process 1 on DeviceE is changed to the route distributed by DeviceD, and the outbound interface is interface 2.

Figure 1-114 Phase 3

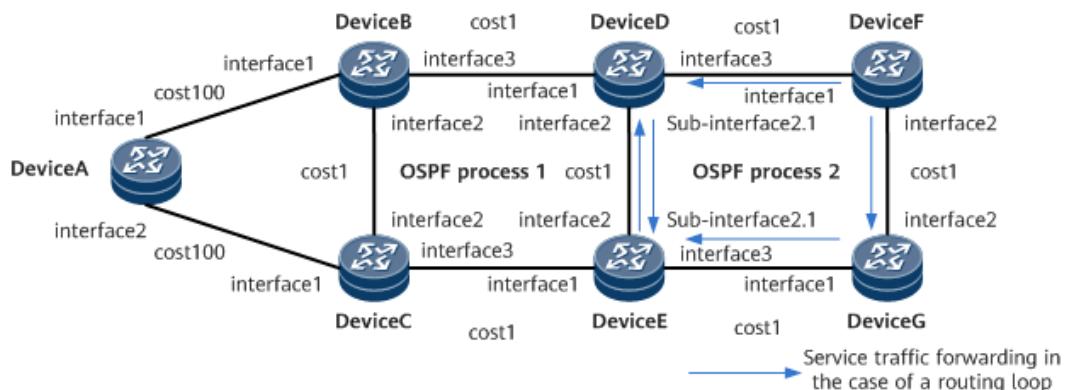

Phase 4

After the route to 10.0.0.1 on DeviceE is updated, OSPF process 2 still imports the route from OSPF process 1 as the route remains active, and continues to distribute/update a Type 5 AS-External-LSA.

As a result, a stable routing loop is formed. Assuming that traffic is injected from DeviceF, **Figure 1-115** shows the traffic flow when the routing loop occurs.

Figure 1-115 Traffic flow when a routing loop occurs

Implementation (OSPF Inter-Process Mutual Route Import)

Routing loop detection for the routes imported between OSPF processes can resolve the routing loops in the preceding scenario.

When distributing a Type 5 AS-External-LSA for an imported route, OSPF also uses a Type 11 extended prefix Opaque LSA to distribute to other devices the Redistribute ID of the device that redistributes the imported route. If the route is redistributed by different protocols through multiple devices, the Redistribute IDs of these protocols on the devices are distributed through a Type 11 extended prefix Opaque LSA. When receiving the Type 11 extended prefix Opaque LSA, a route calculation device saves the Redistribute ID and route information of the route redistribution device. When another process of a route calculation device imports the route, the device checks whether a routing loop occurs according to the route redistribution information. If a routing loop occurs, the device attaches a large route cost to the AS-External-LSA for the imported route so that other

devices preferentially select other paths after learning the route. This prevents routing loops.

Figure 1-116 Typical networking of route import to OSPF

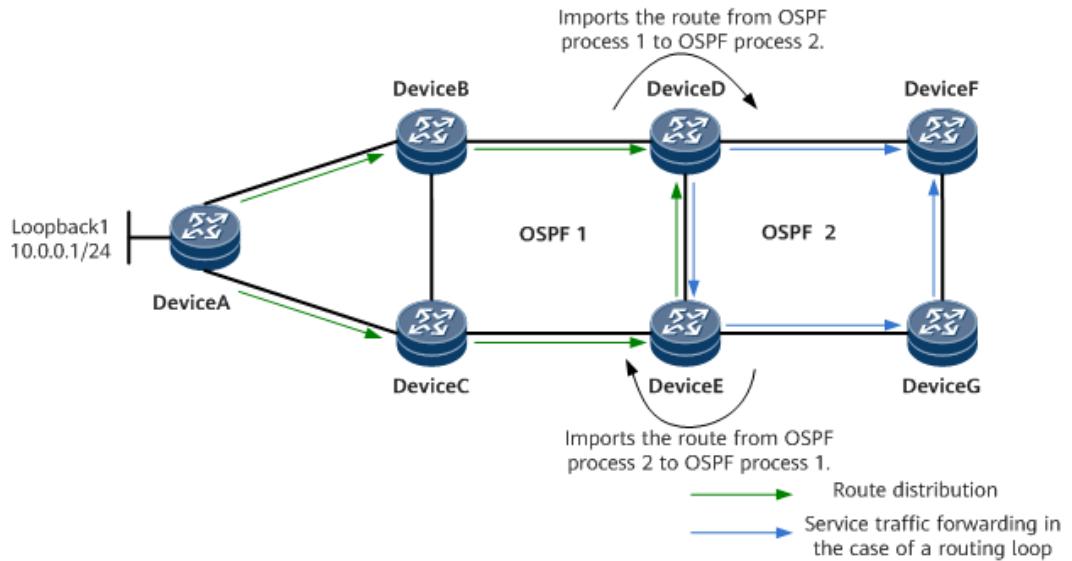

Figure 1-116 is used to describe how a routing loop is detected and resolved.

1. DeviceA distributes its locally originated route 10.0.0.1/24 to DeviceB.
2. DeviceD learns the routes advertised by DeviceB through OSPF process 1. When importing routes from OSPF process 1 to OSPF process 2, DeviceD adds Redistribute ID information to the routes to be distributed through Type 11 extended prefix Opaque LSAs. After learning the Redistribute ID information, DeviceE saves the information in its routing table.
3. DeviceE imports routes from OSPF process 2 to OSPF process 1 and redistributes the routes through OSPF process 1. The corresponding Type 11 extended prefix Opaque LSAs contain the Redistribute ID of OSPF process 1 on DeviceE and the Redistribute ID of OSPF process 2 on DeviceD.
4. OSPF process 1 on DeviceD learns the Redistribute list corresponding to the route distributed by DeviceE and saves the Redistribute list in the routing table. When importing the route from OSPF process 1 to OSPF process 2, DeviceD finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. OSPF process 2 on DeviceD distributes a large cost when redistributing the route so that other devices preferentially select other paths after learning the route. This prevents routing loops.

 NOTE

In the preceding typical networking:

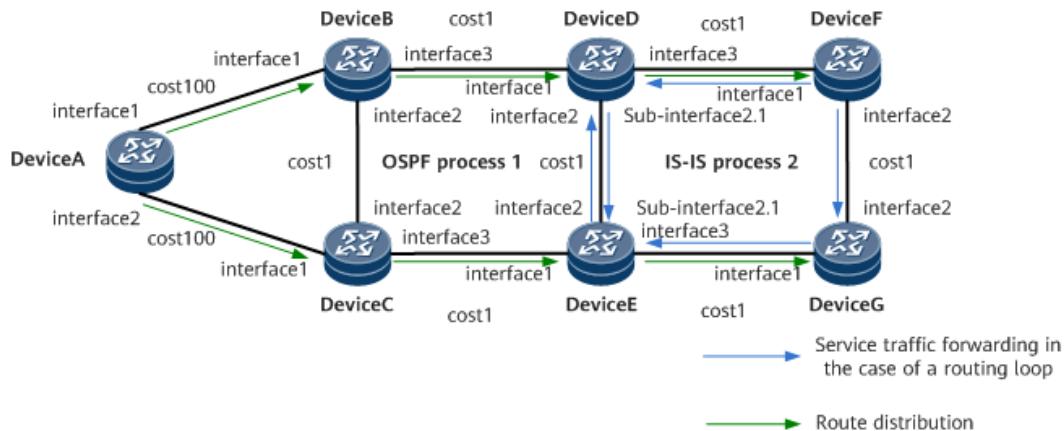

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

Cause (Mutual Route Import Between OSPF and IS-IS)

On the network shown in [Figure 1-117](#), DeviceA, DeviceB, and DeviceC run OSPF process 1, DeviceF and DeviceG run IS-IS process 2, and DeviceD and DeviceE run both processes. Route import between OSPF process 1 and IS-IS process 2 is configured on DeviceD and DeviceE. The ASE routes distributed by OSPF process 1 on DeviceE are re-distributed back to OSPF process 1 on DeviceD through IS-IS process 2. As the costs of the routes newly distributed by DeviceD are smaller, they are preferentially selected by OSPF process 1, resulting in routing loops.

Figure 1-117 Traffic flow when a routing loop occurs during route import between OSPF and IS-IS

Implementation (Mutual Route Import Between OSPF and IS-IS)

The following uses the networking shown in [Figure 1-117](#) as an example to describe how a routing loop is detected and resolved.

1. DeviceD learns the route distributed by DeviceB through OSPF process 1 and imports the route from OSPF process 1 to IS-IS process 2. When IS-IS process 2 on DeviceD distributes route information, it uses the extended prefix sub-TLV to distribute the Redistribute ID of IS-IS process 2 through an LSP. IS-IS process 2 on DeviceE learns the route distributed by DeviceD and saves the Redistribute ID distributed by IS-IS process 2 on DeviceD to the routing table during route calculation.
2. DeviceE imports the route from IS-IS process 2 to OSPF process 1 and uses an E-AS-External-LSA to distribute the Redistribute ID of OSPF process 1 on

DeviceE when distributing route information. Similarly, after OSPF process 1 on DeviceD learns the route from DeviceE, DeviceD saves the Redistribute ID distributed by OSPF process 1 on DeviceE to the routing table during route calculation.

3. When importing the route from OSPF process 1 to IS-IS process 2, DeviceD finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. IS-IS process 2 on DeviceD distributes a large cost when distributing the imported route. Because IS-IS has a higher preference than OSPF ASE, this does not affect the route selection result or resolve the routing loop.
4. DeviceE imports the route from IS-IS process 2 to OSPF process 1, finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. OSPF process 1 on DeviceE distributes a large cost when distributing the imported route so that other devices preferentially select other paths after learning the route. This prevents routing loops.

NOTE

In the preceding typical networking:

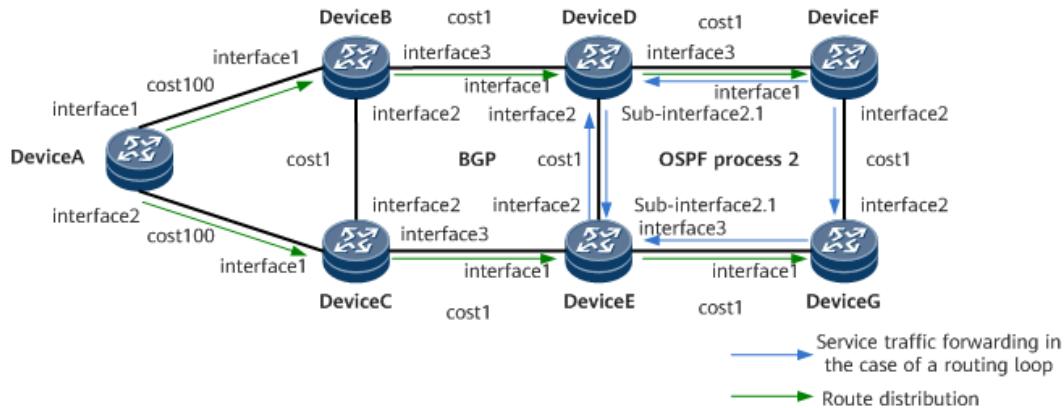

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

Cause (Mutual Route Import Between OSPF and BGP)

On the network shown in [Figure 1-118](#), DeviceA, DeviceB, and DeviceC run a BGP process, DeviceF and DeviceG run OSPF process 2, and DeviceD and DeviceE run both processes. A BGP peer relationship is established between DeviceD and DeviceE. Route import between BGP and OSPF process 2 is configured on DeviceD and DeviceE. DeviceE imports routes from BGP to OSPF process 2 for distribution. DeviceD imports routes from OSPF process 2 to BGP so that the routes are re-distributed back to BGP. Because no route-policy is configured for the import or the configured route-policy is improper, the route newly distributed by DeviceD may be selected as the optimal route by BGP, causing a routing loop.

Figure 1-118 Traffic flow when a routing loop occurs during route import between OSPF and BGP

Implementation (Mutual Route Import Between OSPF and BGP)

The following uses the networking shown in [Figure 1-118](#) as an example to describe how a routing loop is detected and resolved.

1. DeviceD learns the route distributed by DeviceB through BGP and imports the BGP route to OSPF process 2. When DeviceD distributes the imported route through OSPF process 2, it uses a Type 11 extended prefix Opaque LSA to distribute the Redistribute ID of OSPF process 2 on DeviceD. DeviceE learns the route distributed by DeviceD through OSPF process 2 and saves the Redistribute List distributed by DeviceD through OSPF process 2 to the routing table when calculating routes.
2. After DeviceE imports routes from OSPF process 2 to BGP, the Redistribute ID information of OSPF process 2 is inherited by the generated BGP routes, and routing loop attributes are generated and distributed. After BGP on DeviceD learns the routes distributed by DeviceE, DeviceD saves the routing loop attributes distributed by BGP on DeviceE in the routing table for route calculation.
3. When importing the routes from BGP to OSPF process 2, DeviceD finds that the Redistribute list of the routes contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. OSPF process 2 on DeviceD distributes a large link cost when distributing the imported route. Because OSPF has a higher preference than BGP, this does not affect the route selection result or resolve the routing loop.
4. After learning the route distributed by OSPF on DeviceD, DeviceE imports the route to BGP. Upon finding that the Redistribute list of the route contains its own Redistribute ID, DeviceE considers that a routing loop is detected and reports an alarm. When BGP on DeviceE distributes the route, it reduces the preference of the route. In this way, other devices preferentially select other paths after learning this route, preventing routing loops.

NOTE

In the preceding typical networking:

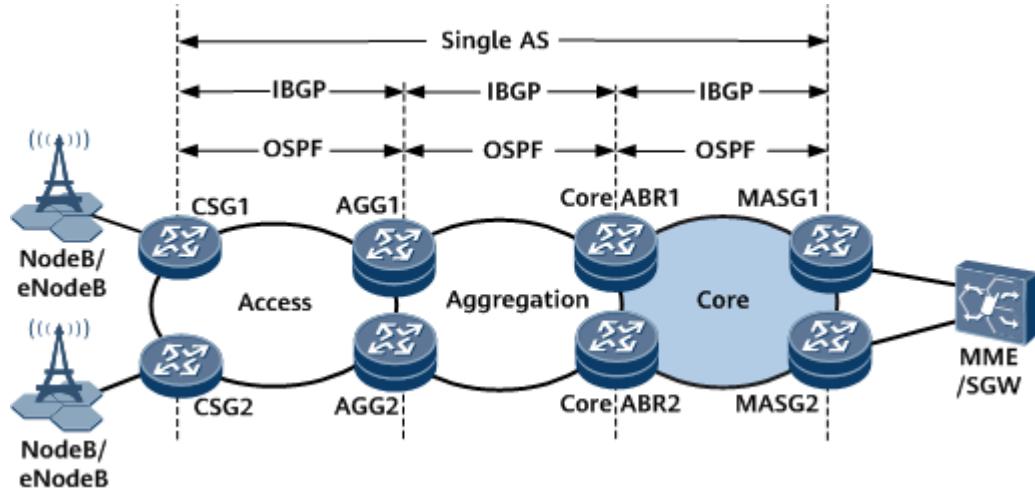

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

Usage Scenario

Figure 1-119 shows a typical intra-AS seamless MPLS network. If the OSPF process deployed at the access layer differs from that deployed at the aggregation layer, OSPF inter-process mutual route import is usually configured on AGGs so that routes can be leaked between the access and aggregation layers. In this case, a routing loop may occur between AGG1 and AGG2. If routing loop detection for OSPF is configured on AGG1 and AGG2, routing loops can be quickly detected and other routes can be preferentially selected, preventing routing loops.

Figure 1-119 Routing protocol deployment on the intra-AS seamless MPLS network

1.1.4.2 OSPF Configuration

By building OSPF networks, you can enable OSPF to discover and calculate routes in an AS. OSPF is applicable to large-scale networks with hundreds of routers.

1.1.4.2.1 Overview of OSPF

Open Shortest Path First (OSPF), which is developed by the IETF, is a link-state IGP. OSPF is widely used in access networks and MANs.

Definition

Open Shortest Path First (OSPF) is a link-state Interior Gateway Protocol (IGP) developed by the Internet Engineering Task Force (IETF).

OSPF version 2 (OSPFv2) is intended for IPv4. OSPF version 3 (OSPFv3) is intended for IPv6.

NOTE

In this document, OSPF refers to OSPFv2, unless otherwise stated.

Purpose

Before the emergence of OSPF, the Routing Information Protocol (RIP) was widely used as an IGP on networks. RIP is a distance-vector routing protocol. Due to its slow convergence, routing loops, and poor scalability, RIP is gradually being replaced with OSPF.

Typical IGPs include RIP, OSPF, and Intermediate System to Intermediate System (IS-IS). **Table 1-46** describes differences among the three typical IGPs.

Table 1-46 Differences among RIP, OSPF, and IS-IS

Item	RIP	OSPF	IS-IS
Protocol type	IP layer protocol	IP layer protocol	Link layer protocol
Application scope	Applies to small networks with simple architectures, such as campus networks.	Applies to medium-sized networks with several hundred routers supported, such as enterprise networks.	Applies to large networks, such as Internet service provider (ISP) networks.
Routing algorithm	Uses a distance-vector algorithm and exchanges routing information over the User Datagram Protocol (UDP).	Uses the shortest path first (SPF) algorithm to generate a shortest path tree (SPT) based on the network topology, calculates shortest paths to all destinations, and exchanges routing information over IP.	Uses the SPF algorithm to generate an SPT based on the network topology, calculates shortest paths to all destinations, and exchanges routing information over IP. The SPF algorithm runs separately in Level-1 and Level-2 databases.
Route convergence speed	Slow	Less than 1 second	Less than 1 second

Item	RIP	OSPF	IS-IS
Scalability	Not supported	Supported by partitioning a network into areas	Supported by defining router levels

Benefits

OSPF offers the following benefits:

- Wide application scope: OSPF applies to medium-sized networks with several hundred routers, such as enterprise networks.
- Network masks: OSPF packets can carry masks, and therefore the packet length is not limited by natural IP masks. OSPF can process variable length subnet masks (VLSMs).
- Fast convergence: When the network topology changes, OSPF immediately sends link state update (LSU) packets to synchronize the changes to the link state databases (LSDBs) of all routers in the same autonomous system (AS).
- Loop-free routing: OSPF uses the SPF algorithm to calculate loop-free routes based on the collected link status.
- Area partitioning: OSPF allows an AS to be partitioned into areas, which simplifies management. Routing information transmitted between areas is summarized, which reduces network bandwidth consumption.
- Equal-cost routes: OSPF supports multiple equal-cost routes to the same destination.
- Hierarchical routing: OSPF uses intra-area routes, inter-area routes, Type 1 external routes, and Type 2 external routes, which are listed in descending order of priority.
- Authentication: OSPF supports area-based and interface-based packet authentication, which ensures packet exchange security.
- Multicast: OSPF uses multicast addresses to send packets on certain types of links, which minimizes the impact on other devices.

1.1.4.2.2 Configuration Precautions for OSPF

Feature Requirements

Table 1-47 Feature requirements

Feature Requirements	Series	Models
<p>1. When the primary next hop is a TE tunnel, microloop avoidance is not calculated.</p> <p>2. For routes with a single route source, load balancing is not supported during microloop avoidance. During microloop avoidance, only one next hop with a strict label stack or a single outbound interface is delivered to the product. After the microloop avoidance period expires, normal convergence entries are delivered.</p> <p>If multiple nodes advertise the same route, load balancing may be performed between the next hop with microloop avoidance and the common next hop.</p> <p>3. The length of the label stack is limited based on the interface capability of the board. The maximum length is 10. If the number of hops exceeds 10, the system does not enter the microloop avoidance state and directly delivers the converged path.</p> <p>4. No microloop avoidance entry is generated on the interface whose label stack capability is 0 or 255.</p> <p>5. Private networks are not supported.</p> <p>6. IP route microloop avoidance is not supported.</p> <p>7. In a broadcast network switchback scenario, if there is more than one neighbor on the switchback link, the device cannot wait for the neighbor labels of multiple neighbors. The microloop avoidance may fail.</p> <p>8. SRs on the entire network must be able to advertise neighbor labels,</p> <p>9. If the link for traffic switchback lacks a neighbor label, path calculation is delayed after traffic switchback. If no neighbor label is received within a certain period of time, microloop avoidance fails. During the delay calculation, a microloop avoidance label stack is delivered for the current path.</p> <p>10. Multiple nodes advertise the same route prefix. When the optimal source node changes</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

Feature Requirements	Series	Models
<p>due to a switchover or switchback, the next hop of the prefix changes. If the SR next hop of the new optimal source node remains unchanged, the microloop avoidance path is not calculated.</p> <p>11. Parallel tags are not supported.</p>		

Feature Requirements	Series	Models
<p>1. Rules for selecting a node label advertised by an OSPF TI-LFA P node are as follows:</p> <ul style="list-style-type: none"> a) The prefix label with the N flag advertised by the P node is preferred. For inter-area or imported routes, the prefix label with the A flag must be set. b) Prefix label of the smallest SID of the prefix with a single route source on the P node c) The P node preferentially selects the route prefix with a single route source. If the route prefix has multiple route sources, ensure that the P node is the only optimal source. If routes with a single route source and prefix labels for load balancing cannot be selected, the prefix labels for load balancing advertised by multiple nodes can be preferentially selected as P SIDs. However, the node SIDs of Ps that advertise the same route and work in load balancing mode can only be used to protect anycast prefixes, and the PQs of anycast prefixes must be the same. d) A node that does not support SR cannot function as a P node. A node that does not advertise prefix labels cannot function as a P node. <p>2. In the case of IP load balancing, OSPF does not calculate the TI-FRR backup path even if there is only one primary prefix label tunnel.</p> <p>3. OSPF anycast prefix label, which is used to calculate the TI-FRR backup path.</p> <ul style="list-style-type: none"> a) Anycast prefix labels and IP routes share virtual nodes when multiple nodes advertise the same routes. b) A maximum of 256 virtual nodes are supported. c) The number of anycast prefix label sources cannot exceed 16. <p>4. In TI-LFA scenarios, TI-LFA calculates routes in RLFA scenarios (that is, PQs overlap and PQ nodes are not neighboring nodes). If no node label is configured for PQ nodes, TI-LFA calculation fails. This is a configuration error and remote LFA calculation is not performed.</p> <p>5. If the cost of the backup path is greater than or equal to 65535, OSPF considers the path unreachable and does not select the path</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

Feature Requirements	Series	Models
whose cost is greater than or equal to 65535 as the backup path.		
After SR LSP strict check is configured, the SR capability of a node is strictly checked when LSPs are calculated from the current node to all nodes. If SR-LDP interworking has been deployed on the network, OSPF SR-LDP interworking may fail, causing traffic interruptions.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
OSPF checks whether a neighbor in the full state exists in the backbone area before advertising a default route to the stub area.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
When a device in an NSSA generates an NSSA LSA based on an imported external route, the device preferentially uses the IP address of a loopback interface in the NSSA as the forwarding address (FA). If no loopback interfaces exist in the NSSA, the device selects the IP address of a non-loopback interface. As a result, the downstream device may fail to implement load balancing using routes even when links with the same cost exist.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
OSPF advertises default routes to an NSSA only when neighbor relationships in the Full state exist in the backbone area or default routes of another protocol or of another OSPF process exist in the same VPN instance on the device, and the nssa default-route-advertise command is run.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

Feature Requirements	Series	Models
<p>1. The mapping SID priority is not supported. All mapping SIDs are processed based on the default priority.</p> <p>2. On the TI-LFA protection path, all devices from the source node to the Q node must support segment routing, and an LDP path must be available from the Q node to the destination node.</p> <p>3. Anycast FRR cannot be implemented for SR routes mapped to mapping SIDs. Anycast protection cannot be implemented between SR routes mapped to mapping SIDs or between SR routes mapped to mapping SIDs and common SR routes.</p> <p>4. SR routes mapped to mapping SIDs do not support remote anti-microloop.</p> <p>5. In cross-process and cross-protocol scenarios, the ASBR functions as an interworking stitching node, and the MappingSid mapping needs to be configured on the process to which the route is imported. Properly plan configurations.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>Penultimate hop popping (PHP) causes SR interworking to fail.</p> <p>Plan the configuration properly.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>SR interworking takes effect only when a mapping SID with an IP prefix with a 32-bit mask is used. SR interworking does not take effect for mapping SIDs with IP prefixes of non-32-bit masks. SR interworking does not take effect for mapping SIDs with IP prefixes of non-32-bit masks.</p> <p>Plan the configuration properly.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

Feature Requirements	Series	Models
<p>In SR-LDP interworking scenarios, FRR does not take effect in some scenarios. For example:</p> <p>In the SR-to-LDP direction, the Q node and all NEs on the path before the Q node must have the SR capability,</p> <p>In the LDP-to-SR interworking FRR scenario, PQ node and all NEs on the path before the PQ path must have the LDP capability.</p> <p>Plan the configuration properly.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>In an OSPF loop detection scenario, when the maximum cost is advertised due to a loop, the apply cost command does not take effect.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>The network types of the interfaces on both ends of an OSPF neighbor relationship must be the same so that the interfaces can learn routes after the neighbor relationship is established. Otherwise, the neighbor relationship cannot be established and routes cannot be calculated.</p> <p>You are advised to use the same network type at both ends.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>In OSPF session CAR scenarios, OSPF neighbors in multiple areas on the same interface cannot be distinguished on the forwarding plane. Therefore, they share the same session CAR entry.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

Feature Requirements	Series	Models
<p>Constraints on the association between BFD and cost values of OSPF broadcast links</p> <p>1) When there is only one neighbor, the neighbor is not deleted when BFD goes Down, and the OSPF LSDB component is notified that the neighbor enters the BFD-associated cost state.</p> <p>2) This function is not supported when there are multiple neighbors.</p> <p>When the number of neighbors changes from one to multiple, the neighbor in the BFD Down state is deleted and the OSPF LSDB component is notified that the neighbor is deleted.</p> <p>It is recommended that only one neighbor relationship be established on an OSPF broadcast network.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>SBFD does not take effect in SR-LDP interworking scenarios because SBFD does not take effect in LDP scenarios.</p> <p>Plan the configuration properly.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>In an OSPF loop detection scenario, after a loop is removed, the loop cannot be automatically removed and the alarm cannot be automatically cleared. Manual intervention is required. After the routing policy or route tag is correctly configured, run the clear route loop-detect ospf alarm-state command to exit the loop state and clear the alarm.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>In OSPF loop detection scenarios, only loops caused by inter-process route import between two devices can be detected. If more than two devices import routes between processes, loops cannot be detected.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
<p>In OSPF loop detection scenarios, loop detection cannot be performed on aggregated routes or NSSA routes.</p>	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

Feature Requirements	Series	Models
In OSPF loop detection scenarios, incorrect detection may be triggered when a router ID conflict occurs, including intra-AS router ID conflict and inter-AS router ID conflict.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
In OSPF loop detection scenarios, a single process can perform loop detection for a maximum of 100,000 routes. If the number of routes exceeds 100,000, loop detection cannot be performed.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
OSPF loop detection depends on the Opaque capability of OSPF in a process. If the Opaque capability is not enabled, OSPF loop detection does not take effect. In this case, you need to manually enable the Opaque capability of OSPF.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
In OSPF loop detection scenarios, loops can be detected for the default route advertised by the default-route-advertise command but self-healing cannot be achieved.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X
After the device is restarted, if the BFD session of the local device or its neighbor is in Admin Down state, the OSPF status is not affected. When the BFD session is renegotiated, if the BFD detection status reported by BFD is Down (used to be Up), the OSPF neighbor is set to Down. In other cases, the OSPF status is not affected.	NetEngine 8000 X	NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X

1.1.4.2.3 Configuring Basic OSPF Functions

Before constructing OSPF networks, you need to configure basic OSPF functions.

Usage Scenario

When OSPF is configured on multiple routers in the same area, most configuration data, such as the timer, filter, and aggregation, must be planned uniformly in the area. Incorrect configurations may cause neighboring routers to

fail to send messages to each other or even causing routing information congestion and self-loops.

The OSPF-relevant commands that are configured in the interface view take effect regardless of whether OSPF is enabled. After OSPF is disabled, the OSPF-relevant commands also exist on interfaces.

Pre-configuration Tasks

Before configuring basic OSPF functions, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.

(Optional) Configuring OSPF Short-Timeout Neighbor Enhancement

OSPF short-timeout neighbor enhancement improves neighbor stability in scenarios where there are many short-timeout neighbors.

Usage Scenario

If the configured interval at which an interface sends Hello packets is less than 10s, many OSPF short-timeout neighbors may exist. (For details about setting the interval, see [Setting the Interval at Which Hello Packets Are Sent](#).) In this case, if the device has poor performance, and the CPU usage is high or a switchover is performed, the neighbors may be unstable due to scheduling issues. To improve the stability of short-timeout neighbors in scenarios where there are more than 150 OSPF and OSPFv3 short-timeout neighbors, you can configure the short-timeout neighbor enhancement function, which increases the OSPF short-timeout neighbor specification.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf short-timeout neighbor enhancement**

OSPF short-timeout neighbor enhancement is configured.

- NOTE**
- If the device has more than 150 short-timeout neighbors and this function is configured or deleted when the CPU usage is high, the neighbors may be intermittently disconnected. If this function is required, you are advised to perform this step before [configuring an OSPF process](#).
 - After this step is performed, short-timeout neighbor enhancement takes effect for both OSPF and OSPFv3.

Step 3 Run **commit**

The configuration is committed.

----End

Enabling OSPF

After an OSPF process is created, a router ID is configured for the router, an interface on which OSPF runs and the area to which the interface belongs are specified, routes can be discovered and calculated in the AS.

Context

OSPF on the router requires a router ID. The router ID is a 32-bit unsigned integer, which uniquely identifies the router in the AS. To ensure the stability of OSPF, manually set the router ID of each router during network planning.

OSPF prevents the link state database (LSDB) size from unexpectedly growing by partitioning an AS into different areas. An area is regarded as a logical group, and each group is identified by an area ID. At the border of an area resides the router instead of a link. A network segment (or a link) belongs to only one area. The area to which each OSPF interface belongs must be specified.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id] [router-id router-id] ***

An OSPF process is started, and the OSPF view is displayed.

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports OSPF multi-instance. To run OSPF in a VPN instance, run the **ospf [process-id] [router-id router-id | vpn-instance vpn-instance-name] *** command.

- The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports OSPF multi-process. Processes can be classified by service type. The routers exchange packets regardless of process IDs.
- **router-id router-id** specifies the router ID of the router.

By default, the router automatically selects the IP address of an interface as the router ID. When configuring the router ID, ensure that the router ID is unique in an AS. You can configure the IP address of an interface as the router ID.

NOTE

Each router ID in an OSPF process must be unique. Otherwise, no OSPF neighbor relationships can be established, and routing information is incorrect.

If a router ID conflict occurs, perform either of the following operations:

- Run the **ospf router-id router-id** command to configure a new router ID.
- Run the **undo ospf router-id auto-recover disable** command to enable the router ID automatic recovery function. After the function is enabled, the system automatically allocates a new router ID if a router ID conflict occurs.

 NOTE

- If the automatic recovery function is enabled and a router ID conflict occurs between indirectly connected routers in one OSPF area, the conflicting router ID is replaced with a newly calculated one, regardless of whether the conflicting router ID was manually configured or automatically generated.
- The system can replace a router ID in a maximum of three attempts in case the router ID conflict persists.

After a router ID is replaced, the **reset ospf [process-id] process** command needs to be run to validate the new router ID.

- If a VPN instance is specified, the OSPF process belongs to this VPN instance. If a VPN instance is not specified, the OSPF process belongs to the public-network instance.

You can run the **description** command to configure a description for the OSPF process for easier identification.

Step 3 Run **area area-id**

The OSPF area view is displayed.

OSPF areas are classified as a backbone area (with area ID 0) or non-backbone areas. The backbone area forwards inter-area routing information. The routing information exchanged between non-backbone areas must be forwarded through the backbone area.

You can run the **description** command to configure a description for the OSPF area for easier identification.

Step 4 To configure OSPF, you can configure the network segments included in an area or enable OSPF on an interface.

- To configure the network segments included in an area, run the **network address wildcard-mask [description text]** command, in which **description** specifies the description of the area.

OSPF runs on an interface only when both of the following conditions are met:

- The mask length of the interface's IP address is greater than or equal to that specified in the **network** command.

 NOTE

If *wildcard-mask* in the **network** command are all 0s and the IP address of the interface is the same as the IP address specified in the **network address** command, OSPF is also enabled on the interface.

- The interface's primary IP address belongs to the network segment specified in the **network** command.

By default, OSPF uses a host route with a 32-bit mask to advertise the IP address of a loopback interface, regardless of the mask length configured for the IP address. To allow a loopback interface to advertise network-segment routes, its network type must be set to NBMA or broadcast in the interface view. For details on how to set the network type, see [Configuring Network Types for OSPF Interfaces](#).

- Enable OSPF on an interface.

- a. Run the **quit** command twice to return to the system view.
- b. Run the **interface interface-type interface-number** command to enter the interface view.
- c. Run the **ospf enable [process-id] area area-id** command to enable OSPF on the interface. The specified area ID can be a decimal integer or in the format of an IPv4 address. Regardless of the specified format, the area ID is displayed as an IPv4 address.

Step 5 Run commit

The configuration is committed.

----End

(Optional) Configuring an Interface to Fill in DD Packets with Its Own MTU

You can configure an interface to fill in the Interface MTU field of a DD packet with the interface MTU.

Context

To improve compatibility with a non-Huawei device, an OSPF-enabled Huawei device adds the MTU 0 in DD packets to be sent and does not check the MTUs in received DD packets, thereby allowing an OSPF neighbor relationship to be set up even if the two ends have different MTU settings.

However, under the default configuration, the non-Huawei device may discard an OSPF packet received from the Huawei device if the actual MTU in the packet is greater than the MTU of the non-Huawei device. If an LSU is discarded, an OSPF neighbor relationship can still be set up, but the routing information carried in the LSU fails to be learned, causing service interruption.

To resolve this issue, run the **ospf mtu-enable** command to configure an interface to add the actual MTU in DD packets to be sent and check whether the MTU in a received DD packet is greater than the local MTU. If the interface MTU settings of the local and remote ends are different, an OSPF neighbor relationship cannot enter the Full state. In this manner, MTU inconsistency can then be identified in time.

NOTICE

Setting the MTU in a DD packet will have the neighbor relationship reestablished.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run interface interface-type interface-number

The interface view is displayed.

Step 3 Run ospf mtu-enable

The interface is configured to fill in a DD packet with the interface MTU and check whether the MTU in the DD packet from the neighboring router exceeds the MTU of the local router.

Step 4 Run commit

The configuration is committed.

----End

(Optional) Creating OSPF Virtual Links

This section describes how to create logical links between backbone areas and to ensure the OSPF network connectivity.

Context

After OSPF areas are deployed, OSPF route updates between non-backbone areas are transmitted through the backbone area. Therefore, OSPF requires that all non-backbone areas be connected to a backbone area and backbone areas be connected as well. However, these requirements may not be met due to various limitations. OSPF virtual links can be configured to solve the problem.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ospf [*process-id*]

The OSPF view is displayed.

Step 3 Run area *area-id*

The OSPF area view is displayed.

Step 4 Run vlink-peer *router-id* [**dead** *dead-interval* | **hello** *hello-interval* | **retransmit** *retransmit-interval* | **trans-delay** *trans-delay-interval* | **smart-discover** | [**simple** [**plain** *plain-text* | [**cipher**] *cipher-text*] | { **md5** | **hmac-md5** | **hmac-sha256** } [**key-id** { **plain** *plain-text* | [**cipher**] *cipher-text* }] | **authentication-null** | **keychain** *keychain-name*]] *

A virtual link is created.

This command must be run on the other end of the virtual link as well.

The default parameter values are recommended when a virtual link is configured. If the network has special requirements, change the parameter values as required. Suggested parameter configurations are as follows:

- The smaller the **hello** value, the faster the router detects network topology changes, and the more network resources are consumed.
- If the value of **retransmit** is too small, unnecessary LSA retransmission may occur. It is recommended that you set a large value on a low-speed network.
- The authentication modes of a virtual link and the backbone area must be the same.

Step 5 Run commit

The configuration is committed.

----End

(Optional) Configuring the router to Comply with Route Selection Rules Defined in a Standard Protocol

You can configure the router to comply with the route selection rule defined in RFC 1583 or RFC 2328.

Context

RFC 2328 and RFC 1583 define route selection rules differently. After enabling OSPF on the router, you can configure the device to comply with route selection rules defined in either standard protocol as required. By default, the router complies with the route selection rules defined in RFC 1583. If you want the device to comply with the other protocol, you need to configure the device to comply with the rules defined in RFC 2328. Such configurations ensure that all OSPF-enabled devices in an AS comply with the same route selection rules defined in the same standard protocol.

If both intra-area and inter-area paths to an ASBR exist on a network, the default rules for selecting a path to the ASBR are as follows:

1. In RFC 1583 compatibility mode:
 - If the area IDs of the intra-area and inter-area paths to the ASBR are the same, intra-area paths are preferred.
 - If the area IDs of intra-area and inter-area paths to the ASBR are different, the path with the smallest cost is preferred; if their costs are the same, the path with the largest area ID is preferred.
2. In RFC 1583 non-compatibility mode:
 - If the area IDs of the intra-area and inter-area paths to the ASBR are the same and the paths belong to non-backbone areas, intra-area paths are preferred.
 - If the area IDs of the intra-area and inter-area paths to the ASBR are the same and the paths belong to the backbone area, the path with the smallest cost is preferred; if their costs are the same, load balancing is supported.
 - If the area IDs of the intra-area and inter-area paths to the ASBR are different, intra-area paths that belong to non-backbone areas are preferred; if intra-area paths belong to the backbone area, the path with the smallest cost is preferred; if their costs are the same, the path with the largest area ID is preferred.

 NOTE

If devices of different vendors or different series of devices of the same vendor are deployed on the same network, the rules for selecting a path to an ASBR among intra-area and inter-area paths may vary according to the mode (RFC 1583 compatibility mode or RFC 1583 non-compatibility mode). In this case, routing loops may occur. To prevent the routing loops, you can set the path selection rules to the default ones.

To prevent routing loops, ensure that all devices on the network use the same path selection rules. If adjustment is performed only on some devices, the adjustment fails to meet expectations. Therefore, exercise caution when adjusting path selection rules.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 (Optional) Run **rfc1583 compatible different-area-path prefer lower-cost**

The device is configured to comply with the default rules in RFC 1583 compatibility mode for selecting a path to an ASBR. That is, if the area IDs of intra-area and inter-area paths to the ASBR are different, the path with the smallest cost is preferred; if their costs are the same, the path with the largest area ID is preferred.

Step 4 Run **undo rfc1583 compatible**

The device is configured to comply with the route selection rule defined in RFC 2328, rather than RFC 1583.

Step 5 (Optional) Run **rfc1583 non-compatible backbone-area-path prefer intra**

The device is configured to comply with the default rules in RFC 1583 non-compatibility mode for selecting a path to an ASBR. That is, if the area IDs of the intra-area and inter-area paths to the ASBR are the same and the paths belong to the backbone area, intra-area paths are preferred.

Step 6 Run **commit**

The configuration is committed.

----End

(Optional) Setting the OSPF Preference

When multiple routing protocols discover routes to the same destination address, you can set the OSPF preference to control the route selection result.

Context

If a router runs multiple dynamic routing protocols at the same time, routing information may be shared and selected among the routing protocols. The system sets a priority for each routing protocol. When multiple routing protocols are used to select routes, the route selected by the routing protocol with a higher priority takes effect.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **preference [ase | inter | intra] { preference | { route-policy route-policy-name | route-filter route-filter-name } }***

A preference is set for OSPF.

- **ase**: indicates the AS external routes for which a preference is set.
- **inter**: indicates the inter-area routes for which a preference is set.
- **intra**: indicates the intra-area routes for which a preference is set.
- **preference**: specifies a preference value for OSPF routes. The smaller the value, the higher the priority.
- **route-policy-name**: specifies a route-policy to filter routes so that the preset preference is applied to the matched routes.
- **route-filter-name**: specifies a route-filter to filter routes so that the preset preference is applied to the matched routes.

Step 4 Run **commit**

The configuration is committed.

----End

(Optional) Restricting the Flooding of OSPF Update LSAs

To maintain stable OSPF neighbor relationships, you can restrict the flooding of update LSAs on a local device, so that its neighbors will not discard Hello packets due to a great number of update LSAs.

Context

If a local device has a large number of neighbors or needs to flood a large number of update LSAs, neighbor routers will receive a large number of update packets within a short time. In this case, neighbor routers are busy with processing the burst update packets and discard the Hello packets that are used to maintain neighbor relationships. As a result, the established OSPF neighbor relationships will be terminated. Then, the neighbor routers will exchange more packets to re-establish the neighbor relationships, exacerbating the problem of excessive packets.

To prevent this problem and ensure the stability of neighbor relationships, you can configure OSPF to restrict the flooding of update LSAs.

NOTE

The parameter settings of this command directly affect the flooding speed. If the parameters are improperly set, LSAs may not be synchronized in time, which affects the routing of the entire network. Therefore, this function is not recommended unless otherwise required.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **flooding-control [number number-value | timer-interval timer-interval-value]^{*}**

OSPF is configured to restrict the flooding of update LSAs.

Step 4 Run **commit**

The configuration is committed.

----End

(Optional) Configuring an Alarm Threshold for the Number of LSAs Learned by OSPF

You can configure an alarm threshold for the number of LSAs learned by OSPF so that an alarm is reported when this threshold is reached or exceeded.

Context

If the number of external routes that OSPF imports and advertises exceeds the routing table capacity of a device, the device may restart unexpectedly. To prevent this problem and ensure that the device runs properly, you can set an alarm threshold for the number of LSAs learned by OSPF and enable overload control.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **maximum received-lsa threshold value [overload-limit]**

An alarm threshold is configured for the number of LSAs learned by OSPF. You can determine whether to enable overload control as required.

- If an alarm threshold is configured but overload control is not, only an alarm is reported when this threshold is reached or exceeded.
- If both an alarm threshold and overload control are configured, an alarm is reported when this threshold is reached or exceeded. In addition, OSPF no longer learns new LSAs when the following conditions are met:
 - The number of LSAs learned by OSPF reaches or exceeds the alarm threshold.
 - The memory is in the danger state, and the memory used by the OSPF LSDB component ranks in the top 3.

- The **ospf memory-overload control** command configuration exists (the corresponding function is enabled by default).

Step 4 Run **commit**

The configuration is committed.

----End

(Optional) Configuring the Maximum Number of Packet Retransmission Attempts

When no response to DD packets, LSU packets, or LSR packets is received, the retransmission mechanism is used and the maximum number of packet retransmission attempts is set to prevent dead loops caused by repeated transmissions.

Context

If no response is received when the maximum number of packet retransmission attempts is reached, the neighbor relationship will be interrupted.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **retransmission-limit [max-number]** The maximum number of OSPF packet retransmission attempts is configured.

Step 4 Run **commit**

The configuration is committed.

----End

(Optional) Setting the Interval at Which LSAs Are Retransmitted Between Adjacent routers

You can set an appropriate interval at which LSAs are retransmitted based on network conditions in order to accelerate convergence.

Context

After sending an LSA to its neighbor, a device waits for a response. If the device does not receive an acknowledgement packet within the Nth LSA retransmission interval, the device retransmits the LSA to the neighbor.

First LSA retransmission interval = Configured interval at which LSAs are retransmitted, which is *interval*

Second LSA retransmission interval = Configured interval at which LSAs are retransmitted, which is *interval*

Third LSA retransmission interval = Configured interval at which LSAs are retransmitted, which is *interval*

Fourth LSA retransmission interval = Configured interval at which LSAs are retransmitted (*interval*) x 2

Fifth LSA retransmission interval = Configured interval at which LSAs are retransmitted (*interval*) x 2²

... ...

Nth LSA Retransmission Interval = Configured interval at which LSAs are retransmitted (*interval*) x 2⁽ⁿ⁻³⁾.

If *interval* x 2⁽ⁿ⁻³⁾ is greater than 30, the Nth LSA retransmission interval is 30.

If the configured interval at which LSAs are retransmitted (*interval*) is greater than 30, the Nth LSA retransmission interval equals *interval*.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

Step 3 Run **ospf timer retransmit interval**

An interval for retransmitting LSAs to the adjacent router is configured.

Set the LSA retransmission interval to a proper value. An excessively short interval will cause unnecessary retransmission. Generally, the interval should be longer than the time taken for round-trip packet transmission between two ends.

The default value is recommended.

Step 4 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After configuring basic OSPF functions, verify information about OSPF neighbors, interfaces, and routes.

Prerequisites

Basic OSPF functions have been configured.

Procedure

- Run the **display ospf [process-id] abr-asbr [router-id]** command in any view to check information about the ABRs and ASBRs of OSPF.
- Run the **display ospf [process-id] cumulative** command in any view to check information about OSPF statistics.

- Run the **display ospf [process-id] peer** command in any view to check information about OSPF neighbors.
- Run the **display ospf [process-id] nexthop** command in any view to check information OSPF next hop information.
- Run the **display ospf [process-id] error [lsa | interface interface-type interface-number]** command in any view to check information about OSPF error information.
- Run the **display ospf [process-id] vlink** command in any view to check information about OSPF virtual links.
- Run the **display ospf [process-id] interface [all | no-peer | interface-type interface-number] [verbose]** command in any view to check information about OSPF interfaces.
- Run the **display ospf [process-id] routing** command in any view to check information about the OSPF routing table.
- Run the **display ospf [process-id] topology [area area-id] [statistics | verbose]** command in any view to check information about the topology calculated for OSPF routes.
- Run the **display ospf [process-id] spf-statistics [verbose]** command in any view to check information about route calculation statistics in OSPF processes.
- Run the **display ospf [process-id] request-queue [interface-type interface-number] [neighbor-id]** command in any view to check information about OSPF request list.
- Run the **display ospf [process-id] retrans-queue [interface-type interface-number] [neighbor-id]** command in any view to check information about OSPF retransmission list.
- Run the **display ospf [process-id] statistics updated-lsa [originate-router advertising-router-id | history]** command in any view to check information about the frequent updates of the LSAs that the LSDB receives
- Run the **display ospf [process-id] statistics maxage-lsa** command to check information about router LSAs that have reached the aging time.
- Run the **display ospf [process-id] router-id conflict** command in any view to check information about router ID conflicts (if any).

----End

1.1.4.2.4 Configuring OSPF on the NBMA or P2MP Network

This section describes how to configure OSPF and modify attributes on the NBMA or point-to-multipoint (P2MP) network to flexibly construct the OSPF network.

Usage Scenario

OSPF classifies networks into four types according to link layer protocols, as shown in [Table 1-48](#).

This section describes only the OSPF configurations that are different on the NBMA network and P2MP network. The OSPF configurations not provided here are applicable to the four types of networks.

Table 1-48 Network types supported by OSPF

Network Type	Characteristic	Default Configuration
Broadcast	On such a type of network, Hello, LSU, and LSAck packets are multicast; DD and LSR packets are unicast.	If the link layer protocol is Ethernet or Fiber Distributed Data Interface (FDDI), OSPF regards the network as a broadcast network by default.
Non-broadcast multiple access (NBMA)	On such a type of network, Hello, DD, LSR, LSU, and LSAck packets are unicast. The NBMA network must be fully meshed. Any two routers on the NBMA network must be directly reachable.	-
Point-to-point (P2P)	On such a type of network, Hello, DD, LSR, LSU, and LSAck packets are multicast.	If the link layer protocol is PPP, Link Access Procedure Balanced (LAPB), OSPF regards the network as a P2P network by default.
Point-to-multipoint (P2MP)	On such a type of network, Hello packets are multicast; DD, LSR, LSU, and LSAck packets are unicast. The mask lengths of the devices on the P2MP network must be the same.	OSPF does not regard a network as a P2MP network by default regardless of any link layer protocol. A P2MP network is forcibly changed from the network of another type.

As shown in **Table 1-48**, OSPF sends packets in different manners on networks of different types. Therefore, the difference between OSPF configurations on the networks lies in the packet sending configurations.

Pre-configuration Tasks

Before configuring session parameters for the OSPF neighbor or adjacency relationship, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- Configure basic OSPF functions.**

Configuring Network Types for OSPF Interfaces

OSPF classifies networks into four types based on the types of link layer protocols. You can configure the network type for an OSPF interface to forcibly change its original network type.

Context

Network types of OSPF interfaces on both ends of a link must be the same. Otherwise, the two interfaces cannot establish an OSPF neighbor relationship. By default, the network type of an interface is determined by the physical interface. The network type of Ethernet interfaces is **broadcast**.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

Step 3 Run **ospf network-type { broadcast | nbma | p2mp | p2p }**

A network type is configured for the OSPF interface.

After a new network type is configured for an interface, the original network type of the interface is replaced.

Configure a network type for the interface as required. For example:

- If the network type of the interface is broadcast but there are routers that do not support multicast addresses on the broadcast network, change the network type of the interface to NBMA.
- If the network type of the interface is NBMA and the network is fully meshed (any two routers are directly reachable), you can change the network type of the interface to broadcast without the need to configure neighboring routers.
- If the network type of the interface is NBMA but the network is not fully meshed, change the network type of the interface to P2MP. In this manner, two routers that are not directly reachable can exchange routing information through a router that is directly reachable to both routers. After the network type of the interface is changed to P2MP, there is no need to manually configure neighboring routers.
- If only two routers run OSPF on the same network segment, changing the network type of the interface to P2MP is recommended.

NOTE

OSPF does not support the configuration on a null interface.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring NBMA Network Attributes

To implement OSPF functions, configure NBMA network attributes.

Procedure

Step 1 (Optional) Set the network type to NBMA.

The NBMA network must be fully meshed. Any two routers on the NBMA network must be directly reachable. In most cases, however, this requirement cannot be met. To resolve this problem, change the network type to P2MP. For details, see [Configuring Network Types for OSPF Interfaces](#).

1. Run **system-view**

The system view is displayed.

2. Run **interface interface-type interface-number**

The interface view is displayed.

3. Run **ospf network-type nbma**

The network type of the OSPF interface is set to NBMA.

4. Run **commit**

The configuration is committed.

Step 2 (Optional) Run **ospf timer poll interval**

The interval at which Hello packets for polling are sent by an NBMA interface is set.

On the NBMA network, after the neighbor relationship becomes invalid, the router sends Hello packets at an interval defined in the polling mechanism.

Step 3 (Optional) Run **ospf dr-priority priovalue**

A priority is configured for the interface to compete for the DR.

The priority of an interface determines whether the interface is qualified to be a DR. The interface with the highest priority is elected as the DR. If the priority of an interface on a device is 0, the device cannot be elected as a DR or BDR. On a broadcast or an NBMA network, you can set the priority of an interface to control the DR or BDR selection. When the DR and BDR are elected on a network segment, they send DD packets to all neighboring nodes and set up adjacencies with all neighboring nodes.

Step 4 (Optional) Run **ospf timer wait interval**

The wait time is configured for the interface.

If no Backup Seen event is received within the *interval*, the DR election starts. Setting a proper value for the wait timer can slow down changes of the DR and BDR on the network, reducing network flapping. When setting the wait timer, note the following points:

- The wait timer takes effect only on broadcast and NBMA interfaces.
- The value of the wait timer cannot be greater than the value of the dead timer.

Step 5 Configure a neighboring router on the NBMA network.

The interface with the network type of NBMA cannot broadcast Hello packets to discover neighboring routers. Therefore, the IP address of a neighboring router must be configured on the process and whether the neighboring router can participate in DR election must be determined on the process.

1. Run **quit**

Exit the interface view.

2. Run **ospf [process-id]**

The OSPF view is displayed.

3. Run **peer ip-address [dr-priority priority]**

A neighbor is configured on the NBMA network.

4. Run **commit**

The configuration is committed.

Step 6 Run **commit**

The configuration is committed.

----End

Configuring P2MP Network Attributes

This section describes how to configure P2MP network attributes to implement OSPF functions.

Procedure

Step 1 Disable the check on the network mask.

The OSPF neighbor relationship cannot be established between the devices with different mask lengths on the P2MP network. After OSPF is disabled from checking the network mask, the OSPF neighbor relationship can be properly established.

1. Run **system-view**

The system view is displayed.

2. Run **interface interface-type interface-number**

The interface view is displayed.

3. Run **ospf network-type p2mp**

The network type of the OSPF interface is configured.

A P2MP network is forcibly changed from another other type of network. For details, see [Configuring Network Types for OSPF Interfaces](#).

4. Run **ospf p2mp-mask-ignore**

OSPF is disabled from checking the network mask on the P2MP network.

5. Run **commit**

The configuration is committed.

Step 2 (Optional) Configure the device to filter the LSA packets to be sent.

When multiple links exist between two devices, you can configure the local device to filter the LSA packets to be sent. This can reduce unnecessary LSA retransmission attempts and save bandwidth resources.

1. Run **system-view**

The system view is displayed.

2. Run **ospf [process-id]**

The OSPF view is displayed.

3. Based on the basic ACL:

- a. Run **filter-lsa-out peer ip-address { all | { summary [acl { acl-number | acl-name }] | ase [acl { acl-number | acl-name }] | nssa [acl { acl-number | acl-name }] } * }**

The local device is configured to filter the LSA packets to be sent on the P2MP network.

b. Run **quit**

Return to the system view.

- c. Run **acl { name basic-acl-name { basic | [basic] number basic-acl-number } | [number] basic-acl-number } [match-order { config | auto }]**

The ACL view is displayed.

- d. Run **rule [rule-id] [name rule-name] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name] ***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:
If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

4. Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After OSPF attributes are set on networks of different types, you can check OSPF neighbor and interface information.

Prerequisites

OSPF attributes have been configured on networks of different types.

Procedure

- Run the **display ospf [process-id] interface [all | no-peer | interface-type interface-number] [verbose]** command to check information about OSPF interfaces.
- Run the **display ospf [process-id] peer** command to check information about OSPF neighbors.
- Run the **display ospf brief** command to check the interval at which Hello packets are sent on an NBMA network.

----End

1.1.4.2.5 Adjusting OSPF Route Selection

By adjusting OSPF route selection, you can enable OSPF to meet the requirements of complex networks.

Usage Scenario

In real world situations, you can configure an OSPF route selection rule by setting OSPF route attributes to meet the requirements of complex networks.

- Set the cost of an interface. The link connected to the interface with a smaller cost value preferentially transmits routing information.
- Configure equal-cost routes to implement load balancing.
- Configure a stub router during the maintenance operations such as upgrade to ensure stable data transmission through key routes.
- Suppress interfaces from sending or receiving packets to help select the optimal route.

- Configuring an OSPF interface to automatically adjust the link cost based on link quality that facilitates route selection control and improves network reliability.

Pre-configuration Tasks

Before adjusting OSPF route selection, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- Configure basic OSPF functions.**

Setting the Interface Cost

You can adjust and optimize route selection by setting the OSPF interface cost.

Context

After the OSPF interface costs are set, the interface with a smaller cost value preferentially transmits routing information. This helps select the optimal route.

The OSPF interface cost can be set or calculated based on the interface bandwidth.

External factors may affect the physical bandwidth of links and change the physical bandwidth of interfaces, which in turn affects network performance. To address this problem, you can run the **bandwidth bandwidth** command in the interface view to set configuration bandwidth for the interface, and then run the **bandwidth-config enable** command to enable the device to calculate the cost for the OSPF interface based on the configuration bandwidth of the interface.

Procedure

- Manually configure a cost for an OSPF interface.
 - Run **system-view**
The system view is displayed.
 - Run **interface interface-type interface-number**
The interface view is displayed.
 - Run **ospf cost value**
A cost is configured for the OSPF interface.
 - Run **commit**
The configuration is committed.
- Configure bandwidth-based automatic OSPF interface cost calculation.
The calculation formula is as follows: **Interface cost = Bandwidth reference value/Interface bandwidth**. The integer of the calculation result is used as the cost of the interface. If the result is less than 1, the cost is 1.

 NOTE

Perform the following operations as required:

- To use the bandwidth reference value to determine the interface cost, run the **bandwidth-reference** command.
- To use the interface bandwidth to determine the interface cost, run the **bandwidth** command to set configuration bandwidth for an interface, and then run the **bandwidth-config enable** command to enable the device to calculate the cost for the OSPF interface based on the configuration bandwidth of the interface.
- To use both the bandwidth reference value and interface bandwidth to determine the interface cost, run the preceding three commands.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **bandwidth bandwidth**

Configuration bandwidth is configured for the interface.

d. Run **quit**

Exit the interface view.

e. Run **ospf [process-id]**

The OSPF view is displayed.

f. Run **bandwidth-reference value**

A bandwidth reference value is set.

g. Run **bandwidth-config enable**

Configuration bandwidth of each OSPF interface is allowed to participate in cost calculation for the interface.

 NOTE

- If the **bandwidth** command is not run, the cost of an OSPF interface is calculated based on the physical bandwidth of the interface.
- If the **bandwidth-config enable** command is not run, the cost of an OSPF interface is calculated based on the physical bandwidth of the interface.

h. Run **commit**

The configuration is committed.

- Associate the remaining bandwidth of an OSPF interface with the link cost.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Associate the remaining bandwidth of an OSPF interface with the link cost.

Perform the following operations as needed:

- To associate the remaining bandwidth of an OSPF interface with the link cost, run the **ospf cost value { higher-bandwidth higher-bandwidth-value cost better-cost-value | lower-bandwidth lower-bandwidth-value cost worse-cost-value } *** command.
- To associate the remaining bandwidth of an OSPF multi-area adjacency interface with the link cost, run the **ospf cost costvalue { higher-bandwidth higher-bandwidth-value cost better-cost-value | lower-bandwidth lower-bandwidth-value cost worse-cost-value } * multi-area { area-id-integer | area-id-ipv4 }** command.

d. Run **commit**

The configuration is committed.

----End

Configuring Equal-Cost Routes

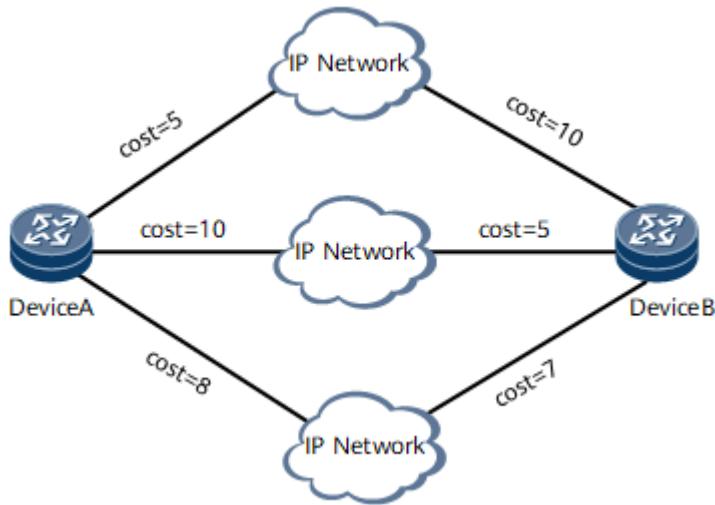

You can set the number of OSPF equal-cost routes and route preference to implement load balancing and adjust route selection.

Context

If the destinations and costs of the multiple routes discovered by one routing protocol are the same, load balancing can be implemented among the routes.

As shown in [Figure 1-120](#), three routes between Device A and Device B that run OSPF have the same costs. The three routes are equal-cost routes for load balancing.

Figure 1-120 Networking diagram of equal-cost routes

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **maximum load-balancing number**

The maximum number of equal-cost routes is set.

If the number of equal-cost routes is greater than *number* specified in the **maximum load-balancing** command, routes are selected for load balancing based on the following criteria:

1. Route preference: Routes with smaller preference values are selected for load balancing. For details about route preference configuration, see [Step 4](#).
2. Interface index: If routes have the same preference, those with greater interface index values are selected for load balancing.
3. Next hop IP address: If routes have the same preference and interface index, those with larger IP addresses are selected for load balancing.

Step 4 (Optional) Run either of the following commands:

- To configure a priority for an equal-cost route, run the **nexthop ip-address weight value** command.

Among equal-cost OSPF routes, those with smaller priority values configured using the **nexthop** command are selected for load balancing.

 - *ip-address* specifies the next hop address of the equal-cost route.
 - *value* specifies the weight of the next hop.
- To configure priorities for the routes with a TE tunnel interface or an IPv4 interface as the outbound interface for route selection if both an IGP-Shortcut-enabled TE tunnel and IP link are available, run the **ecmp prefer { te-tunnel | intact }** command.

Step 5 Run **commit**

The configuration is committed.

----End

Setting the convergence priority for OSPF routes

You can adjust and optimize route selection by setting the convergence priority for OSPF routes.

Context

You can set a convergence priority for the OSPF routes matching the specified IP prefix list. The configuration takes effect on the public network only.

OSPF route calculation, link-state advertisement (LSA) flooding, and LSDB synchronization can be implemented according to the configured priority. Therefore, route convergence can be controlled.

When an LSA meets multiple priorities, the highest priority takes effect.

OSPF calculates LSAs in the sequence of intra-area routes, inter-area routes, and AS external routes and calculates the three types of routes separately according to the specified route calculation priorities. Convergence priorities are critical, high,

medium, and low. To speed up the processing of LSAs with the higher priority, during LSA flooding, the LSAs need to be placed into the corresponding critical, high, medium, and low queues according to priorities.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ip ip-prefix ip-prefix-name [index index-number] { permit | deny } ipv4-address mask-length [match-network] [greater-equal greater-equal-value] [less-equal less-equal-value] [description text]**

An IP prefix list is configured.

Step 3 Run **ospf [process-id]**

The OSPF view is displayed.

Step 4 Run **prefix-priority { critical | high | medium } ip-prefix ip-prefix-name**

The convergence priority for OSPF routes is set.

Step 5 Run **commit**

The configuration is committed.

----End

Configuring a Stub Router

To ensure that a route is not interrupted during flapping-triggering maintenance operations such as upgrade, you can configure a router as a stub router to allow traffic to bypass the route on the stub router.

Context

After a stub router is configured, the route on the stub router will not be preferentially selected. After the route cost is set to the maximum value 65535, traffic generally bypasses the router. This ensures an uninterrupted route on the router during maintenance operations such as upgrade.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **stub-router [[on-startup [interval]] | [include-stub] | [external-lsa [external-lsa-metric]] | [summary-lsa [summary-lsa-metric]]] ***

A stub router is configured.

 NOTE

The stub router configured in this manner is irrelevant to the router in the stub area.

Step 4 (Optional) Run **maximum-link-cost cost**

The maximum cost of OSPF is set.

Step 5 Run **commit**

The configuration is committed.

----End

Suppressing an Interface from Receiving and Sending OSPF Packets

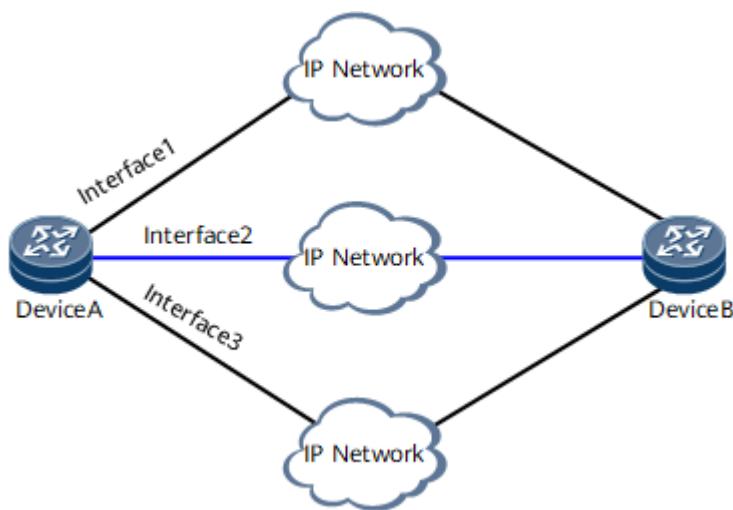

After an interface is suppressed from receiving and sending OSPF packets, routing information can bypass a specific router and the local router can reject routing information advertised by another router.

Context

Suppressing an interface from receiving and sending OSPF packets helps routing information to bypass a specific router and enables the local router to reject routing information advertised by another router. This ensures that an optimal route is provided.

For example, there are three routes between DeviceA and DeviceB, as shown in [Figure 1-121](#). To allow the route with the outbound interface being Interface 2 to be preferred, you can suppress Interface 1 and Interface 3 from receiving and sending OSPF packets.

Figure 1-121 Network diagram of suppressing the interfaces from sending and receiving OSPF packets

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **silent-interface { all | interface-type interface-number }**

An interface is suppressed from receiving and sending OSPF packets.

The same interface in different processes can be suppressed from sending and receiving OSPF packets, but the **silent-interface** command is valid only for the OSPF interface in the local process.

After an OSPF interface is configured to be in the silent state, the interface can still advertise its direct routes. Hello packets on the interface, however, cannot be forwarded. Therefore, no neighbor relationship can be established on the interface. This can enhance the networking adaptability of OSPF and reduce system resource consumption.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring an OSPF Interface to Automatically Adjust the Link Cost

Configuring an OSPF interface to automatically adjust the link cost based on link quality facilitates route selection control and improves network reliability.

Context

A bit error refers to the deviation between a bit that is sent and the bit that is received. The bit error rate (BER) refers to the number of bit errors divided by the total number of bits transferred during a studied time interval. During data transmission, a high BER will degrade or even interrupt services in extreme cases.

To prevent this problem, configure OSPF interfaces to automatically adjust link costs based on link quality so that unreliable links are not used by the optimal routes.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

Step 3 Run **ospf enable [process-id] area area-id**

OSPF is enabled on the interface.

Step 4 Run **ospf link-quality low incr-cost { cost | max-reachable }**

The OSPF interface is configured to automatically adjust the link cost based on link quality.

 NOTE

The *cost* parameter specifies the link cost adjustment value. After this parameter is specified:

- If the link quality changes to **low**, the link cost equals the original link cost plus the adjustment value. The maximum link cost allowed is 65535.
- If the link quality recovers from **low**, the original link cost applies.

Step 5 Run **commit**

The configuration is committed.

----End

Configuring a Fallback Cost for an Eth-Trunk Interface

A fallback cost of an Eth-Trunk interface helps adjust route selection dynamically.

Context

After an Eth-trunk member interface goes down, the OSPF cost value is automatically adjusted. When an Eth-trunk member interface becomes invalid, the remaining bandwidth may fail to meet user requirements, causing service loss. In this fault scenario, the cost of the Eth-Trunk can be dynamically adjusted to a larger value so that traffic is transmitted through other paths. When the interface bandwidth is less than the fallback bandwidth threshold, the device changes the interface cost to the configured fallback cost in time so that a better transmission path is selected. When the bandwidth of an Eth-Trunk interface is greater than or equal to the configured fallback bandwidth threshold, cost-fallback does not take effect.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface eth-trunk *trunk-id***

The Eth-Trunk interface view is displayed.

Step 3 Run **ospf cost-fallback *fallbackcost* *threshold* *fallbackbw***

A fallback cost is configured for an Eth-Trunk interface.

Step 4 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After OSPF route selection is adjusted, you can check OSPF routing table and interface information.

Prerequisites

OSPF route selection has been adjusted.

Procedure

- Run the **display ospf [process-id] interface [all | no-peer | interface-type interface-number] [verbose]** command to check information about OSPF interfaces.
- Run the **display ospf [process-id] routing** command to check information about the OSPF routing table.
- Run the **display ospf [process-id] ecmp-group** command to check information about OSPF ECMP groups

----End

1.1.4.2.6 Controlling OSPF Routing Information

You can control the advertising and receiving of OSPF routing information and import routes of other protocols.

Pre-configuration Tasks

Before controlling OSPF routing information, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPF functions](#).

Configuring OSPF to Import External Routes

Importing the routes discovered by other routing protocols can enrich OSPF routing information.

Context

When a device on an OSPF network needs to access a device running a non-OSPF routing protocol, the device needs to import the routes of the non-OSPF routing protocol into the OSPF network.

OSPF provides loop-free intra-area routes and inter-area routes; however, OSPF cannot prevent external routing loops. Therefore, exercise caution when configuring OSPF to import external routes.

Perform the following operations on the router that functions as the ASBR running OSPF:

NOTICE

OSPF and other dynamic routing protocols such as IS-IS and BGP often import routes from each other. If no routing policy is configured or a routing policy is incorrectly configured on a device where IS-IS, OSPF, and BGP import routes from each other, a Layer 3 routing loop may occur due to a route selection result change. As a result, services are compromised. For details about the cause of the loop, see [Routing Loop Detection for Routes Imported to OSPF](#).

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ospf [process-id]

The OSPF view is displayed.

Step 3 Run import-route { bgp [permit-ibgp] | direct | rip [process-id-rip] | static | unr | isis [process-id-isis] | ospf [process-id-ospf] } [{ inherit-cost | cost cost } | tag tag | type type | route-policy route-policy-name | route-filter route-filter-name | no-sid] *

The device is configured to import routes from another protocol.

Step 4 (Optional) Run default { cost { cost | inherit-metric } | tag tag | type type } *

The default values of parameters (the cost, number of routes, tag, and type) are set for imported routes.

When OSPF imports external routes, you can set default values for some additional parameters, such as the cost, number of routes to be imported, route tag, and route type. The route tag is used to identify the protocol-related information. For example, it can be used to differentiate AS numbers carried in BGP routes imported by OSPF.

NOTE

You can run one of the following commands to set the cost of the imported route. The following commands are listed in descending order of priorities.

- Run the **apply cost** command to set the cost of a route.
- Run the **import-route** command to set the cost of the imported route.
- Run the **default** command to set the default cost of the imported route.

Step 5 (Optional) Run any of the following commands as required:

- Based on a basic ACL:

- a. Run **filter-policy { acl-number| acl-name acl-name } export [direct | static | unr | bgp | { rip | isis | ospf } [process-id]]**

The device is configured to filter the routes imported in step [Step 3](#) so that only the matched routes are advertised.

- b. Run **quit**

Return to the system view.

- c. Run **acl { name basic-acl-name { basic | [basic] number basic-acl-number } | [number] basic-acl-number } [match-order { config | auto }]**

The ACL view is displayed.

- d. Run **rule [rule-id] [name rule-name] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name] ***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:

If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

e. Run **ospf [process-id]**

The OSPF view is displayed.

- Based on an IP prefix list:

Run **filter-policy ip-prefix ip-prefix-name export [direct | static | unr | bgp | { rip | isis | ospf } [process-id]]**

The device is configured to filter the routes imported in step **Step 3** so that only the matched routes are advertised.

OSPF filters the imported routes. OSPF uses Type 5 LSAs to carry routes that meet the filtering conditions and advertises these Type 5 LSAs.

You can specify the parameter **protocol [process-id]** to filter the routes of a certain routing protocol or a certain OSPF process. If **protocol [process-id]** is not specified, OSPF filters all imported routes.

The **import-route** command cannot be used to import external default routes.

Step 6 Run **import-route limit limit-number [threshold-alarm { upper-limit upper-limit-value | lower-limit lower-limit-value } *]**

The maximum number of LSAs generated when OSPF imports routes is set.

If OSPF imports a large number of external routes and advertises them to a device with a small routing table capacity, the device may restart unexpectedly. To address this problem, set a limit on the number of LSAs generated when OSPF imports external routes. You can check the overload status based on the value of the **Current status** field in the **display ospf brief** command output.

- Normal: The number is less than or equal to the lower alarm threshold.
- Approach limit: The number is approaching (reaching or exceeding 90% of) the upper alarm threshold.
- Exceed limit: The number has reached or exceeded the limit.

Ensure that *upper-limit-value* is greater than or equal to *lower-limit-value*.

Step 7 Run **commit**

The configuration is committed.

----End

Configuring OSPF to Import a Default Route

The default route is widely applied on the OSPF network to reduce routing entries in the routing table and filter specific routing information.

Context

On the area border and AS border of an OSPF network generally reside multiple routers for next-hop backup or traffic load balancing. A default route can be configured to reduce routing entries and improve resource usage on the OSPF network.

OSPF default routes are generally applied to the following scenarios:

1. An ABR in an area advertises Type 3 LSAs carrying the default route within the area. routers in the area use the received default route to forward inter-area packets.
2. An ASBR in an AS advertises Type 5 or Type 7 LSAs carrying the default route within the AS. routers in the AS use the received default route to forward AS external packets.

When no exactly matched route is discovered, the router can forward packets through the default route.

The priorities of the default routes corresponding to Type 3 LSAs are higher than those of the routes corresponding to Type 5 or Type 7 LSAs.

The advertising mode of OSPF default routes is determined by the type of the area to which the default routes are imported, as shown in [Table 1-49](#).

Table 1-49 Default route advertising mode

Area Type	Generated By	Advertised By	LSA Type	Flooding Area
Common area	The default-route-advertise command	ASBR	Type 5 LSA	Common area
Stub area	Automatically	ABR	Type 3 LSA	Stub area
NSSA	The nssa [default-route-advertise] command	ASBR	Type 7 LSA	NSSA
	Automatically	ABR	Type 3 LSA	NSSA
Totally NSSA	Automatically	ABR	Type 3 LSA	NSSA

Perform the following steps on the ASBR running OSPF.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **default-route-advertise [[always | permit-calculate-other] | cost cost | type type | { route-policy route-policy-name | route-filter route-filter-name } | distribute-delay delay-time | permit-preference-less-than preference-val] ***

The default route is imported to the OSPF process.

To prevent loops, you are advised to use the **permit-preference-less-than** parameter to prevent the import of activated default routes with low priorities. This parameter is used only when the **always** parameter is not specified.

Configure the default route for the NSSA. For details, see [1.1.4.2.15 Configuring an NSSA](#).

Step 4 Run **commit**

The configuration is committed.

----End

Configuring Route Summarization

When a large-scale OSPF network is deployed, you can configure route summarization to reduce routing entries.

Context

Route summarization on a large-scale OSPF network reduces routing entries, minimizes system resource consumption, and maintains system performance. In addition, if a specific link frequently alternates between Up and Down, the links not involved in the route summarization will not be affected, which prevents route flapping and improves network stability.

Procedure

- Configure ABR route summarization.
 - a. Run **system-view**

The system view is displayed.
 - b. Run **ospf [process-id]**

The OSPF view is displayed.
 - c. Run **area area-id**

The OSPF area view is displayed.
 - d. Run **abr-summary ip-address mask [[advertise | [cost { cost-value | inherit-minimum }] | [hold-max-cost hours] | [generate-null0-route]] * | [not-advertise | [cost { cost-value | inherit-minimum }] | [hold-max-cost hours]] * | [generate-null0-route | [advertise] | [cost { cost-value | inherit-minimum }] | [hold-max-cost hours]] *]**

OSPF ABR route summarization is configured.
 - e. Run **commit**

The configuration is committed.
- Configure ASBR route summarization.
 - a. Run **system-view**

The system view is displayed.
 - b. Run **ospf [process-id]**

The OSPF view is displayed.
 - c. Run **asbr-summary ip-address mask [[not-advertise | generate-null0-route] | tag tag-value | cost cost-value | distribute-delay interval] *]**

OSPF route summarization is configured on the ASBR.
 - d. Run **commit**

The configuration is committed.

 NOTE

After route summarization is configured, the routing table of the local OSPF device remains unchanged. The routing table on an OSPF neighbor, however, contains only one summary route and no specific routes. This summary route stays in the routing table until all the summarized specific routes on the network are withdrawn.

----End

Configuring OSPF to Filter LSAs in an Area

Filtering LSAs in an area can prevent unnecessary LSA transmission. This reduces the size of the LSDB on the neighboring router and speeds up network convergence.

Context

After filtering conditions are set for the incoming or outgoing Type 3 LSAs (Summary LSAs) in an area, only the Type 3 LSAs that meet the filtering conditions can be received or advertised.

This function is applicable only to the ABR.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **area area-id**

The OSPF area view is displayed.

Step 4 Filter incoming or outgoing Type 3 LSAs in the area.

- Filter outgoing Type 3 LSAs in the area. Run any of the following commands as required:

- Based on the basic ACL:

- i. Run **quit**

Return to the system view.

- ii. Run **acl { name basic-acl-name { basic | [basic] number basic-acl-number } | [number] basic-acl-number } [match-order { config | auto }]**

The ACL view is displayed.

- iii. Run **rule [rule-id] [name rule-name] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name] ***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:

If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

iv. Run **ospf [process-id]**

The OSPF view is displayed.

v. Run **area area-id**

The OSPF area view is displayed.

vi. Run **filter { acl-number | acl-name acl-name } export**

The outgoing Type 3 LSAs of the local area are filtered based on the basic ACL.

- Based on the IP prefix list:

Run **filter ip-prefix ip-prefix-name export**

Outgoing Type 3 LSAs in the area are filtered based on the IP prefix list.

- Based on the route-policy:

Run **filter route-policy route-policy-name export**

Outgoing Type 3 LSAs in the area are filtered based on the route-policy.

- Based on a route-filter:

Run **filter route-filter route-filter-name export**

Outgoing Type 3 LSAs in the area are filtered based on the route-filter.

- Filter incoming Type 3 LSAs in the area. Run any of the following commands as required:

- Based on the basic ACL:
 - i. Run **quit**
Return to the system view.
 - ii. Run **acl { name basic-acl-name { basic | [basic] number basic-acl-number } | [number] basic-acl-number } [match-order { config | auto }]**
The ACL view is displayed.
 - iii. Run **rule [rule-id] [name rule-name] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name] ***
An ACL rule is configured.
When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.
When a filter-policy of a routing protocol is used to filter routes:
 - o If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
 - o If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
 - o If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
 - o If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
 - o Routes can be filtered using a blacklist or whitelist:
If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.
Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.
Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.
- iv. Run **ospf [process-id]**
The OSPF view is displayed.
- v. Run **area area-id**
The OSPF area view is displayed.
- vi. Run **filter { acl-number | acl-name acl-name } import [include-abr-summary]**

Incoming Type 3 LSAs in the area are filtered based on the basic ACL.

- Based on the IP prefix list:

Run **filter ip-prefix ip-prefix-name import [include-abr-summary]**

Incoming Type 3 LSAs in the area are filtered based on the IP prefix list.

- Based on the route-policy:

Run **filter route-policy route-policy-name import [include-abr-summary]**

Incoming Type 3 LSAs in the area are filtered based on the route-policy.

- Based on the route-filter:

Run **filter route-filter route-filter-name import [include-abr-summary]**

Incoming Type 3 LSAs in the area are filtered based on the route-filter.

Step 5 Run **commit**

The configuration is committed.

----End

Configuring OSPF to Filter LSAs to Be Sent

Filtering the LSAs to be sent on the local router can prevent unnecessary LSA transmission. This reduces the size of the LSDB on the neighboring device and speeds up network convergence.

Context

When multiple links exist between two devices, you can configure the local device to filter the LSAs to be sent. This prevents unnecessary LSA transmission and saves bandwidth resources.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

Step 3 Based on the basic ACL:

1. Run **quit**

Return to the system view.

2. Run **acl { name basic-acl-name { basic | [basic] number basic-acl-number } | [number] basic-acl-number } [match-order { config | auto }]**

The ACL view is displayed.

3. Run **rule [rule-id] [name rule-name] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name] ***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:

If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

4. Run **quit**

Return to the system view.

5. Run **interface interface-type interface-number**

The interface view is displayed.

6. Run **ospf filter-lsa-out { all | { summary [acl { acl-number| acl-name }] | ase [acl { acl-number| acl-name }] | nssa [acl { acl-number| acl-name }] } * }**

The OSPF interface is enabled to filter outgoing LSAs.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring OSPF to Filter Received Routes

After a filtering policy is configured for the OSPF routes that need to be delivered to the routing management module, only the routes that match the policy will be added to the routing table.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Perform any of the following operations as required:

- Based on the basic ACL:

- a. Run **quit**

Return to the system view.

- b. Run **acl { name basic-acl-name { basic | [basic] number basic-acl-number } | [number] basic-acl-number } [match-order { config | auto }]**

The ACL view is displayed.

- c. Run **rule [rule-id] [name rule-name] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name] ***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:

If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

- d. Run **ospf** [*process-id*]
The OSPF view is displayed.
- e. Run **filter-policy** { *acl-number* | **acl-name** *acl-name* } **import**
An import policy is configured to filter received routes.
- Based on the IP prefix list:
Run **filter-policy ip-prefix** *ip-prefix-name* **import**
An import policy is configured to filter received routes.
- Based on the route-policy:
Run **filter-policy route-policy** *route-policy-name* [**secondary**] **import**
An import policy is configured to filter received routes.
- Based on the route-filter:
Run **filter-policy route-filter** *route-filter-name* [**secondary**] **import**
An import policy is configured to filter received routes.

OSPF is a link-state dynamic routing protocol, with routing information carried in the link status advertisement (LSA). Therefore, the **filter-policy import** command cannot be used to filter the advertised or received LSAs. The **filter-policy import** command is used to filter the routes calculated by OSPF. Only the routes that match the filtering rules are added to the routing table and can be advertised. Routes that do not match the filtering rules can be added to the OSPF routing table but not to the routing information base (RIB) and cannot be advertised.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring OSPF to Filter the Routes to Be Advertised

After a filtering policy is configured for routes imported by OSPF, only the routes that match the policy can be advertised.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf** [*process-id*]

The OSPF view is displayed.

Step 3 Set the conditions to filter routes to be advertised.

Run any of the following commands as required:

- Based on a basic ACL:
 - a. Run **quit**
Return to the system view.
 - b. Run **acl** { **name** *basic-acl-name* { **basic** | [**basic**] **number** *basic-acl-number* } | [**number**] *basic-acl-number* } [**match-order** { **config** | **auto** }]

The basic ACL view is displayed.

- c. Run **rule** [*rule-id*] [**name** *rule-name*] { **deny** | **permit** } [**fragment-type** { **fragment** | **non-fragment** | **non-subseq** | **fragment-subseq** | **fragment-spe-first** }] **source** { *source-ip-address* { *source-wildcard* | **0** | *src-netmask* } | **any** } | **time-range** *time-name* | **vpn-instance** *vpn-instance-name*] *

A rule is configured for the ACL.

When the **rule** command is run to configure rules for a named ACL, only the source address range specified by **source** and the time period specified by **time-range** are valid as the rules.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.
- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.
- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:

Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.

Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.

- d. Run **ospf** [*process-id*]

The OSPF view is displayed.

- e. Run **filter-policy** { *acl-number* | **acl-name** *acl-name* } **export** [**direct** | **static** | **unr** | **bgp**] { **rip** | **isis** | **ospf** } [*process-id*]]

The device is configured to filter the imported routes to be advertised.

- Based on an IP prefix list:

Run **filter-policy ip-prefix** *ip-prefix-name* **export** [**direct** | **static** | **unr** | **bgp** | { **rip** | **isis** | **ospf** } [*process-id*]]

The device is configured to filter the imported routes to be advertised.

- Based on a route-policy:

Run **filter-policy route-policy-name export [direct | static | unr | bgp | { rip | isis | ospf } [process-id]]**

The device is configured to filter the imported routes to be advertised.

Step 4 Run commit

The configuration is committed.

----End

(Optional) Configuring OSPF to Discard Specified LSAs

You can configure a device to discard specified LSAs in an OSPF process.

Context

OSPF can be configured to discard specified LSAs in the following scenarios:

1. When devices on the entire network restart repeatedly due to abnormal LSAs and you have located the LSA that causes protocol restarts, you can configure this function as a last resort to prevent the device from restarting continuously. However, if this function is incorrectly configured, routing loops may occur.
2. If an LSA is identified as an attack packet, which is not supposed to appear in the local area, and has caused serious problems, such as device restarts, you can configure this function to filter out the LSA under the condition that the attack source cannot be located temporarily and that the LSA does not affect topology path computation.
3. If an LSA is identified as an attack packet, which is not supposed to appear in the local area, and it affects topology path computation and has caused serious problems, such as network-wide device restarts, you can configure this function on each device to discard the LSA to prevent it from participating in network-wide calculation.

NOTE

To filter out the LSA that affects topology path computation, you must ensure that it is removed from all the LSDBs on the entire network. Otherwise, routing loops may occur.

4. If an LSA is identified as an unreachable residual LSA and the device that advertised the LSA becomes permanently unreachable, you can configure this function to filter out the LSA upon reception under the condition that the LSA does not affect topology path computation.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ospf [process-id]

The OSPF view is displayed.

Step 3 Run ignore-receive-lsa advertise-router adv-rtr-id [lsa-type type-value [area { area-id | area-idipv4 }]] | link-state-id ls-id] *

The device is configured to discard LSAs of a specified type.

 NOTE

If this command is incorrectly configured, services cannot be restored even if the **undo ignore-receive-lsa advertise-router adv-rtr-id [lsa-type type-value [area { area-id | area-idipv4 }] | link-state-id ls-id] *** command is run. In this case, you may need to reset the process or neighbor to restore services.

You are not advised to run this command to filter out the LSAs that exist on the network as running this command may filter out normal LSAs.

As an attack LSA can have any key, it is difficult to defend against the LSA using this command. Therefore, you are advised to directly isolate the attack source.

This command cannot be used to defend against attacks as it goes against protocol processing rules and affects services. Therefore, exercise caution when running this command.

If the fault is caused by a bug, you are advised to run this command temporarily. After the patch is installed, run the **undo ignore-receive-lsa advertise-router adv-rtr-id [lsa-type type-value [area { area-id | area-idipv4 }] | link-state-id ls-id] *** command immediately and check whether services are affected. If services are affected, re-establish all neighbor relationships to restore services.

Step 4 Run commit

The configuration is committed.

----End

Configuring the Maximum Number of External Routes Supported by the OSPF LSDB

You can set the maximum number of external routes in the LSDB to keep a proper number of external routes.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run ospf [process-id]

The OSPF view is displayed.

Step 3 Run lsdb-overflow-limit number

The maximum number of external routes in the LSDB is set.

If the number of external routes imported by OSPF exceeds the maximum number allowed by the LSDB, the device deletes self-generated non-default external routes to ensure proper forwarding of the other external routes imported by OSPF.

Step 4 Run commit

The configuration is committed.

----End

Verifying the Configuration of OSPF Routing Information Control

After OSPF routing information is controlled, you can check OSPF LSDB information.

Prerequisites

OSPF routing information has been controlled.

Procedure

- Run the **display ospf [process-id] lsdb** command to check information about the OSPF LSDB.
- Run the **display ospf [process-id] asbr-summary [ip-address mask]** command to check information about OSPF route summarization.

----End

1.1.4.2.7 Adjusting the OSPF Network Convergence Speed

By adjusting OSPF timers, you can implement OSPF network convergence speed.

Pre-configuration Tasks

Before adjusting the OSPF network convergence speed, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPF functions](#).

Setting the Interval at Which Hello Packets Are Sent

You can adjust the value of the Hello timer to change the speed of the OSPF neighbor relationship establishment and change the network convergence speed.

Context

Hello packets are periodically sent between OSPF interfaces to establish and maintain neighbor relationships. The intervals set on the interfaces at both ends must be the same. Otherwise, the OSPF neighbor relationship cannot be established.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The OSPF interface view is displayed.

Step 3 Run **ospf timer hello interval [conservative]**

The interval at which Hello packets are sent is set on the interface.

The **conservative** parameter indicates that the conservative mode is enabled for the neighbor dead timer. If the conservative mode is enabled, the value configured for the dead timer using the **ospf timer dead** command takes effect even when the value is less than 10s.

To speed up OSPF convergence in the case of a link failure, configuring BFD for OSPF is recommended. If the remote end does not support BFD for OSPF or the user does not want to have BFD for OSPF enabled, you are advised to specify **conservative** when running the **ospf timer dead** command. In conservative mode, the value set for the dead timer using the **ospf timer dead** command takes effect even if the value is less than 10 seconds; otherwise, route convergence is performed based on the OSPF neighbor dead timer, which takes a long time and has a great impact on services.

NOTE

This interval must not be less than the time taken to perform an active/standby switchover. Otherwise, an intermittent protocol interruption may occur during a switchover. The default timer value is recommended.

Step 4 Run **commit**

The configuration is committed.

----End

Setting the Delay for Transmitting LSAs on an Interface

This configuration is important for low-speed networks.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The OSPF interface view is displayed.

Step 3 Run the **ospf trans-delay delayvalue** command to set the delay for the interface to transmit LSAs.

The LSAs in the LSDB of the local device age with time (increase by 1 each second), but not during transmission. Therefore, an LSA transmission delay needs to be set before LSAs are sent.

Step 4 Run **commit**

The configuration is committed.

----End

Setting the Dead Time of an OSPF Neighbor

If no Hello packet is received from a neighbor within a dead interval, the neighbor is considered Down.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The OSPF interface view is displayed.

Step 3 Run **ospf timer dead interval**

A dead timer is set for OSPF neighbor relationships.

NOTE

If the dead timer is shorter than 10s, the neighbor relationship may be torn down. To prevent this issue, the dead timer of 10 seconds takes effect if the value of **dead interval** configured for OSPF neighbor relationships is less than 10 seconds. However, if the **ospf timer hello** command is run, the **conservative** parameter is specified to enable the conservative mode for the neighbor dead timer, and the configured dead timer is less than 10s, the system still uses the configured value to determine whether a neighbor is down.

Changing the network type will restore both the Hello timer and dead timer to their default values.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring OSPF Sham Hello

With OSPF sham hello, device can exchange Hello and LSU and LSAck packets to maintain OSPF neighbor relationships, which strengthens the neighbor detection mechanism.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **sham-hello enable**

OSPF sham hello is enabled.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring Smart-discover

After Smart-discover is configured, when the neighbor status changes or the DR or BDR on the multiple-access network (broadcast network or NBMA network)

changes, the local router sends Hello packets to its neighbor immediately without waiting for the Hello timer to expire.

Context

Without Smart-discover, when the neighbor status of the router changes or the DR/BDR on the multiple-access network (broadcast or NBMA network) changes, the router does not send Hello packets to its neighbor until the Hello timer expires; after Smart-discover is configured, the router sends Hello packets to its neighbor immediately without waiting for the Hello timer to expire, which speeds up the neighbor relationship establishment and OSPF network convergence.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The OSPF interface view is displayed.

Step 3 Run **ospf smart-discover**

Smart-discover is configured on the interface.

Step 4 Run **commit**

The configuration is committed.

----End

Setting the Interval at Which LSAs Are Updated

You can set the interval at which LSAs are updated based on network connections and router resources.

Context

OSPF sets the interval for updating LSAs to 5s. This prevents network connections or route flapping from consuming excessive network bandwidth or device resources. On a stable network that requires fast route convergence, you can set the interval for updating LSAs to 0 seconds. In this manner, when the topology or a route changes, the change can be immediately advertised to the network through LSAs. This speeds up route convergence on the network. On an unstable network, routes are calculated frequently, consuming excessive CPU resources. In addition, LSAs that describe the unstable topology are frequently generated and transmitted on the unstable network. Due to the frequent processing of such LSAs, the entire network cannot become stable quickly. You can configure an intelligent timer so that the device can dynamically adjust the interval based on the user configuration and frequency of triggering events (such as route calculation) to quickly stabilize the network.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **lsa-originate-interval { 0 | intelligent-timer max-interval start-interval hold-interval [other-type interval] | other-type interval [intelligent-timer max-interval start-interval hold-interval] }**

The interval at which LSAs are updated is configured.

- **intelligent-timer**: uses the intelligent timer to set the update interval for OSPF Type 1 LSAs (router LSAs) and Type 2 LSAs (network LSAs).
- **max-interval**: specifies the maximum interval at which OSPF LSAs are updated, in milliseconds.
- **start-interval**: specifies the initial interval at which OSPF LSAs are updated, in milliseconds.
- **hold-interval**: specifies the hold interval at which OSPF LSAs are updated, in milliseconds.
- **other-type**: sets the update interval for OSPF Type 3 LSAs (network-summary-LSAs), Type 4 LSAs (ASBR-summary-LSAs), and Type 10 LSAs (opaque LSAs).

The interval for updating LSAs is as follows:

1. The initial interval at which LSAs are updated is specified by *start-interval*.
2. The interval at which LSAs are updated for the nth ($n \geq 2$) time equals *hold-interval* $\times 2^{(n - 2)}$.
3. When the interval specified by *hold-interval* $\times 2^{(n - 2)}$ reaches the maximum interval specified by *max-interval*, OSPF updates LSAs at the maximum interval for three consecutive times. Then, OSPF updates LSAs at the initial interval specified by *start-interval*.

Step 4 (Optional) Run **lsa-originate-interval suppress-flapping suppress-interval [threshold threshold]**

The suppression period that takes effect when sent OSPF LSAs flap is configured.

If no flapping occurs in sent OSPF LSAs, you can run the **lsa-originate-interval** command to prevent frequent LSA sending by setting a proper interval at which LSAs are sent. If sent OSPF LSAs flap, you can run the **lsa-originate-interval suppress-flapping** command to set a flapping suppression period. This minimizes the impact of frequent LSA flapping on services. If both of them are configured, the device uses the larger value as the flapping suppression time.

Step 5 Run **commit**

The configuration is committed.

----End

Setting the Interval at Which LSAs Are Received

You can set the interval at which LSAs are received based on network connections and router resources.

Context

In OSPF, the defined interval at which LSAs are received is 1s. This aims to prevent network connections or frequent route flapping from consuming excessive network bandwidth or device resources.

On a stable network that requires fast route convergence, you can cancel the interval at which LSAs are received by setting the interval to 0s. After the interval is set to 0s, topology or route changes can be immediately advertised on the network through LSAs, which speeds up route convergence.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **lsa-arrival-interval { interval | intelligent-timer max-interval start-interval hold-interval }**

The interval at which LSAs are received is set.

- *interval*: specifies the interval at which LSAs are received, in milliseconds.
- **intelligent-timer**: uses the intelligent timer to set the interval at which OSPF router LSAs and network LSAs are updated.
- *max-interval*: specifies the maximum interval at which OSPF LSAs are received, in milliseconds.
- *start-interval*: specifies the initial interval at which OSPF LSAs are received, in milliseconds.
- *hold-interval*: specifies the hold interval at which OSPF LSAs are received, in milliseconds.

The maximum interval for receiving LSAs is as follows:

1. The initial interval at which LSAs are received is specified by *start-interval*.
2. The interval at which LSAs are received for the nth ($n \geq 2$) time equals *hold-interval* $\times 2^{(n - 1)}$.
3. When the interval specified by *hold-interval* $\times 2^{(n - 1)}$ reaches the maximum interval specified by *max-interval*, OSPF receives LSAs at the maximum interval for three consecutive times. Then, OSPF returns to **Step 3.1** and receives LSAs at the initial interval specified by *start-interval*.

Step 4 (Optional) Run **lsa-arrival-interval suppress-flapping suppress-interval [threshold threshold]**

The suppression period that takes effect when received OSPF LSAs flap is configured.

If no flapping occurs among received OSPF LSAs, the configuration of the **lsa-arrival-interval** command prevents the device from frequently receiving LSAs. If received OSPF LSAs flap, the configuration of the **lsa-arrival-interval suppress-**

flapping command reduces the impact of the flapping on services. If both of them are configured, the device uses the larger value as the flapping suppression time.

Step 5 Run **commit**

The configuration is committed.

----End

Setting the Interval for the SPF Calculation

By setting the interval for the SPF calculation, you can save resources consumed by frequent network changes.

Context

When the OSPF LSDB changes, the shortest path needs to be recalculated. If a network changes frequently, the shortest path is calculated accordingly, which consumes a large number of system resources degrades system performance. By configuring an intelligent timer and a proper interval for the SPF calculation, you can prevent excessive system memory and bandwidth resources from being occupied.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **spf-schedule-interval { interval1 | intelligent-timer max-interval start-interval hold-interval [conservative] | millisecond interval2 }**

The interval for SPF calculation is set.

The interval for SPF calculation based on the intelligent timer is described as follows:

1. The initial interval for SPF calculation is specified by *start-interval*.
2. The interval for SPF calculation for the nth ($n \geq 2$) time equals *hold-interval* $\times 2^{(n - 2)}$.
3. After the interval specified by *hold-interval* $\times 2^{(n - 2)}$ reaches the maximum interval specified by *max-interval*, OSPF keeps using the maximum interval for SPF calculation.
4. If no flapping occurs during the interval from the end of the last SPF calculation to the start of the next SPF calculation, and the interval exceeds the maximum interval specified by *max-interval*, the intelligent timer exits.
5. If no flapping occurs in the previous interval but occurs in the current interval, SPF calculation is delayed for a period of *start-interval*. After the SPF calculation is complete, the current interval will be applied when waiting for the next SPF calculation.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring the Function to Suppress the Advertisement of Interface Addresses

This section describes how to configure the function to suppress the advertisement of interface addresses so that interface addresses can be reused.

Procedure

- Configuring the function to suppress the advertisement of all interface addresses in an OSPF process
 - a. Run **system-view**
The system view is displayed.
 - b. Run **ospf [process-id]**
The OSPF view is displayed.
 - c. Run **suppress-reachability**
The device is configured to suppress the advertisement of all interface addresses in an OSPF process.
 - d. Run **commit**
The configuration is committed.
- Configuring an OSPF interface to suppress the advertisement of interface addresses
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface interface-type interface-number**
The OSPF interface view is displayed.
 - c. Run **ospf suppress-reachability**
An OSPF interface to suppress the advertisement of interface addresses is configured.
 - d. Run **commit**
The configuration is committed.

----End

Configuring the Route Calculation Delay Function to Suppress Frequent LSA Flapping

A route calculation delay can suppress frequent OSPF LSA flapping.

Context

Frequent OSPF LSA flapping on the remote device may lead to route flapping on the local device, affecting services. To address this problem, run the **maxage-lsa route-calculate-delay** command to configure the local device to delay route

calculation in the case of frequent OSPF LSA flapping, which suppresses route flapping locally.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **maxage-lsa route-calculate-delay delay-interval**

The route calculation delay function is configured to suppress frequent OSPF LSA flapping.

Step 4 Run **commit**

The configuration is committed.

----End

Disabling Active/Standby Board Switching Triggered by Abnormal OSPF Aging

By default, active/standby board switching triggered by abnormal OSPF aging is enabled. To disable this function, perform this task.

Context

When the local device's aging timer expires, the local device incorrectly clears all Router LSAs received from the peer device, which causes large-scale route flapping and service interruptions. To resolve this issue, active/standby board switching triggered by abnormal OSPF aging is automatically enabled. Such switching is triggered to restore network connections and service traffic when the following condition is met:

(Number of incorrectly cleared Router LSAs/Total number of Router LSAs) × 100%
≥ 80% (Router LSAs are those sent by the peer device to the local device)

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf maxage-lsa auto-protect disable**

Active/standby board switching triggered by abnormal OSPF aging is disabled.

Step 3 Run **commit**

The configuration is committed.

----End

Disabling OSPF LSA Aging Management

By default, the OSPF LSA aging management function is enabled. To disable this function, perform this task.

Context

LSAs are aged out if their LS age field encounters an exception, and this may cause LSA flapping or incorrect route calculation. For example, the actual LSA aging time of a device is 500 seconds and the device receives an LSA with the aging time of 2500 seconds, the LSA is aged too early because LSAs automatically age in 3600 seconds according to the protocol mechanism. To address this issue, the OSPF LSA aging management function is enabled by default. If the aging time in a received LSA is longer than 1800 seconds, OSPF considers the LSA abnormal and changes the aging time to 1700 seconds. This operation is performed for each abnormal LSA until the aging time values of all LSAs in the area are the same. This ensures that routes can be calculated correctly.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **lsa-age refresh disable**

OSPF LSA aging management is disabled.

Step 4 Run **commit**

The configuration is committed.

----End

Setting a Period During Which OSPF Keeps the Maximum Cost in Local LSAs

If a period during which OSPF keeps the maximum cost in local LSAs is configured and an OSPF interface changes from Down to Up, traffic is switched back only when the period elapses.

Context

When an OSPF interface changes from down to up, the OSPF neighbor relationship is re-established. After IGP route convergence is completed, traffic is switched back. In most cases, IGP routes converge quickly. However, many services that depend on IGP routes may require a delayed switchback. In this case, you can run the **ospf peer hold-max-cost** command to specify a period during which OSPF keeps the maximum cost in local LSAs. After the OSPF neighbor relationship reaches the Full state, the traffic forwarding path remains unchanged during the specified period. After this period expires, the normal cost is restored, and traffic is switched back normally.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The OSPF interface view is displayed.

Step 3 Run **ospf peer hold-max-cost timer timer**

A period during which OSPF keeps the maximum cost in local LSAs is set.

Step 4 Run **commit**

The configuration is committed.

----End

Configuring Secure Synchronization

Secure synchronization prevents traffic loss after a device is restarted.

Context

When the routers in an area just finish synchronizing the LSDBs, the LSDBs of these routers are different from each other. As a result, route flapping occurs. You can configure secure synchronization to solve this problem. This, however, may delay the establishment of the OSPF neighbor relationship.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **safe-sync enable**

Secure synchronization is configured.

Step 4 Run **commit**

The configuration is committed.

----End

Verifying the Configuration of the OSPF Network Convergence Speed

After configuring OSPF fast network convergence, verify OSPF brief information.

Prerequisites

OSPF fast convergence has been configured.

Procedure

- Run the **display ospf [process-id] brief** command to check brief information about the specified OSPF process.
- Run the **display ospf [process-id] statistics maxage-lsa** command to check information about router LSAs that have reached the aging time.

----End

1.1.4.2.8 Configuring OSPF Delay Advertisement

With OSPF delay advertisement, intra-domain link delay information can be collected and flooded.

Usage Scenario

Traditional path computation algorithms compute the optimal path to a destination address based on costs. However, the path computed in this way may not have the minimum delay. For services that have stringent requirements on delay, path computation can be performed based on the delay rather than on the cost to ensure that service traffic is transmitted along the path with the minimum delay. After OSPF delay advertisement is configured, OSPF collects and floods intra-domain link delay information and reports the information to the controller through BGP-LS. The controller then computes paths on the P2P network based on delay constraints.

Pre-configuration Tasks

Before configuring delay advertisement, configure TWAMP Light to detect delay information. The configuration is as follows:

- Configure the TWAMP Light controller function on the local end.
 - a. Configure the TWAMP Light client function, and create a test session.
 - i. Run **system-view**
The system view is displayed.
 - ii. Run **nqa twamp-light**
The TWAMP Light view is displayed.
 - iii. Run **client**
The TWAMP Light client function is enabled, and the TWAMP Light client view is displayed.
 - iv. Run **test-session session-id sender-ip sender-ip-address reflector-ip reflector-ip-address sender-port sender-port reflector-port reflector-port [dscp dscp-value | padding padding-length | padding-type padding-type | description description] ***
A measurement session is created on the initiator.
 - v. Run **quit**
Return to the TWAMP Light view.
 - b. Configure the TWAMP Light Sender and start the TWAMP Light performance test.

- i. Run **sender**
The TWAMP Light Sender function is enabled, and the TWAMP Light Sender view is displayed.
 - ii. Run **test start-continual test-session session-id [period { 10 | 100 | 1000 | 30000 }] [time-out time-out]**
Continual measurement is started.
 - iii. Run **commit**
The configuration is committed.
- Configure the TWAMP Light Responder on the peer end.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **nqa twamp-light**
The TWAMP Light view is displayed.
 - c. Run **responder**
The TWAMP Light Responder function is enabled, and the TWAMP Light Responder view is displayed.
 - d. Run **test-session session-id local-ip local-ip-address remote-ip remote-ip-address local-port local-port remote-port remote-port interface { interface-type interface-number | interface-name } [anti-loop-on] [description description]**
A measurement session is created on the responder.
 - e. Run **commit**
The configuration is committed.

For details about how to configure TWAMP Light, see TWAMP Light.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

An OSPF process is created, and the OSPF view is displayed.

process-id specifies an OSPF process. If the *process-id* parameter is not specified, the system creates process 1 by default.

Step 3 Run **opaque-capability enable**

The Opaque capability is enabled on the device.

Step 4 Run **metric-delay [average] [variation] advertisement enable**

Delay advertisement is enabled.

Step 5 (Optional) Run **metric-delay normalize interval interval-value [offset offset-value]**

The link delay normalization function is configured for the OSPF process.

For the delay-based path computation algorithm, the delay differences of links are different, and the differences may be small. However, even if the delay differences are small, only one optimal path can be generated according to the existing SPF algorithm, and load balancing cannot be implemented within a certain delay tolerance range. As a result, link resources on the network cannot be fully utilized. To resolve this problem to the greatest extent, normalization processing may be performed on the link delays with a small difference or a difference within an acceptable range so that load balancing can be implemented and link resources on the network can be fully utilized.

Step 6 (Optional) Run **metric-delay suppress timer *time-value* percent-threshold *percent-value* absolute-threshold *absolute-value***

The delay advertisement suppression function is configured.

Step 7 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After the configuration is complete, verify the configuration.

- Run the **display ospf interface verbose** command to check information about OSPF-enabled interfaces.

1.1.4.2.9 Configuring OSPF Neighbor Relationship Flapping Suppression

OSPF neighbor relationship flapping suppression works by delaying OSPF neighbor relationship reestablishment or setting the link cost to the maximum value.

Usage Scenario

If an interface carrying OSPF services alternates between Up and Down, OSPF neighbor relationship flapping occurs on the interface. During the flapping, OSPF frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, OSPF services, and other OSPF-dependent services, such as LDP and BGP. OSPF neighbor relationship flapping suppression can address this problem by delaying OSPF neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

The following steps are optional, choose them as required.

Pre-configuration Tasks

Before configuring OSPF neighbor relationship flapping suppression, complete the following tasks:

- Configure an IP address for each interface to ensure that neighboring routers are reachable at the network layer.

- **Configure basic OSPF functions.**

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 (Optional) Disable OSPF neighbor relationship flapping suppression globally.

1. Run the **ospf [process-id | router-id router-id]*** command to enter the OSPF view.
2. Run the **suppress-flapping peer disable** command to disable OSPF neighbor relationship flapping suppression.

To disable the function globally, perform this step.

Step 3 Run **interface interface-type interface-number**

The interface view is displayed.

Step 4 (Optional) Run **suppress-flapping peer disable**

OSPF neighbor relationship flapping suppression is disabled on the interface.

To disable the function on one of the interfaces, perform this step.

Step 5 Configure an OSPF neighbor relationship flapping suppression mode, which can be Hold-down or Hold-max-cost mode.

- Hold-down mode:

To configure the Hold-down mode and set its duration, run the **ospf suppress-flapping peer hold-down interval** command.

If flooding and topology changes frequently occur during OSPF neighbor relationship establishment, you can configure the Hold-down mode to prevent OSPF neighbor relationship reestablishment within a period of time. This prevents frequent LSDB synchronization and a large number of packets from being exchanged.

- Hold-max-cost mode:

If user service traffic is frequently switched, you can configure OSPF neighbor relationship flapping suppression to work in Hold-max-cost mode. In this mode, the link cost is set to the maximum value (Max-cost) within a period of time, preventing user service traffic from passing through flapping links.

- a. (Optional) Set the maximum cost for OSPF links.

If OSPF neighbor relationship flapping suppression works in Hold-max-cost mode, the device sets the link cost to the maximum value (Max-cost) within a period of time, preventing service traffic from passing through flapping links.

If the value needs to be modified, perform this step.

- i. Run **quit**

Return to the system view.

- ii. Run **ospf [process-id]**

The OSPF view is displayed.

iii. Run **maximum-link-cost cost**

The maximum cost of OSPF is set.

iv. Run **quit**

Return to the system view.

v. Run **interface interface-type interface-number**

The interface view is displayed.

b. (Optional) Run **ospf suppress-flapping peer hold-max-cost disable**

The Hold-max-cost neighbor relationship flapping suppression mode is disabled.

To disable the Hold-max-cost neighbor relationship flapping suppression mode, perform this step.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

Step 6 Run **ospf suppress-flapping peer { detecting-interval *detecting-interval* | threshold *threshold* | resume-interval *resume-interval* }***

Detection parameters are configured for OSPF neighbor relationship flapping suppression.

- Specify an interval for exiting OSPF neighbor relationship flapping suppression.
If the interval between two successive neighbor relationship states (changing from Full to a non-Full state) is longer than the *resume-interval*, the flapping_count is reset.
- If OSPF neighbor relationship flapping suppression works in Hold-max-cost mode, the value of *resume-interval* indicates the duration of this mode.

The value of *resume-interval* must be greater than that of *detecting-interval*.

You can configure detection parameters for OSPF neighbor relationship flapping suppression on specific interfaces according to network conditions. However, using the default values of these parameters is recommended.

Step 7 Run **quit**

The system view is displayed.

Step 8 Run **commit**

The configuration is committed.

Step 9 Run **quit**

The user view is displayed.

Step 10 Run **reset ospf *process-id* suppress-flapping peer [*interface-type interface-number*] [*notify-peer*]**

Interfaces are forced to exit OSPF neighbor relationship flapping suppression.

 NOTE

Interfaces exit flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding OSPF process is reset.
- An OSPF neighbor is reset using the **reset ospf peer** command.
- OSPF neighbor relationship flapping suppression is disabled globally using the **suppress-flapping peer disable** command in the OSPF view.
- The **reset ospf suppress-flapping peer** command is run.

----End

Verifying the Configuration

Run the **display ospf [process-id] interface interfaceType interfaceNum verbose** command to check the status of OSPF neighbor relationship flapping suppression.

1.1.4.2.10 Disabling OSPF Interface Flapping Suppression

OSPF interface flapping suppression is globally enabled by default. If this function is not needed, you can disable it.

Usage Scenario

If OSPF interfaces frequently alternate between up and down, the interfaces will flap, and protocol packets will be frequently exchanged, affecting OSPF services and other services relying on OSPF. Interface flapping suppression can address this issue. This function allows a device to delay interface state changes to up. If this function is not needed, you can disable it.

Pre-configuration Tasks

Before configuring OSPF interface flapping suppression, [configure basic OSPF functions](#).

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf suppress-flapping interface disable**

OSPF interface flapping suppression is disabled.

Step 3 Run **commit**

The configuration is committed.

----End

Checking the Configuration

Run the **display current-configuration configuration ospf** command to check the status of OSPF interface flapping suppression.

1.1.4.2.11 Configuring Routing Loop Detection for Routes Imported into OSPF

Routing loop detection for routes imported into OSPF enables a device to check whether routes advertised by the device are imported back. If routes advertised by the device are imported back, the device advertises a large link cost for the routes to prevent routing loops.

Usage Scenario

Routing loops may occur when an OSPF process imports routes. If routing loop detection is enabled for routes imported into OSPF on a device and this device detects that it imports a route advertised by itself, it sends this route with a large link cost to other devices. After receiving this route, these devices preferentially select other paths, thereby preventing routing loops.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 (Optional) Run **clear route loop-detect ospf alarm-state**

The routing loop detection alarm state exits, and related alarms are cleared.

NOTE

If the device detects an OSPF routing loop, it reports an alarm. Because the device cannot automatically detect whether the routing loop is eliminated, you need to run this command after the routing loop is eliminated to prevent the device from advertising a large link cost for imported routes and manually clear the OSPF routing loop alarm. If this command is executed when the routing loop has not been eliminated, the alarm is reported again.

Step 3 Run the **route loop-detect ospf enable** command to enable OSPF to detect loops of imported routes. Run the **route loop-detect ospf import-ospf enable** command to enable OSPF to detect loops of imported routes.

NOTE

To reduce the impact of routing loops on services, you are advised to keep routing loop detection enabled for routes imported to OSPF.

Step 4 Run **commit**

The configuration is committed.

----End

1.1.4.2.12 Configuring OSPF Flush Source Tracing

OSPF flush source tracing helps improve troubleshooting efficiency.

Usage Scenario

If network-wide OSPF LSPs are deleted, purge LSPs are flooded, which adversely affects network stability. In this case, source tracing must be implemented to locate the root cause of the fault immediately to minimize the impact. However, OSPF itself does not support source tracing. A conventional solution is isolation

node by node until the faulty node is located, but the solution is complex and time-consuming. To address this problem, enable OSPF flush source tracing.

Pre-configuration Tasks

Before configuring OSPF flush source tracing, complete the following task:

- Configure an IP address for each interface to ensure that neighboring routers are reachable at the network layer.
- [Configure basic OSPF functions](#).

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 (Optional) Run **ospf flush-source-trace disable**

OSPF flush source tracing is disabled globally.

To disable OSPF flush source tracing globally, perform this step.

Step 3 Run **interface interface-type interface-number**

The interface view is displayed.

Step 4 (Optional) Run **ospf flush-source-trace block**

OSPF flush source tracing is disabled on the interface.

To disable OSPF flush source tracing on an interface, perform this step.

Step 5 Run **quit**

The system view is displayed.

Step 6 Run **ospf flush-source-trace port port-number**

A UDP port number is configured for OSPF flush source tracing packets.

An OSPF flush source tracing port is used to send and receive OSPF flush source tracing packets and is represented by a UDP port number.

Step 7 Run **quit**

The user view is displayed.

Step 8 Run **commit**

The configuration is committed.

Step 9 Run **reset ospf process-id flush-source-trace**

OSPF flush source tracing is reset.

If a large number of OSPF flush source tracing statistics exist on a device, you can run the **reset ospf flush-source-trace** command to reset the statistics and restart OSPF flush source tracing. If the command is run, all dynamic source tracing

statistics are deleted, and the device needs to re-negotiate the source tracing capability with neighboring devices.

----End

Verifying the Configuration

Run the **display ospf [process-id] [area area-id] flush-source-trace analysis-info** command to check information about definitely and possibly faulty nodes identified by OSPF flush source tracing.

1.1.4.2.13 Configuring an OSPF Hostname

Compared with router IDs, OSPF hostnames are easier to memorize. Therefore, using hostnames to identify routers can facilitate network management.

Usage Scenario

To facilitate network management, configure hostnames to identify routers.

Either dynamic or static OSPF hostnames can be configured. In dynamic mode, a hostname can be configured on and advertised by the local device. The mapping between the local device's router ID and hostname can then be queried on a remote router that successfully learns this dynamic hostname.

Pre-configuration Tasks

Before configuring a hostname, complete the following tasks:

- Configure an IP address for each interface to ensure that neighboring routers can use the IP addresses to communicate with each other.
- Configure basic OSPF functions.**

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **opaque-capability enable**

The Opaque-LSA function is enabled.

Step 4 Run **hostname host-name**

A dynamic OSPF hostname is configured.

NOTE

If you specify *hostname* in the **hostname** command, the value of *hostname* is advertised as the dynamic hostname. However, if *hostname* is not specified in the command, the hostname specified in the **sysname** command is advertised as the dynamic hostname.

Step 5 Run commit

The configuration is committed.

----End

Verifying the Configuration

Run either of the following commands to check dynamic OSPF hostnames:

- **display ospf [process-id] hostname-table**
- **display ospf [process-id] lsdb [router | network | summary | asbr | ase | nssa | opaque-link | opaque-area] [link-state-id] [originate-router [advertising-router-id] | self-originate | hostname *hostname*] [age { min-value *min-age-value* | max-value *max-age-value* } *]**
- **display ospf [process-id] lsdb [router | network | summary | asbr | ase | nssa | opaque-link | opaque-area] [link-state-id] [originate-router [advertising-router-id] | self-originate] [age { min-value *min-age-value* | max-value *max-age-value* } *] [resolve-hostname]**

1.1.4.2.14 Configuring an OSPF Stub Area

Configuring a non-backbone area as a stub area can reduce routing entries in the area in an AS does not transmit routes learned from other areas in the AS or AS external routes. This reduces bandwidth and storage resource consumption.

Applicable Environment

The number of LSAs can be reduced by partitioning an AS into different areas. To reduce the number of entries in the routing table and the number of LSAs to be transmitted in a non-backbone area, configure the non-backbone area on the border of the AS as a stub area.

Configuring a stub area is optional. A stub area generally resides on the border of an AS. For example, a non-backbone area with only one ABR can be configured as a stub area. In a stub area, the number of entries in the routing table and the amount of routing information to be transmitted greatly decrease.

Note the following points when configuring a stub area:

- The backbone area (Area 0) cannot be configured as a stub area.
- If an area needs to be configured as a stub area, all the routers in this area must be configured with stub attributes using the **stub** command.
- An ASBR cannot exist in a stub area. External routes are not transmitted in the stub area.
- Virtual links cannot exist in the stub area.

Pre-configuration Tasks

Before configuring a stub area, complete the following tasks:

- Configuring IP addresses for interfaces to ensure that neighboring routers are reachable at the network layer

- **Configuring Basic OSPF Functions**

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **area area-id**

The OSPF area view is displayed.

Step 4 Run **stub**

The specified area is configured as a stub area.

- All routers in a stub area must have the **stub** command configuration.
- Running the **stub** command or canceling the configuration may cause the stub area to be updated. The **stub** command configuration on a device can be canceled or the configuration can be performed on new devices in the stub area only after the last area update is complete.

Step 5 (Optional) Run **stub no-summary**

The ABR is prevented from sending Type 3 LSAs to the stub area.

Step 6 (Optional) Run **stub default-route-advertise backbone-peer-ignore**

The ABR is prevented from checking the neighbor status when it generates a default Type 3 LSA and advertises it to the stub area.

Step 7 (Optional) Run **default-cost cost**

A cost is set for the default route advertised to the stub area.

To ensure the reachability of AS external routes, the ABR in the stub area generates a default route and advertises it to non-ABR routers in the stub area.

Step 8 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After configuring the stub area, verify the configuration.

- Run the **display ospf [process-id] lsdb** command to check OSPF LSDB information.
- Run the **display ospf [process-id] peer** command to check information about OSPF neighbors.
- Run the **display ospf [process-id] routing** command to check information about the OSPF routing table.

When routers are in a common area, there are AS external routes in the routing table. After the area where the router resides is configured as a stub area, AS external routes no longer exist in the routing table, and the **ASE** field is displayed as 0 in the command output.

1.1.4.2.15 Configuring an NSSA

Configuring a non-backbone area on the border of an AS as an NSSA can reduce entries in the routing table and the amount of routing information to be transmitted. This section describes how to set the cost of the default route to an NSSA and adjust the selection of the default route.

Usage Scenario

An excessive number of entries in a routing table wastes network resources and causes high CPU usage. To reduce entries in a routing table, configure a non-backbone area on the border of an AS as a stub area or an NSSA to reduce the amount of routing information to be transmitted. For details on how to configure an OSPF stub area, see [1.1.4.2.14 Configuring an OSPF Stub Area](#).

An NSSA is a new type of OSPF area. Neither the NSSA nor the stub area transmits routes learned from other areas in the AS where it resides. Different from the stub area, the NSSA allows AS external routes to be imported and forwarded in the entire AS.

If you want to import AS external routes to an area and prevent these routes from consuming resources, configure the area as an NSSA.

Type 7 link state advertisements (LSAs) are used to carry imported AS external routes in the NSSA. Type 7 LSAs are generated by ASBRs of NSSAs and flooded only in the NSSAs where ASBRs reside. The ABR in an NSSA selects Type 7 LSAs from those received, and translates them into Type 5 LSAs in order to advertise external routes to other areas over the OSPF network.

NOTE

- A Type 7 LSA was introduced to support NSSAs and describe imported external routes.
- Default routes can also be represented by Type 7 LSAs to guide traffic to other ASs.

To configure an area as an NSSA, configure NSSA attributes on all the routers in this area.

Pre-configuration Tasks

Before configuring an NSSA, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring routers are reachable at the network layer.
- [Configure basic OSPF functions](#).

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **area area-id**

The OSPF area view is displayed.

Step 4 Run **nssa [{ default-route-advertise [backbone-peer-ignore] } | no-import-route | no-summary | set-n-bit | suppress-forwarding-address | translator-always | translator-interval interval-value | zero-address-forwarding] ***

The area is configured as an NSSA.

 **NOTE**

- NSSA attributes must be configured on all routers in the NSSA using the **nssa** command.
- Configuring or deleting NSSA attributes may trigger area update and neighbor relationship interruption. You can perform the configuration again or cancel the configuration only after the last area update is complete.

The parameters in the **nssa** command are used in the following scenarios:

- The **default-route-advertise** parameter is used to generate default Type 7 LSAs on the ABR or ASBR and advertise them to the NSSA.
The conditions for generating default Type 7 LSAs and advertising them to the NSSA are as follows:
 - a. Neighbors in Full state and interfaces in Up state must exist in the backbone area.
 - b. The **default-route-advertise** parameter is configured.
 - c. Other default routes (destined for 0.0.0.0) exist in the local routing table.If condition 1 is met, the ABR can generate default Type 7 LSAs and advertise them to the NSSA. If conditions 2 and 3 are met, the ASBR can generate default Type 7 LSAs and advertise them to the NSSA.
- The **backbone-peer-ignore** parameter is used to ignore the check on the neighbor status in the backbone area. That is, the ABR automatically generates default Type 7 LSAs and advertises them to the NSSA as long as an interface that is Up exists in the backbone area, regardless of whether a neighbor in the Full state exists.
- If an ASBR also functions as an ABR, specifying **no-import-route** prevents OSPF from advertising the external routes imported using the **import-route** command to the NSSA.
- To reduce the number of LSAs to be transmitted to the NSSA, specify **no-summary** on an ABR. This prevents the ABR from transmitting Summary LSAs (Type 3 LSAs) to the NSSA.

 **NOTE**

After the **nssa default-route-advertise backbone-peer-ignore no-summary** command is run, the ABR generates both the default Type 7 LSA and default Type 3 LSA as long as the backbone area contains interfaces that are up, regardless of whether neighbor relationships in Full state exist. In this case, the default Type 3 LSA preferentially takes effect.

- After the **set-n-bit** parameter is set, the N-bit is set in the DD packets during the synchronization between the router and neighboring router.
- The **suppress-forwarding-address** parameter sets the forwarding address (FA) of the Type 5 LSAs translated by the NSSA ABR to 0.0.0.0.
- If there are multiple ABRs in an NSSA, the system automatically selects an ABR as the translator according to certain rules (generally, the device with the largest router ID is selected in the NSSA) to translate Type 7 LSAs into Type 5 LSAs. You can configure the **translator-always** parameter on an ABR to specify the ABR as an all-the-time translator. To allow two ABRs to participate in load balancing, configure **translator-always** on the ABRs. You can use this command to pre-configure a fixed translator to prevent LSA flooding caused by translator role changes.
- To ensure service continuity during translator switching, specify the **translator-interval** parameter. The value of *interval-value* must be greater than the flooding interval.
- The **zero-address-forwarding** parameter is used to set the FA of the generated NSSA LSAs to 0.0.0.0 when external routes are imported to the ABR in an NSSA.

Step 5 (Optional) Run **default-cost cost**

The cost of the default route corresponding to Type 3 LSAs that are transmitted by the ABR to the NSSA is set.

To ensure the reachability of AS external routes, the ABR in the NSSA generates a default route and advertises it to other routers in the NSSA. Setting the cost helps control route selection.

Step 6 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

Run either of the following commands to check LSDB information:

- **display ospf [process-id] lsdb [brief]**
- **display ospf [process-id] lsdb [router | network | summary | asbr | ase | nssa | opaque-link | opaque-area] [link-state-id] [originate-router [advertising-router-id] | self-originate]**

Run either of the following commands to check routing table information:

- **display ospf [process-id] routing [ip-address [mask | mask-length]] [interface interface-type interface-number] [nexthop nexthop-address]**
- **display ospf [process-id] routing router-id [router-id]**

Run the **display ospf [process-id] interface [all | no-peer | interface-type interface-number] [verbose]** command to check OSPF interface information.

By comparing the OSPF routing tables before and after an NSSA is configured, you can reach the following conclusions:

- After an area is configured as an NSSA, the number of entries in the routing table is reduced.
- Different from a stub area, an NSSA can import AS external routes.

1.1.4.2.16 Configuring OSPF Local MT

On a network where multicast and an MPLS TE tunnel are deployed, you can configure OSPF local MT to create a correct multicast routing table and guide multicast packet forwarding.

Usage Scenario

When multicast and an Interior Gateway Protocol (IGP) Shortcut-enabled MPLS TE tunnel are configured on a network, the outbound interface of the route calculated by an IGP may not be a physical interface but a TE tunnel interface. Based on a unicast route to a multicast source address, the router sends a Join message through a TE tunnel interface. In this case, devices spanned by the TE tunnel cannot detect the Join message so that they do not create any multicast forwarding entry.

To resolve this problem, enable OSPF local MT. After local MT is enabled, if the outbound interface of a calculated route is an IGP Shortcut-enabled TE tunnel interface, the route management (RM) module creates an independent Multicast IGP (MIGP) routing table for the multicast protocol, calculates a physical outbound interface for the route, and adds the route to the MIGP routing table. Multicast packets are then forwarded along this route.

Configuring filtering policies for local MT controls the number of entries in the MIGP routing table and speeds up the MIGP routing table lookup.

Pre-configuration Tasks

Before configuring local MT, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring Devices are reachable at the network layer.
- **Configure basic OSPF functions.**
- Configure the IGP Shortcut.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **local-mt enable**

Local MT is enabled.

 NOTE

- Local MT takes effect only in the OSPF process of a public network instance.
- Local MT does not support Forwarding Adjacency (FA).

Step 4 (Optional) Run any of the following commands as required:

- Based on the basic ACL:
 - a. Run **local-mt filter-policy acl { acl-number | acl-name }**
A filtering policy is configured for OSPF local MT.
 - b. Run **quit**
Return to the system view.
 - c. Run **acl { name basic-acl-name { basic | [basic] number basic-acl-number } | [number] basic-acl-number } [match-order { config | auto }]**
The ACL view is displayed.
 - d. Run **rule [rule-id] [name rule-name] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name] ***
An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:

If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID

in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

- Based on an IP prefix list:
Run **local-mt filter-policy ip-prefix ip-prefix-name**
A routing policy is configured for OSPF local MT.
- Based on a route-policy:
Run **local-mt filter-policy route-policy route-policy-name**
A route-policy is configured for OSPF local MT.
- Based on a route-filter:
Run **local-mt filter-policy route-filter route-filter-name**
A route-filter is configured for OSPF local MT.

After an MIGP routing table is created, OSPF performs route calculation. If the outbound interface of the calculated route is an IGP Shortcut-enabled TE tunnel interface, the router saves the physical interface on which the tunnel interface is configured as the outbound interface in the MIGP routing table. Multicast packets are then forwarded along this route.

After the routing policy is configured, only the matching routes to the multicast source address are added to the MIGP routing table, which controls the number of entries in the MIGP routing table and speeds up MIGP routing table lookup.

Configure a routing policy before you enable local MT, because if an excessive number of routes to a non-multicast source address exist in an MIGP routing table, the number of entries may exceed the upper limit.

Step 5 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

- Run the **display ospf [process-id] migp-routing [ip-address [mask | mask-length]] [interface interface-type interface-number] [nexthop nexthop-address]** command to check MIGP routing table information.
- Run the **display ospf [process-id] routing** command to check OSPF routing table information.
- Run the **display ospf [process-id] brief** command to check brief OSPF information.

1.1.4.2.17 Configuring an OSPF Sham Link

This section describes how to configure an OSPF sham link so that traffic between sites of the same VPN in the same OSPF area is forwarded through the OSPF intra-area route over the BGP/MPLS IP VPN backbone network.

Usage Scenario

Generally, BGP peers use BGP extended community attributes to carry routing information over the BGP/MPLS IP VPN backbone network. PEs can use the

routing information to exchange inter-area routes between PEs and CEs through OSPF. OSPF sham links are unnumbered P2P links between two PEs over an MPLS VPN backbone network. The source and destination IP addresses of each sham link are IP addresses with a 32-bit mask of loopback interfaces. The loopback interfaces must be bound to a VPN instance, and routes of the two IP addresses are advertised through BGP.

On the BGP/MPLS IP VPN backbone network, if an intra-area OSPF link exists between the network segment where the local CE resides and the network segment where the remote CE resides, the route over this intra-area OSPF link is an intra-area route and has a higher priority than the inter-area route over the BGP/MPLS IP VPN backbone network. In this case, VPN traffic is always forwarded through this intra-area route. To prevent this problem, you can set up an OSPF sham link between the PEs so that the route over the MPLS IP VPN backbone network becomes an OSPF intra-area route and ensure that this route is preferentially selected.

Pre-configuration Tasks

Before configuring an OSPF sham link, complete the following tasks:

- Configure basic BGP/MPLS IP VPN functions and configure OSPF between each PE and its corresponding CE.
- Configure OSPF in the LAN of each CE.

Procedure

Step 1 Configure endpoint IP addresses for a sham link.

Perform the following steps on PEs at both ends of the sham link:

1. Run **system-view**

The system view is displayed.

2. Run **interface loopback *loopback-number***

A loopback interface is created, and its view is displayed.

Each VPN instance must have an endpoint IP address of a sham link, and the IP address is a loopback interface IP address with a 32-bit mask in the VPN address space of a PE. Sham links of the same OSPF process can share the same endpoint IP address. The endpoint IP addresses of sham links of different OSPF processes must be different.

3. Run **ip binding vpn-instance *vpn-instance-name***

A VPN instance is bound to the loopback interface.

4. Run **ip address *ip-address* { *mask* | *mask-length* }**

An IP address is configured for the loopback interface.

 **NOTE**

The configured IP address must have a 32-bit mask (255.255.255.255).

5. Run **commit**

The configuration is committed.

6. Run **quit**

Return to the system view.

Step 2 Advertise routes of the sham link's endpoint IP addresses.

Perform the following steps on PEs at both ends of the sham link:

1. Run **bgp as-number**

The BGP view is displayed.

2. Run **ipv4-family vpn-instance vpn-instance-name**

The BGP-VPN instance IPv4 address family view is displayed.

3. Run **import-route direct**

Import direct routes (routes of the sham link's endpoint IP addresses in this case) to BGP.

Routes of the sham link's endpoint IP addresses are advertised as VPN IPv4 routes by BGP.

 **NOTE**

Ensure that routes of the sham link's endpoint IP addresses are not exchanged by PEs through the VPN OSPF process.

If routes of the sham link's endpoint IP addresses are exchanged by PEs through the VPN OSPF process, each PE has two routes to the other endpoint of the sham link. One of the routes is learned through the VPN OSPF process, and the other is learned through the MP-BGP connection. Because the OSPF route has a higher priority than the BGP route, the OSPF route is selected, causing a sham link establishment failure.

4. Run **commit**

The configuration is committed.

5. Run **quit**

Return to the BGP view.

6. Run **quit**

Return to the system view.

Step 3 Create an OSPF sham link.

Perform the following steps on PEs at both ends of the sham link:

1. Run **ospf [process-id] [router-id router-id | vpn-instance vpn-instance-name] ***

The OSPF multi-instance view is displayed.

2. Run **area area-id**

The OSPF area view is displayed.

3. Run **sham-link source-ip-address destination-ip-address [smart-discover | cost cost | hello hello-interval | dead dead-interval | retransmit retransmit-interval | trans-delay trans-delay-interval | [simple [plain plain-text | cipher cipher-text | cipher-text] | { md5 | hmac-md5 | hmac-sha256 } [key-id { plain plain-text | cipher cipher-text | cipher-text }] | authentication-null | keychain keychain-name]] ***

A sham link is created.

The authentication modes configured at the two ends must be the same. If packet authentication is configured, only the OSPF packets that pass the authentication are accepted; if the authentication fails, the OSPF neighbor relationship cannot be established.

 **NOTE**

To ensure that VPN traffic is forwarded over the MPLS backbone network, ensure that the cost of the sham link is smaller than that of the OSPF route used to forward the traffic over the user network when running the **sham-link** command. In most cases, you need to change the cost of the interfaces on the user network to ensure that the cost of the OSPF route used to forward the traffic over the user network is greater than that of the sham link.

----End

Checking the Configurations

After configuring the OSPF sham link, run the following commands to check the configurations.

- Run the **display ip routing-table vpn-instance *vpn-instance-name*** command on PEs to check the VPN routing table.
- Run the **display ip routing-table** command on CEs to check the routing table.
- Run the **tracert *host*** command on a CE to check the nodes through which data is forwarded to the remote end.
- Run the **display ospf process-id sham-link [area *area-id*]** command on PEs to check whether the sham link is established.
- Run the **display ospf routing** command on CEs to check OSPF routes.

1.1.4.2.18 Configuring BFD for OSPF

After BFD for OSPF is enabled, if a link fails, the router rapidly detects the failure, notifies the OSPF process or interface of the fault, and instructs OSPF to recalculate routes. This speeds up OSPF network convergence.

Usage Scenario

OSPF enables the router to periodically send Hello packets to a neighboring router for fault detection. Detecting a fault takes more than 1s. As voice, video, and other VOD services are widely used. These services are sensitive to packet loss and delays. When traffic is transmitted at gigabit rates, long-time fault detection will cause packet loss. This cannot meet high reliability requirements of the carrier-class network. BFD for OSPF was introduced to resolve this problem. After BFD for OSPF is configured in a specified process or on a specified interface, the link status can be rapidly detected and fault detection can be completed in milliseconds. This speeds up OSPF convergence when the link status changes.

Pre-configuration Tasks

Before configuring BFD for OSPF, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- **Configure basic OSPF functions.**

Configuring BFD Globally

On two devices that need to establish a BFD session with each other, you can configure BFD for all the interfaces in a certain OSPF process.

Context

Perform the following steps on the router that runs OSPF:

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **bfd**

BFD is enabled globally.

Step 3 Run **commit**

The configuration is committed.

----End

Configuring BFD for an OSPF Process

Configuring BFD for an OSPF process helps the system rapidly detect link states and speeds up OSPF convergence in the case of a link state change.

Context

After BFD is configured for an OSPF process, when detecting a link failure, BFD rapidly notifies the failure to routers on both ends of the link, triggering rapid OSPF convergence. When the OSPF neighbor relationship goes Down, the BFD session will be dynamically deleted.

Before configuring BFD for OSPF, enable BFD globally.

To configure BFD on all the interfaces in an OSPF process, perform the following operations on the routers at both ends of the link where a BFD session is to be set up:

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **bfd all-interfaces enable**

BFD is enabled for the OSPF process to create BFD sessions.

Step 4 (Optional) Run **bfd all-interfaces { min-rx-interval receive-interval | min-tx-interval transmit-interval | detect-multiplier multiplier-value | frr-binding }** *

BFD session parameters are modified.

You can skip this step. The default interval at which BFD packets are transmitted and the default detection multiplier are recommended.

The parameters are configured based on the network status and network reliability requirements. A short interval at which BFD packets are transmitted can be configured for a link that has a higher requirement for reliability. A long interval at which BFD packets are transmitted can be configured for a link that has a lower requirement for reliability.

NOTE

- Actual interval at which BFD packets are transmitted on the local router = Max { configured interval *transmit-interval* at which BFD packets are transmitted on the local router, configured interval *receive-interval* at which BFD packets are received on the peer router }
- Actual interval at which BFD packets are received on the local router = Max { configured interval *transmit-interval* at which BFD packets are transmitted on the peer router, configured interval *receive-interval* at which BFD packets are received on the local router }
- Actual time for detecting BFD packets = Actual interval at which BFD packets are received on the local router x Configured detection multiplier *multiplier-value* on the peer router

For example:

- On the local router, the configured interval at which BFD packets are transmitted is 200 ms; the configured interval at which BFD packets are received is 300 ms; the detection multiplier is 4.
- On the peer router, the configured interval at which BFD packets are transmitted is 100 ms; the interval at which BFD packets are received is 600 ms; the detection multiplier is 5.

Then:

- On the local router, the actual interval at which BFD packets are transmitted is 600 ms calculated by using the formula max {200 ms, 600 ms}; the interval at which BFD packets are received is 300 ms calculated by using the formula max {100 ms, 300 ms}; the detection period is 1500 ms calculated by multiplying 300 ms by 5.
- On the peer router, the actual interval at which BFD packets are transmitted is 300 ms calculated by using the formula max {100 ms, 300 ms}, the actual interval at which BFD packets are received is 600 ms calculated by using the formula max {200 ms, 600 ms}, and the detection period is 2400 ms calculated by multiplying 600 ms by 4.

Step 5 (Optional) Prevent an interface from dynamically creating a BFD session.

After BFD for OSPF is configured, all interfaces on which neighbor relationships are Full in the OSPF process will create BFD sessions. To prevent specific interfaces from being enabled with BFD, disable these interfaces from dynamically creating BFD sessions.

1. Run **quit**

Return to the system view.

2. Run **interface *interface-type interface-number***

The interface view is displayed.

3. Run **ospf bfd block**

An interface is prevented from dynamically creating a BFD session.

4. Run **quit**

Return to the system view.

5. Run **ospf [process-id]**

The OSPF view is displayed.

Step 6 (Optional) Run **bfd all-interfaces incr-cost { cost | max-reachable } [wtr <wtr-value>]**

The OSPF process is enabled to adjust the cost based on the BFD session status.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

Step 7 Run **commit**

The configuration is committed.

----End

(Optional) Configuring BFD for a Specified Interface

Configuring BFD for OSPF on a specified interface helps speed up OSPF convergence in the case of an interface failure.

Context

After BFD for OSPF is configured on a specified interface and the interface becomes faulty, the router rapidly detects the fault and instructs OSPF to recalculate routes. This speeds up OSPF convergence. When the OSPF neighbor relationship goes Down, the BFD session between OSPF neighbors is dynamically deleted.

Before configuring BFD for OSPF, enable BFD globally.

Perform the following steps on the router where a BFD session is to be established on a specified interface:

 **NOTE**

The interface can be a physical interface or a GRE tunnel interface. If BFD is enabled on a GRE tunnel interface, millisecond-level fault detection can be implemented for the GRE tunnel.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **bfd**

BFD is globally configured.

Step 3 Run **quit**

Return to the system view.

Step 4 Run **interface interface-type interface-number**

The interface view is displayed.

Step 5 Run **ospf bfd enable**

BFD for OSPF is configured, and the default parameter values are used to establish a BFD session.

If BFD is enabled globally and the neighbor relationships on the interface are in the Full state, OSPF creates a BFD session with default parameter values for the interface.

The **ospf bfd enable [per-link one-arm-echo]** command can be run only in the VLANIF interface view.

If BFD for OSPF is configured for an Eth-Trunk with multiple physical interfaces added in a VLAN and **per-link one-arm-echo** is not specified, the BFD session may go down even if only one of the physical interfaces goes down. As a result, the OSPF neighbor relationship also goes down. If **per-link one-arm-echo** is specified in this case, the BFD session goes down only if all the physical interfaces are down, which ensures that the OSPF neighbor relationship can be established normally.

 **NOTE**

The configuration of BFD for OSPF on an interface takes precedence over that in the OSPF process.

Step 6 (Optional) Run **ospf bfd { min-rx-interval receive-interval | min-tx-interval transmit-interval | detect-multiplier multiplier-value | frr-binding } ***

BFD session parameters are modified.

The default interval at which BFD packets are transmitted and the default detection multiplier are recommended. As such, this step can be skipped.

The parameters need to be configured based on network conditions and requirements on network reliability. A short transmission interval for BFD packets can be set for a link that requires higher reliability, and a long transmission interval can be configured for a link that requires lower reliability.

 NOTE

- Actual interval at which BFD packets are transmitted on the local device = Max { *transmit-interval* (interval at which BFD packets are transmitted) set on the local device, *receive-interval* (interval at which BFD packets are received) set on the peer device }
- Actual interval at which BFD packets are received on the local device = Max { *transmit-interval* (interval at which BFD packets are transmitted) set on the peer device, *receive-interval* (interval at which BFD packets are received) set on the local device }
- Actual period for BFD detection on the local device = Actual interval at which BFD packets are received on the local device x Detection multiplier specified by *multiplier-value* on the peer device

For example:

- On the local device, the interval at which BFD packets are transmitted is set to 200 ms, the interval at which BFD packets are received is set to 300 ms, and the detection multiplier is set to 4.
- On the peer device, the interval at which BFD packets are transmitted is set to 100 ms, the interval at which BFD packets are received is set to 600 ms, and the detection multiplier is set to 5.

Then:

- On the local device, the actual interval at which BFD packets are transmitted is 600 ms (calculated through Max { 200 ms, 600 ms }); the actual interval at which BFD packets are received is 300 ms (calculated through Max { 100 ms, 300 ms }); the actual detection period is 1500 ms (calculated through 300 ms x 5).
- On the peer device, the actual interval at which BFD packets are transmitted is 300 ms (calculated through Max { 100 ms, 300 ms }); the actual interval at which BFD packets are received is 600 ms (calculated through Max { 200 ms, 600 ms }); the actual detection period is 2400 ms (calculated through 600 ms x 4).

Step 7 (Optional) Run **ospf bfd incr-cost { cost | max-reachable } [wtr <wtr-value>]**

The OSPF interface is enabled to adjust the cost based on the BFD session status.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

Step 8 Run **commit**

The configuration is committed.

----End

Verifying the Configuration of BFD for OSPF

After BFD for OSPF is configured, you can check information about the BFD session.

Prerequisites

BFD for OSPF has been configured.

Procedure

- Run either of the following commands to check the BFD session:
 - **display ospf [process-id] bfd session interface-type interface-number [router-id]**
 - **display ospf [process-id] bfd session { router-id | all }**
- End

1.1.4.2.19 Configuring OSPF IP FRR

If a link fails, an OSPF IP FRR-capable device can fast switch traffic to a backup link, which protects traffic and improves OSPF network reliability.

Usage Scenario

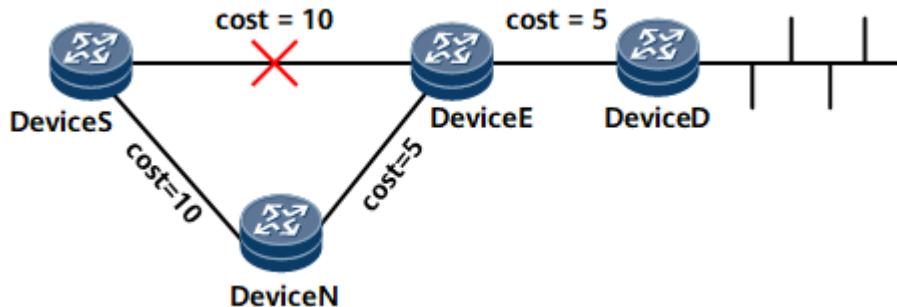

As networks develop, services such as Voice over IP (VoIP) and on-line video services require high-quality real-time transmission.

Nevertheless, if an OSPF fault occurs, traffic can be switched to a new link only after the fault detection that lasts several milliseconds, fault notification to the routing control plane that lasts several milliseconds, new topology information generation and flooding that last tens of milliseconds, Shortest Path First (SPF) calculation that lasts tens of milliseconds, and new route notification and adding that last hundreds of milliseconds. As a result, it takes much more than 50 ms, the maximum convergence time tolerable for VoIP and on-line video services, which cannot meet the requirement for real-time services on the network.

With OSPF IP FRR that calculates a backup link in advance, devices can fast switch traffic to the backup link without interrupting traffic if the primary link fails, which protects traffic and improves OSPF network reliability.

As shown in [Figure 1-122](#), traffic flows from Device S to Device D. The preceding inequality is met. Device S switches the traffic to the backup link if the primary link fails.

Figure 1-122 OSPF IP FRR link protection

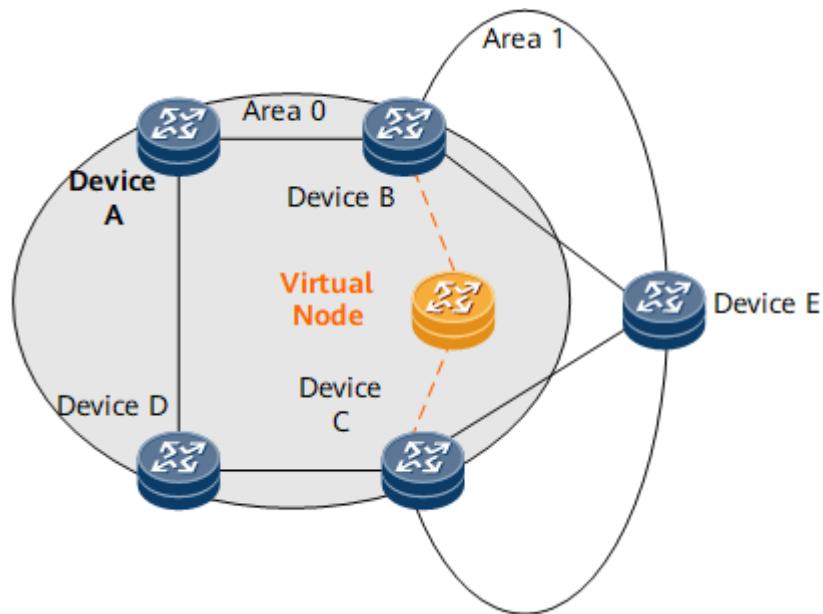

OSPF IP FRR is applicable to services that are sensitive to packet delay and packet loss.

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports OSPF IP FRR that uses LFA or Remote LFA as the algorithm.

LFA Auto FRR cannot be used to calculate alternate links on large-scale networks, especially on ring networks. To address this problem, enable Remote LFA Auto FRR. Remote LFA takes effect only when LFA has been enabled.

Both OSPF LFA FRR and OSPF remote LFA FRR use the SPF algorithm to calculate the shortest path to the destination node, with each neighbor that provides a backup link as the root node. The backup next hop is node-based, which applies to single-node routing scenarios. As networks are increasingly diversified, two ABRs or ASBRs are deployed to improve network reliability. In this case, OSPF FRR in a multi-node routing scenario is needed. In [Figure 1-123](#), Device B and Device C function as ABRs to forward area 0 and area 1 routes. Device E advertises an intra-area route. Upon receipt of the route, Device B and Device C translate it to a Type 3 LSA and flood the LSA to area 0. After OSPF FRR is enabled on Device A, Device A considers Device B and Device C as its neighbors. Without a fixed neighbor as the root node, Device A fails to calculate FRR backup next hop. To solve this problem, a virtual node is constructed between Device B and Device C. The virtual node converts the same route advertised by multiple nodes into a route with a single route source, and then calculates the backup next hop of the virtual node based on the LFA or Remote LFA algorithm. The same route advertised by multiple nodes inherits the backup next hop from the created virtual node.

Figure 1-123 OSPF FRR in the scenario where multiple nodes advertise the same route

After OSPF IP FRR is configured, the lower layer needs to fast respond to a link change so that traffic can be fast switched to the backup link. After FRR and BFD are bound, link failures can be detected rapidly so that traffic is rapidly switched to the backup link if the primary link fails.

Pre-configuration Tasks

Before configuring OSPF IP FRR, complete the following tasks:

- Configure a link layer protocol.

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- Configure basic OSPF functions.**
- Before you configure remote LFA FRR, configure LDP LSPs to perform recursion hop by hop between the source node and PQ node. That is, configure a local LDP session between each pair of directly connected nodes along the link from the source node to PQ node.

Enabling OSPF IP FRR

With OSPF IP FRR and loop-free backup links, a device can switch traffic to a backup link immediately if the primary link fails.

Context

Perform the following steps on the router:

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id | router-id router-id | vpn-instance vpn-instance-name]** *

An OSPF process is started, and the OSPF view is displayed.

Step 3 Run **frr**

The OSPF FRR view is displayed.

Step 4 Run **loop-free-alternate**

OSPF IP FRR is enabled to generate a loop-free backup link.

Step 5 (Optional) Run **frr-policy route { route-policy route-policy-name | route-filter route-filter-name }**

An OSPF IP FRR filtering policy is configured.

After the OSPF IP FRR filtering policy is configured, only the OSPF backup routes that match the filtering conditions of the policy can be added to the forwarding table.

Step 6 If you want to configure remote LFA OSPF IP FRR, perform the following steps:

- Run **remote-lfa tunnel ldp [maximum-reachable-cost cost-value]**

Remote LFA OSPF IP FRR is enabled.

- (Optional) Run **remote-lfa available-tunnel-destination ip-prefix ip-prefix-name**

A filtering policy is configured to filter PQ nodes.

After a filtering policy is configured, only the nodes that meet the filtering conditions become PQ nodes, which facilitates network optimization.

- Run **quit**

Return to the OSPF view.

4. (Optional) Run **avoid-microloop frr-protected**

The OSPF microloop avoidance is enabled.

5. (Optional) Run **avoid-microloop frr-protected rib-update-delay rib-update-delay**

The delay after which OSPF delivers routes is configured.

If OSPF remote LFA FRR is enabled and the primary link fails, traffic is switched to the backup link. If route convergence occurs again, traffic is switched from the backup link to a new primary link. During the switchover, microloop may occur. To prevent this problem, OSPF anti-microloop is enabled and delays the switching. To configure the delay, run the **avoid-microloop frr-protected rib-update-delay** command. After the command is run, OSPF does not switch traffic to the backup link until the delay elapses.

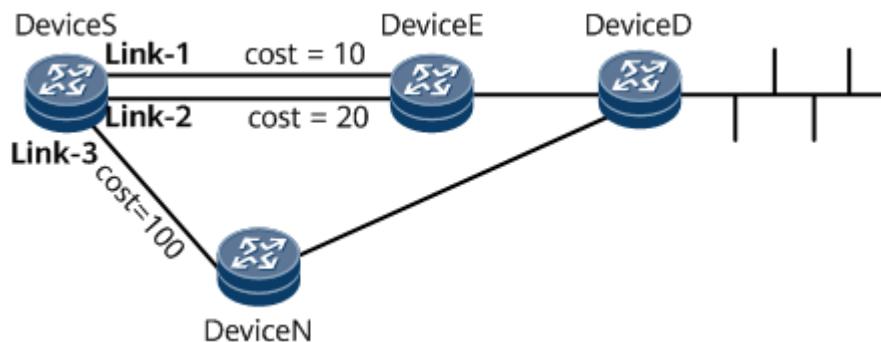

6. Run **frr**

The OSPF FRR view is displayed.

Step 7 (Optional) Run the **tiebreaker { node-protecting | lowest-cost | ldp-sync hold-max-cost | srlg-disjoint } preference** command to configure the solution of selecting a backup path for OSPF IP FRR.

By default, the solution of selecting a backup path for OSPF IP FRR is node-protection path first. In actual networking scenarios, the solution may need to be changed to smallest-cost path first due to considerations such as interface forwarding capacity and link cost. In [Figure 1-124](#), the primary path is Link-1 (DeviceS -> DeviceE -> DeviceD), and Link-2 and Link-3 (DeviceS -> DeviceN -> DeviceD) are backup path candidates. By default, Link-3 is selected as the backup path. To change the solution of selecting a backup path for OSPF IP FRR to smallest-cost path first, run the **tiebreaker** command. After the command is run, Link-2 is selected as the backup path.

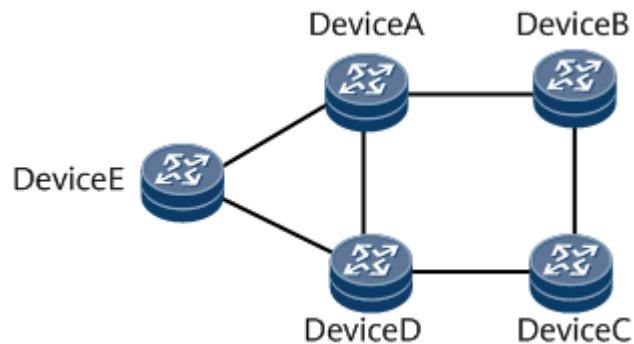

Figure 1-124 Solution of selecting a backup path for OSPF IP FRR

[Figure 1-125](#) shows an inter-board scenario, where Link-1 (Device A -> Device D) is the primary path, and Link-2 (Device A -> Device E -> Device D) is the backup path. After the primary path Link-1 fails, the primary path is switched to Link-2, and the backup path is Link-3 (Device A->Device B->Device C->Device D). If Link-1 goes Up again but the LDP session has not gone Up, OSPF enters the Hold-max-cost state. Consequently, the primary path is still Link-2, and the backup path is still Link-3. If the LDP session goes Up but **ldp-sync hold-max-cost** is not configured, OSPF exits from the Hold-max-cost state when the timer used to

delay sending an LDP session Up message expires. In this case, OSPF switches the primary path back to Link-1. Because the upstream and downstream entries reside on different boards and the downstream entry has not been updated when downstream traffic arrives, packet loss occurs. To resolve the problem, configure **ldp-sync hold-max-cost** so that OSPF preferentially selects the path with the maximum cost set by LDP-IGP synchronization when OSPF is in the Hold-max-cost state. The backup path is switched to Link-1, and backup forwarding entries are delivered in advance. When the timer used to delay sending an LDP session Up message expires, OSPF exits from the Hold-max-cost state and switches the primary path to Link-1. Because the downstream backup entry is available, no packet loss occurs.

Figure 1-125 Maximum-cost (set by LDP-IGP synchronization) path first solution

Step 8 Run commit

The configuration is committed.

----End

(Optional) Binding IP FRR and BFD

Binding IP FRR and BFD enables the lower layer to fast respond to a link change so that traffic can be rapidly switched to the backup link if the primary link fails.

Context

After the parameter **frr-binding** is set to bind the BFD status to the link status of an interface, link failures can be detected rapidly. This ensures that traffic is rapidly switched to the backup link if the primary link fails.

Perform the following steps on the router where IP FRR and BFD need to be bound:

Procedure

- Bind IP FRR and BFD in an OSPF process.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **ospf**
An OSPF process is started, and the OSPF view is displayed.

- c. Run **bfd all-interfaces frr-binding**
IP FRR and BFD are bound in the OSPF process.
 - d. Run **commit**
The configuration is committed.
- Bind IP FRR and BFD on a specified OSPF interface.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface interface-type interface-number**
The interface view is displayed.
 - c. Run **ospf bfd frr-binding**
IP FRR and BFD are bound on the interface.

 **NOTE**

The BFD configuration on an interface takes precedence over that in an OSPF process.

- d. Run **commit**
The configuration is committed.

----End

(Optional) Disabling OSPF IP FRR on an Interface

If an interface runs key services, ensure that the backup path does not pass through this interface so that services will not be affected after FRR calculation.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The view of an OSPF interface on which FRR is enabled is displayed.

Step 3 Run **ospf frr block**

FRR is blocked on the OSPF interface.

Step 4 (Optional) Run **ospf remote-lfa disable**

Interfaces of the specified level are disabled from being calculated as the Remote LFA next hop.

Step 5 Run **commit**

The configuration is committed.

----End

Verifying the Configuration of OSPF IP FRR

After configuring OSPF IP FRR, you can view the information about the backup next hop.

Prerequisites

OSPF IP FRR has been configured.

Procedure

- Run the **display ospf [process-id] routing** command to check the information about the primary and backup links after configuring OSPF IP FRR.

----End

1.1.4.2.20 Configuring OSPF GR Helper

To avoid traffic interruption and route flapping caused by the active/standby switchover, you can enable OSPF GR.

Usage Scenario

Graceful Restart (GR) is a technology that ensures normal data forwarding without affecting key services when a routing protocol restarts. GR is one of high availability (HA) technologies. HA technologies comprise a set of comprehensive techniques, such as fault-tolerant redundancy, link protection, faulty node recovery, and traffic engineering. As a fault-tolerant redundancy technology, GR is widely used to ensure non-stop forwarding of key data during the active/standby switchover and system upgrade.

GR involves two roles: the GR restarter and GR helper. The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports the GR helper only.

Pre-configuration Tasks

Before configuring OSPF GR, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- Configure basic OSPF functions.**

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **opaque-capability enable**

The Opaque-LSA capability is enabled.

OSPF supports OSPF GR through Type 9 LSAs. Therefore, before configuring GR, run the **opaque-capability enable** command to enable the Opaque-LSA capability.

Step 4 Configure GR session parameters on the helper.

1. Run **graceful-restart helper-role ignore-external-lsa**

The Helper is configured to ignore AS-external LSAs.

2. Run **graceful-restart helper-role planned-only**

The Helper is configured to support only planned GR.

3. Choose either of the following configuration as required:

- Based on a basic ACL:

- i. Run **graceful-restart [helper-role { { acl-number *acl-number* | acl-name *acl-name* } * } | never]**

GR session parameters on the helper are configured.

- ii. Run **quit**

The system view is displayed.

- iii. Run **acl { name *basic-acl-name* { basic | [basic] number *basic-acl-number* } | [number] *basic-acl-number* } [match-order { config | auto }]**

The ACL view is displayed.

- iv. Run **rule [rule-id] [name *rule-name*] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range *time-name* | vpn-instance *vpn-instance-name*] ***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

- Configure an IP prefix list.

- Run **graceful-restart [helper-role { { ip-prefix *ip-prefix-name* * } | never]**

GR session parameters on the helper are configured.

Step 5 Configure GR session parameters on the helper.

 **NOTE**

IETF mode and non-IETF mode are mutually exclusive.

- Configure GR session parameters on the helper in IETF mode.

- a. Run **graceful-restart helper-role ignore-external-lsa**

The helper does not check AS external LSAs.

- b. Run **graceful-restart helper-role planned-only**

The helper is configured to support only planned GR.

- c. Choose either of the following configuration as required:
- Based on a basic ACL:
 - 1) Run **graceful-restart [helper-role { { acl-number *acl-number* | acl-name *acl-name* }* } | never }**
GR session parameters on the helper are configured.
 - 2) Run **quit**
The system view is displayed.
 - 3) Run **acl { name *basic-acl-name* { basic | [basic] number *basic-acl-number* } | [number] *basic-acl-number* } [match-order { config | auto }]**
The ACL view is displayed.
 - 4) Run **rule [rule-id] [name *rule-name*] { deny | permit } [fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first }] | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range *time-name* | vpn-instance *vpn-instance-name*]***
The rule for the ACL is configured.
When the **rule** command is run to configure rules for a named ACL, only the source address range specified by **source** and the time period specified by **time-range** are valid as the rules.
 - Configure an IP prefix list.
Run **graceful-restart [helper-role { { ip-prefix *ip-prefix-name** } | never }]**
GR session parameters on the helper are configured.
 - Enable the non-IETF mode.
Run **graceful-restart non-ietf**
GR Helper in non-IETF mode is enabled.

Step 6 Run commit

The configuration is committed.

----End

Verifying the Configuration

Run the **display ospf graceful-restart** command, and you can view the configurations about OSPF GR.

1.1.4.2.21 Improving OSPF Network Security

On a network demanding high security, you can configure OSPF authentication and GTSM to improve OSPF network security.

Usage Scenario

With the increase in attacks on TCP/IP networks and the defects in the TCP/IP protocol suite, network attacks have increasing impacts on the network security.

Attacks on network devices may lead to network crash. Configuring OSPF authentication and GTSM can improve OSPF network security.

OSPF authentication encrypts OSPF packets by adding the authentication field to packets to ensure network security. When receiving an OSPF packet from a remote device, the local device discards the packet if the authentication password carried in the packet is different from the local one, protecting the local device against potential attacks.

In terms of the packet type, the authentication is classified as follows:

- Area authentication: configured in the OSPF area view and applies to packets on all interfaces in the OSPF area.
- Interface authentication: configured in the interface view and applies to all packets on the interface.

Pre-configuration Tasks

Before improving OSPF network security, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- **Configure basic OSPF functions.**
- Configure basic Keychain functions.

Configuring Area Authentication

OSPF supports packet authentication. With the authentication, only the packets that are authenticated are accepted; if packets fail to be authenticated, a neighbor relationship cannot be established. If area authentication is used, the authentication mode and password configurations on all the interfaces in the area must be identical.

Context

By default, no authentication mode is configured for an OSPF area. You are advised to configure an authentication mode to ensure system security.

For security purposes, you are advised not to use weak security algorithms in OSPF. If you need to use such an algorithm, run the **undo crypto weak-algorithm disable** command to enable the weak security algorithm function first.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id]**

The OSPF view is displayed.

Step 3 Run **area area-id**

The OSPF area view is displayed.

Step 4 Run any of the following commands to configure the authentication mode for the OSPF area as required:

- Run **authentication-mode simple [plain plain-text | [cipher] cipher-text]**
Simple authentication is configured for the OSPF area.
 - **plain** indicates the plaintext mode.
 - **cipher** indicates the ciphertext mode. For MD5, HMAC-MD5, or HMAC-SHA256 authentication, **cipher** is used by default.
- When configuring an authentication password, you are advised to use the ciphertext mode. If you select the plaintext mode, the password is saved in configuration files in plaintext, which poses a high security risk. To ensure device security, change the password periodically.
- Run **authentication-mode { md5 | hmac-md5 | hmac-sha256 } [key-id { plain plain-text | [cipher] cipher-text }]**
Cipher-text authentication is configured for the OSPF area.
 - **md5** indicates the MD5 ciphertext authentication mode.
 - **hmac-md5** indicates the HMAC-MD5 ciphertext authentication mode.
 - **hmac-sha256** indicates the HMAC-SHA256 ciphertext authentication mode.

 **NOTE**

For the sake of security, using the HMAC-SHA256 algorithm rather than the MD5 or HMAC-MD5 algorithm is recommended.

- Run **authentication-mode keychain Keychain-Name**
The Keychain authentication is configured for the OSPF area.

 **NOTE**

Before using the Keychain authentication, you must run the **keychain** command to create a keychain. Then, run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm for this keychain. Otherwise, the OSPF authentication will fail.

Step 5 Run **commit**

The configuration is committed.

----End

Configuring Interface Authentication

Interface authentication takes effect between neighboring devices' interfaces on which an authentication mode and password are configured. Interface authentication takes precedence over area authentication. Interfaces on the same network segment must have the same authentication mode and password. Interfaces on different network segments can have different authentication modes and passwords.

Context

NOTE

By default, no authentication mode is configured for an OSPF interface. You are advised to configure an authentication mode to ensure system security.

For security purposes, you are advised not to use weak security algorithms in OSPF. If you need to use such an algorithm, run the **undo crypto weak-algorithm disable** command to enable the weak security algorithm function first.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The OSPF interface view is displayed.

Step 3 Run any of the following commands to configure interface authentication as required:

- Run **ospf authentication-mode simple [plain plain-text | [cipher] cipher-text]**

Simple authentication is configured for the OSPF interface.

- **simple** indicates simple authentication.
- **plain** indicates the plaintext mode. In simple authentication mode, if this parameter is not specified, the **cipher** type is used by default.
- **cipher** indicates the ciphertext mode. For MD5, HMAC-MD5, or HMAC-SHA256 authentication, **cipher** is used by default.

When configuring an authentication password, you are advised to use the ciphertext mode. If you select the plaintext mode, the password is saved in configuration files in plaintext, which poses a high security risk. To ensure device security, change the password periodically.

- Run **ospf authentication-mode { md5 | hmac-md5 | hmac-sha256 } [key-id { plain plain-text | [cipher] cipher-text }]**

Ciphertext authentication is configured for the OSPF interface.

- **md5** indicates the MD5 ciphertext authentication mode.
- **hmac-md5** indicates the HMAC-MD5 ciphertext authentication mode.
- **hmac-sha256** indicates the HMAC-SHA256 ciphertext authentication mode.

NOTE

For the sake of security, using the HMAC-SHA256 algorithm rather than the MD5 or HMAC-MD5 algorithm is recommended.

- Run **ospf authentication-mode keychain keychain-name**

The Keychain authentication is configured for the OSPF interface.

 NOTE

Before using keychain authentication, run the **keychain** command to create a keychain. Then, run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm, respectively, for this keychain. If a keychain or its parameters are not configured, the OSPF authentication will fail.

- Run **ospf authentication-mode null**

The OSPF interface does not perform authentication.

Step 4 Run **commit**

The configuration is committed.

----End

Verifying the Configuration of OSPF Network Security

After configuring OSPF functions to improve OSPF network security, check the configuration.

Prerequisites

OSPF functions have been configured to improve OSPF network security.

Procedure

- Run the **display this** command to view the configurations of the system in the current view.

----End

1.1.4.2.22 Configuring the Network Management Function of OSPF

OSPF supports the network management function. You can bind the OSPF MIB to an OSPF process and configure trap and log functions.

Usage Scenario

Through the Simple Network Management Protocol (SNMP), the OSPF Management Information Base (MIB) manages information exchanged between the NMS and agents.

Pre-configuration Tasks

Before configuring the network management function of OSPF, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPF functions](#).

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf mib-binding process-id**

The OSPF process is bound to the MIB.

Step 3 Run **commit**

The configuration is committed.

----End

Checking the Configurations

Run the following commands to check the previous configuration.

Run the **display ospf [process-id] brief** command to view information about the binding of OSPF MIBs and OSPF processes.

1.1.4.2.23 Configuring Whitelist Session-CAR for OSPF

You can configure whitelist session-CAR for OSPF to isolate bandwidth resources by session for OSPF packets. This configuration prevents bandwidth preemption among OSPF sessions in the case of a traffic burst.

Context

When OSPF packets suffer a traffic burst, bandwidth may be preempted among OSPF sessions. To resolve this problem, you can configure whitelist session-CAR for OSPF to isolate bandwidth resources by session. If the default parameters of whitelist session-CAR for OSPF do not meet service requirements, you can adjust them as required.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **whitelist session-car ospf { cir cir-value | cbs cbs-value | pir pir-value | pbs pbs-value } ***

Parameters of whitelist session-CAR for OSPF are configured.

In normal cases, you are advised to use the default values of these parameters.

Step 3 (Optional) Run **whitelist session-car ospf disable**

Whitelist session-CAR for OSPF is disabled.

By default, whitelist session-CAR for OSPF is enabled. In normal cases, you are advised to keep this function enabled. Disable it if it becomes abnormal or adversely affects other services.

Step 4 Run **commit**

The configuration is committed.

----End

Verifying the Configuration

After configuring whitelist session-CAR for OSPF, verify the configuration.

- Run the **display cpu-defend whitelist session-car ospf statistics slot slot-id** command to check statistics about whitelist session-CAR for OSPF on a specified interface board.

1.1.4.2.24 Configuring Micro-Isolation CAR for OSPF

By default, micro-isolation CAR is enabled for OSPF, implementing micro-isolation protection for OSPF packets based on interfaces and destination IP addresses to protect session establishment.

Context

By default, micro-isolation CAR is enabled for OSPF, implementing micro-isolation protection for OSPF packets based on interfaces and destination IP addresses to protect session establishment. When OSPF packets encounter a traffic burst, a large number of OSPF packets may preempt interface bandwidth resources. In the case of an attack, a large number of invalid packets sent to other IP addresses may preempt the bandwidth. Therefore, you are advised not to disable this function.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **micro-isolation protocol-car ospf { cir cir-value | cbs cbs-value | pir pir-value | pbs pbs-value } ***

Micro-isolation CAR parameters are configured for OSPF.

In normal cases, you are advised to use the default values of these parameters. *pir-value* must be greater than or equal to *cir-value*, and *pbs-value* must be greater than or equal to *cbs-value*.

Step 3 (Optional) Run **micro-isolation protocol-car ospf disable**

Micro-isolation CAR is disabled for OSPF.

By default, micro-isolation CAR for OSPF is enabled. To disable this function, run the **micro-isolation protocol-car ospf disable** command. If this function is disabled, micro-isolation protection is no longer implemented for OSPF packets based on interfaces and destination IP addresses. In normal cases, you are advised to keep micro-isolation CAR enabled for OSPF.

Step 4 Run **commit**

The configuration is committed.

----End

1.1.4.2.25 Configuring the Threshold Alarm Function for the Number of OSPF Neighbors

If the alarm function is configured for the number of OSPF neighbors and the number of OSPF neighbors exceeds the threshold, an alarm is generated.

Context

When the number of established OSPF neighbor relationships exceeds the specifications of the device, establishing more OSPF neighbor relationships may cause the neighbor status to be unstable. To prevent this problem, you can enable the alarm function for the number of OSPF neighbor relationships so that an alarm is generated when the number of OSPF neighbor relationships exceeds the upper alarm threshold.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf peer alarm-threshold *threshold-value upper-limit upper-value lower-limit lower-value***

The threshold alarm function is configured for the number of OSPF neighbors.

Step 3 Run **commit**

The configuration is committed.

----End

1.1.4.2.26 Maintaining OSPF

Maintaining OSPF involves resetting OSPF and clearing OSPF statistics.

Clearing OSPF Statistics

This section describes how to clear OSPF statistics, including statistics about OSPF counters and statistics about session-CAR.

Context

NOTICE

OSPF information cannot be restored after you clear it. Exercise caution when clearing it.

To clear OSPF information, run the following reset commands in the user view.

Procedure

- Run the **reset ospf [*process-id*] counters [**neighbor** [*interface-type interface-number*] [*router-id*]]** command to reset OSPF counters.

- **counters** indicates OSPF counters.
- **neighbor** indicates neighbor information on the specified interface.
- Run the **reset ospf [process-id] counters maxage-lsa** command to delete the statistics about router LSAs that have reached the aging time.
- Run the **reset ospf [process-id] frr** command to perform OSPF IP FRR calculation again.
- Run the **reset ospf [process-id] peer [interface-type interface-number] router-id** command to restart an OSPF neighbor.
- Run the **reset cpu-defend whitelist session-car ospf statistics slot slot-id** command to clear statistics about whitelist session-CAR for OSPF on a specified interface board.

----End

Resetting OSPF

You can reset OSPF by restarting OSPF.

Context

NOTICE

Resetting an OSPF connection interrupts the OSPF adjacency between devices. Exercise caution when running the command.

To reset OSPF connections, perform the following operation:

Procedure

- Run the **reset ospf [process-id] process** command to restart the OSPF process.

After the **reset ospf process** command is used to restart OSPF, the following situations may occur:
 - If the router ID is changed, the new router ID takes affect after the **reset ospf process** command is run.
 - The DR and BDR are re-selected after the **reset ospf process** command is run.
- Run the **reset ospf [process-id] spf** to recalculate OSPF routes.
- Run the **reset ospf [process-id] redistribution** to reset OSPF route redistribution.

----End

Disabling OSPF Memory Overload Control

The OSPF memory overload control function is enabled by default. You can disable this function if necessary.

Context

By default, OSPF memory overload control is enabled. When the system memory is overloaded, each module needs to take necessary measures to control the memory usage. Upon receiving a memory overload notification from the system, the OSPF module no longer imports new routes and starts to control neighbor relationship establishment based on the memory overload condition to enhance OSPF resilience. In this case, new neighbor relationships cannot be established. For existing neighbor relationships, if they are in the Full state, they will be retained; if they are in a non-Full state, they are not reestablished until the memory recovers from overload.

Procedure

- Step 1** Run the **system-view** command to enter the system view.
- Step 2** Run the **ospf memory-overload control disable** command to disable OSPF memory overload control.

 NOTE

To reduce the impact of memory overload on services, you are advised not to disable OSPF memory overload control.

- Step 3** Run the **commit** command to commit the configuration.

----End

Disabling OSPF CPU Overload Control

The OSPF CPU overload control function is enabled by default. You can disable this function if necessary.

Context

By default, OSPF CPU overload control is enabled. If a device's CPU is overloaded, each module takes necessary measures to control its own CPU usage accordingly. Upon receiving a CPU overload notification from the system, the OSPF module controls the speeds of some internal computing processes and the establishment of neighbor relationships based on the CPU overload condition to enhance the resilience of OSPF. In this case, new neighbor relationships cannot be established. For original neighbor relationships, if a neighbor relationship is in the Full state, it will be retained; if a neighbor relationship is in a non-Full state, establishment of the neighbor relationship is paused and can continue only after the CPU recovers from overload.

Procedure

- Step 1** Run **system-view**

The system view is displayed.

- Step 2** Run **ospf cpu-overload control disable**

OSPF CPU overload control is disabled.

 NOTE

To minimize the impact of CPU overload upon services, you are advised not to disable OSPF CPU overload control.

Step 3 Run commit

The configuration is committed.

----End

1.1.4.2.27 Configuring OSPF Multi-Area Adjacency

OSPF multi-area adjacency allows one link to be shared by multiple OSPF areas.

Usage Scenario

According to OSPF, intra-area paths take precedence over inter-area paths. If a link in an area is a high-speed link, routes in other areas cannot use the high-speed link for transmission at the same time. Instead, they can use only low-speed links. To solve this problem, run the **ospf enable multi-area** command to enable OSPF on the multi-area adjacency interface so that a path can be shared by multiple areas.

Among the OSPF features supported by an OSPF multi-area adjacency interface, some can be inherited from the main interface, whereas others need to be configured independently. For details, see [Table 1-50](#).

Table 1-50 OSPF features supported by OSPF multi-area adjacency interfaces

OSPF Feature	Description	Related Configuration Links
BFD for OSPF	BFD for OSPF can be inherited from main interfaces, except for the configuration that disables BFD from an interface. This configuration needs to be configured independently.	Disabling an OSPF Multi-Area Adjacency Interface from Creating BFD Sessions
OSPF fast convergence	OSPF multi-area adjacency interfaces support OSPF fast convergence which needs to be configured independently for these interfaces and cannot be inherited from their main interfaces.	Configuring Fast Convergence for a Multi-Area Adjacency Interface

OSPF Feature	Description	Related Configuration Links
IGP-LDP synchronization	OSPF multi-area adjacency interfaces support IGP-LDP synchronization which needs to be configured independently for these interfaces and cannot be inherited from their main interfaces.	Configuring LDP-IGP Synchronization
OSPF IP FRR	OSPF multi-area adjacency interfaces support OSPF IP FRR. OSPF IP FRR can be inherited from main interfaces, except for the configuration that disables FRR from a specified OSPF interface. This configuration needs to be configured independently for OSPF multi-area adjacency interfaces.	Disabling OSPF IP FRR on an OSPF Multi-Area Adjacency Interface
OSPF neighbor relationship flapping suppression	OSPF multi-area adjacency interfaces support OSPF neighbor relationship flapping suppression which needs to be configured independently for these interfaces and cannot be inherited from their main interfaces.	Configuring Neighbor Relationship Flapping Suppression on an OSPF Multi-Area Adjacency Interface
OSPF flush LSA source tracing	OSPF multi-area adjacency interfaces support OSPF flush LSA source tracing which can be inherited from their main interfaces.	1.1.4.2.12 Configuring OSPF Flush Source Tracing
OSPF TE	OSPF multi-area adjacency interfaces inherit TE information from their main interfaces.	Configuring IGP TE (OSPF or IS-IS)

Pre-configuration Tasks

Before configuring OSPF multi-area adjacency, complete the following tasks:

- Configure a link layer protocol.
- Assign an IP address to each interface to ensure reachability between neighboring nodes at the network layer.
- [Configure basic OSPF functions.](#)

Enabling OSPF on a Multi-Area Adjacency Interface

Enabling OSPF on a multi-area adjacency interface is the prerequisite for configuring basic multi-area adjacency functions.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **ospf [process-id | router-id router-id] ***

An OSPF process is started, and the OSPF view is displayed.

Step 3 Run **area area-id**

The OSPF area view is displayed.

Step 4 Enable OSPF on an interface.

1. Run twice **quit**

The system view is displayed.

2. Run **interface interface-type interface-number**

The interface view is displayed.

3. Run **ospf enable [process-id] area area-id**

OSPF is enabled on the interface.

Step 5 Run **ospf enable multi-area area-id**

OSPF is enabled on the multi-area adjacency interface.

Step 6 Run **ospf mtu-enable multi-area area-id**

The multi-area adjacency interface is configured to fill in DD packets with the MTU value when sending the packets and check whether the MTU in each DD packet received from a neighbor exceeds the MTU of the local interface.

NOTICE

Enabling an interface to fill in DD Packets with its MTU will cause the involved neighbor relationship to be re-established.

Step 7 Run **commit**

The configuration is committed.

----End

Configuring a Cost for a Multi-Area Adjacency Interface

Configuring a cost for a multi-area adjacency interface can control route selection.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run interface *interface-type interface-number*

The interface view is displayed.

Step 3 Run ospf enable [*process-id*] area *area-id*

OSPF is enabled on the interface.

Step 4 Run ospf enable multi-area *area-id*

OSPF is enabled on the multi-area adjacency interface.

Step 5 Run ospf cost *cost* multi-area *area-id*

A cost is configured for the multi-area adjacency interface.

Step 6 Run commit

The configuration is committed.

----End

Configuring an Authentication Mode for a Multi-Area Adjacency Interface

Configuring an authentication mode for a multi-area adjacency interface improves OSPF network security.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run interface *interface-type interface-number*

The interface view is displayed.

Step 3 Run ospf enable [*process-id*] area *area-id*

OSPF is enabled on the interface.

Step 4 Run ospf enable multi-area *area-id*

OSPF is enabled on the multi-area adjacency interface.

Step 5 Run either of the following commands:

- Run the **ospf authentication-mode simple [plain *plain-text* | [cipher] *cipher-text*] multi-area *area-id*** command to configure simple authentication for the multi-area adjacency interface.
- Run the **ospf authentication-mode { md5 | hmac-md5 | hmac-sha256 } [key-id { plain *plain-text* | [cipher] *cipher-text* }] multi-area *area-id*** command to configure ciphertext authentication for the multi-area adjacency interface.

- Run the **ospf authentication-mode keychain *keychain-name multi-area area-id*** command to configure keychain authentication for the multi-area adjacency interface.
- Run the **ospf authentication-mode null multi-area *area-id*** command to configure null authentication for the multi-area adjacency interface.

Step 6 Run **commit**

The configuration is committed.

----End

Configuring Fast Convergence for a Multi-Area Adjacency Interface

Configuring fast convergence for a multi-area adjacency interface improves network performance.

Procedure

- Configure the interval at which a multi-area adjacency interface sends Hello packets.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface *interface-type interface-number***
The OSPF interface view is displayed.
 - c. Run **ospf enable [*process-id*] area *area-id***
OSPF is enabled on the interface.
 - d. Run **ospf enable multi-area *area-id***
OSPF is enabled on the multi-area adjacency interface.
 - e. Run **ospf timer hello *interval multi-area area-id***
The interval at which Hello packets are sent is configured on the multi-area adjacency interface.
 - f. Run **commit**
The configuration is committed.
- Configure the dead interval of OSPF neighbor relationships for a multi-area adjacency interface.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface *interface-type interface-number***
The OSPF interface view is displayed.
 - c. Run **ospf enable [*process-id*] area *area-id***
OSPF is enabled on the interface.
 - d. Run **ospf enable multi-area *area-id***
OSPF is enabled on the multi-area adjacency interface.

- e. Run **ospf timer dead** *interval multi-area area-id*
The dead interval of OSPF neighbor relationships is configured for the multi-area adjacency interface.
- f. Run **commit**
The configuration is committed.
- Configure an LSA retransmission interval on a multi-area adjacency interface.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface** *interface-type interface-number*
The OSPF interface view is displayed.
 - c. Run **ospf enable** [*process-id*] **area** *area-id*
OSPF is enabled on the interface.
 - d. Run **ospf enable multi-area** *area-id*
OSPF is enabled on the multi-area adjacency interface.
 - e. Run **ospf timer retransmit** *interval multi-area area-id*
An LSA retransmission interval is configured on the multi-area adjacency interface.
 - f. Run **commit**
The configuration is committed.
- Configure an LSA transmission delay on a multi-area adjacency interface.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface** *interface-type interface-number*
The OSPF interface view is displayed.
 - c. Run **ospf enable** [*process-id*] **area** *area-id*
OSPF is enabled on the interface.
 - d. Run **ospf enable multi-area** *area-id*
OSPF is enabled on the multi-area adjacency interface.
 - e. Run **ospf trans-delay** *interval multi-area area-id*
An LSA transmission delay is configured on the multi-area adjacency interface.
 - f. Run **commit**
The configuration is committed.
- Configure smart-discover on a multi-area adjacency interface.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface** *interface-type interface-number*
The OSPF interface view is displayed.

- c. Run **ospf enable [process-id] area area-id**
OSPF is enabled on the interface.
 - d. Run **ospf enable multi-area area-id**
OSPF is enabled on the multi-area adjacency interface.
 - e. Run **ospf smart-discover multi-area area-id**
Smart-discover is enabled on the multi-area adjacency interface.
Without smart-discover, if the neighbor status of a device on a P2P network changes or the DR or BDR on a multi-access network (broadcast or NBMA network) changes, Hello packets are not sent to neighbors until the Hello timer expires. This slows down the establishment of neighbor relationships. With smart-discover, Hello packets are sent to neighbors immediately in this case, regardless of the Hello timer. This speeds up neighbor relationship establishment and network convergence.
 - f. Run **commit**
The configuration is committed.
- Configure an OSPF multi-area adjacency interface to filter the LSAs to be sent.
 - a. Run **system-view**
The system view is displayed.
 - b. Run **interface interface-type interface-number**
The OSPF interface view is displayed.
 - c. Run **ospf enable [process-id] area area-id**
OSPF is enabled on the interface.
 - d. Run **ospf enable multi-area area-id**
OSPF is enabled on the multi-area adjacency interface.
 - e. Run **ospf filter-lsa-out { all | { summary [acl { acl-number| acl-name }] | ase [acl { acl-number| acl-name }] | nssa [acl { acl-number| acl-name }] } * } multi-area area-id**
The multi-area adjacency interface is configured to filter the LSAs to be sent.
If multiple links exist between two devices, you can configure the local device to filter the LSAs to be sent. This prevents unnecessary LSA transmission and reserves bandwidth resources.
 - f. Run **commit**
The configuration is committed.

----End

Configuring Neighbor Relationship Flapping Suppression on an OSPF Multi-Area Adjacency Interface

Neighbor relationship flapping suppression can be configured on an OSPF multi-area adjacency interface to delay OSPF neighbor relationship reestablishment or set the link cost to the maximum value in case of neighbor relationship flapping.

Usage Scenario

If an interface carrying OSPF services alternates between Up and Down, OSPF neighbor relationship flapping occurs on the interface. During the flapping, OSPF frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, OSPF services, and other OSPF-dependent services, such as LDP and BGP. OSPF neighbor relationship flapping suppression can address this problem by delaying OSPF neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

The following steps are optional, and choose them as required.

Procedure

Step 1 Run **system-view**

The system view is displayed.

To disable the function globally, run the **suppress-flapping peer disable** command.

Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

Step 3 Run **ospf enable [process-id] area area-id**

OSPF is enabled on the interface.

Step 4 Run **ospf enable multi-area area-id**

OSPF is enabled on the multi-area adjacency interface.

Step 5 (Optional) Run **ospf suppress-flapping peer disable multi-area area-id**

OSPF neighbor relationship flapping suppression on a multi-area adjacency interface is disabled.

To disable OSPF neighbor relationship flapping suppression from one of the interfaces, run this command.

Step 6 Run **ospf suppress-flapping peer hold-down interval multi-area area-id**

The Hold-down mode and its duration are configured for the multi-area adjacency interface.

OSPF neighbor relationship flapping suppression operates in Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationship reestablishment during the suppression period, which reduces LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use 65535 (maximum value) as the cost of the flapping link during the suppression period. This prevents traffic from passing through the flapping link.

 NOTE

To change the value of Max-cost for OSPF links, run the **maximum-link-cost cost** command.

The Hold-down mode and Hold-max-cost mode can be both used. When both modes are configured, the device first enters the Hold-down mode. After exiting the Hold-down mode, the device enters the Hold-max-cost mode.

To disable the Hold-max-cost mode, run the **ospf suppress-flapping peer hold-max-cost disable multi-area** command.

Step 7 Run **ospf suppress-flapping peer { detecting-interval *detecting-interval* | threshold *threshold* | resume-interval *resume-interval* } * multi-area *area-id***

Detection parameters are configured for OSPF neighbor relationship flapping suppression on the multi-area adjacency interface.

- Configure a threshold for exiting OSPF neighbor relationship flapping suppression.
If the interval between two successive neighbor relationship state changes from Full to a non-Full state is longer than the *resume-interval*, the flapping_count is reset.
- If OSPF neighbor relationship flapping suppression works in Hold-max-cost mode, the value of *resume-interval* indicates the duration of this mode.

 NOTE

The value of *resume-interval* must be greater than that of *detecting-interval*.

You can configure detection parameters for OSPF neighbor relationship flapping suppression on specific interfaces according to network conditions. However, using the default values of these parameters is recommended.

Step 8 Run **quit**

The system view is displayed.

Step 9 Run **quit**

The user view is displayed.

Step 10 Run **reset ospf suppress-flapping process-id peer [interface-name [all-areas | area *area-id*] | interface-type *interface-number* [all-areas | area*area-id*]] [notify-peer]**

The OSPF multi-area adjacency interface is configured to exit OSPF neighbor relationship flapping suppression.

 NOTE

The interface exits flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding OSPF process is reset.
- An OSPF neighbor is reset using the **reset ospf peer** command.
- OSPF neighbor relationship flapping suppression is disabled globally using the **suppress-flapping peer disable (OSPF)** command.
- The **reset ospf suppress-flapping peer** command is run.

Step 11 Run commit

The configuration is committed.

----End

Disabling an OSPF Multi-Area Adjacency Interface from Creating BFD Sessions

After BFD for OSPF is configured, all interfaces on which neighbor relationships are in Full state in the OSPF process create BFD sessions. You can disable an interface from creating BFD sessions as required.

Procedure

Step 1 Run system-view

The system view is displayed.

Step 2 Run `interface interface-type interface-number`

The interface view is displayed.

Step 3 Run `ospf enable [process-id] area area-id`

OSPF is enabled on the interface.

Step 4 Run `ospf enable multi-area area-id`

OSPF is enabled on the multi-area adjacency interface.

Step 5 Run `ospf bfd block multi-area area-id`

The OSPF multi-area adjacency interface is disabled from creating BFD sessions.

Step 6 Run commit

The configuration is committed.

----End

Disabling OSPF IP FRR on an OSPF Multi-Area Adjacency Interface

OSPF IP fast reroute (FRR) can be disabled on an OSPF multi-area adjacency interface that is connected to a link carrying key services. This prevents FRR from calculating the link as the backup link and minimizes any potential impact on the services.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

Step 3 Run **ospf enable [process-id] area area-id**

OSPF is enabled on the interface.

Step 4 Run **ospf enable multi-area area-id**

OSPF is enabled on the multi-area adjacency interface.

Step 5 Run **ospf frr block multi-area area-id**

OSPF IP FRR is disabled on the OSPF multi-area adjacency interface.

Step 6 (Optional) Run **ospf remote-lfa disable multi-area area-id**

Remote loop-free alternate (LFA) is disabled on the OSPF multi-area adjacency interface.

Step 7 Run **commit**

The configuration is committed.

----End

Configuring a Fallback Cost for an Eth-Trunk Multi-Area Adjacency Interface

Configuring a fallback cost for an Eth-Trunk multi-area adjacency interface helps control route selection.

Context

After an Eth-trunk member interface goes down, the OSPF cost value is automatically adjusted. When an Eth-trunk member interface becomes invalid, the remaining bandwidth may fail to meet user requirements, causing service loss. In this fault scenario, the cost of the Eth-Trunk can be dynamically adjusted to a larger value so that traffic is transmitted through other paths. When the interface bandwidth is less than the fallback bandwidth threshold, the device changes the interface cost to the configured fallback cost in time so that a better transmission path is selected. When the bandwidth of an Eth-Trunk interface is greater than or equal to the configured fallback bandwidth threshold, cost-fallback does not take effect.

Procedure

Step 1 Run **system-view**

The system view is displayed.

Step 2 Run **interface eth-trunk trunk-id**

The Eth-Trunk interface view is displayed.

Step 3 Run **ospf enable [process-id] area area-id**

OSPF is enabled on the interface.

Step 4 Run **ospf enable multi-area area-id**

OSPF is enabled on the multi-area adjacency interface.

Step 5 Run **ospf cost-fallback fallbackcost threshold fallbackbw multi-area area-id**

A fallback cost is configured for an Eth-Trunk multi-area adjacency interface.

Step 6 Run **commit**

The configuration is committed.

----End

Maintaining OSPF on a Multi-Area Adjacency Interface

Context

NOTICE

OSPF statistics cannot be restored after being cleared. Therefore, exercise caution before clearing the OSPF statistics.

To clear OSPF statistics, run the following command in the user view.

Procedure

- Run **reset ospf [process-id] counters [neighbor [interface-type interface-number [all-areas | area area-id]] | [interface-name [all-areas | area area-id]] [router-id]]**

OSPF statistics are cleared.

----End

Verifying the Configuration of OSPF Multi-Area Adjacency

After configuring OSPF multi-area adjacency, verify the configuration.

Prerequisites

OSPF multi-area adjacency has been configured.

Procedure

- Run the following commands and check **(M) Indicates MADJ interface**, **Multi-area interface**, and **Multi-area Interface Count** fields to view configurations on the multi-area adjacency interface:
 - display ospf brief**
 - display ospf interface**

– display ospf peer
----End

1.1.4.2.28 Configuration Examples for OSPF

This section provides several OSPF configuration examples.

Example for Configuring Basic OSPF Functions

This section describes how to configure basic OSPF functions, including enabling OSPF on each router and specifying network segments in different areas.

Networking Requirements

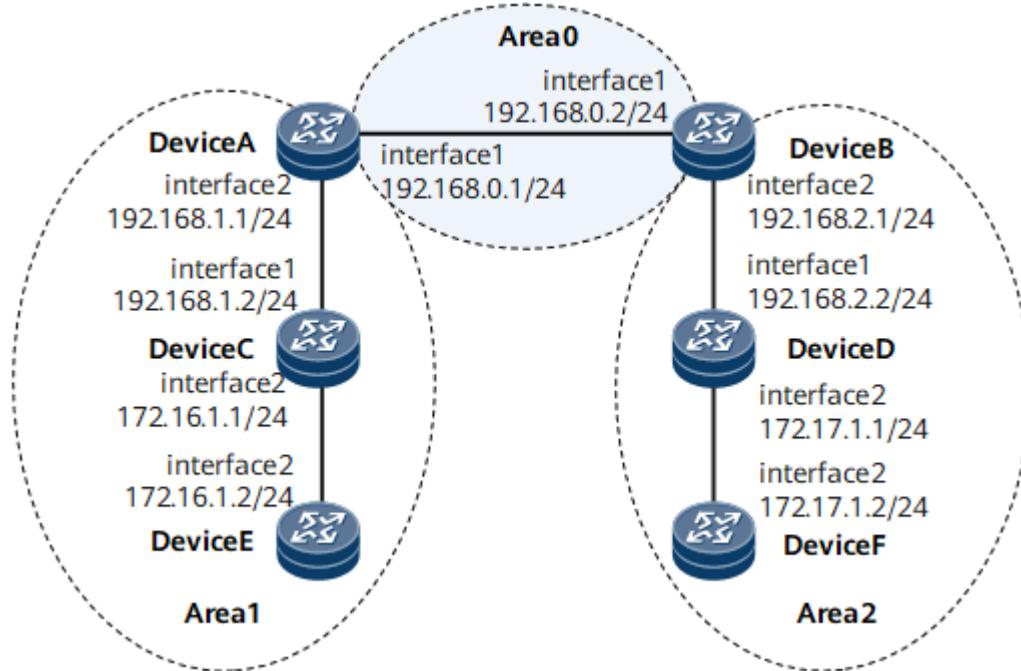

On the network shown in [Figure 1-126](#), all routers run OSPF, and the entire AS is divided into three areas. DeviceA and DeviceB function as ABRs to forward inter-area routes.

After the configuration is complete, each router should learn the routes to all network segments in the AS.

Figure 1-126 Networking for configuring basic OSPF functions

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

Precautions

When configuring basic OSPF functions, note the following rules:

- The backbone area is responsible for forwarding inter-area routes. In addition, the routing information between non-backbone areas must be forwarded through the backbone area. OSPF defines the following rules for the backbone area:
 - Connectivity must be available between non-backbone areas and the backbone area.
 - Connectivity must be available over the backbone area.
- The intervals at which Hello, Dead, and Poll packets are sent on the local interface must be the same as those on the remote interface. Otherwise, the OSPF neighbor relationship cannot be established.

Configuration Roadmap

The configuration roadmap is as follows:

1. Enable OSPF on each router.
2. Specify network segments in different areas.
3. Configure ciphertext authentication for the OSPF area.

Data Preparation

To complete the configuration, you need the following data:

Device Name	Router ID	Process ID	IP Address
Device A	1.1.1.1	1	Area 0: 192.168.0.0/24 Area 1: 192.168.1.0/24
Device B	2.2.2.2	1	Area 0: 192.168.0.0/24 Area 2: 192.168.2.0/24
Device C	3.3.3.3	1	Area 1: 192.168.1.0/24 and 172.16.1.0/24
Device D	4.4.4.4	1	Area 2: 192.168.2.0/24 and 172.17.1.0/24
Device E	5.5.5.5	1	Area 1: 172.16.1.0/24

Device F	6.6.6.6	1	Area 2: 172.17.1.0/24
----------	---------	---	--------------------------

Procedure

Step 1 Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure basic OSPF functions.

Configure DeviceA.

```
[~DeviceA] router id 1.1.1.1
[*DeviceA] ospf 1
[*DeviceA-ospf-1] area 0
[*DeviceA-ospf-1-area-0.0.0] network 192.168.0.0 0.0.0.255
[*DeviceA-ospf-1-area-0.0.0] quit
[*DeviceA-ospf-1] area 1
[*DeviceA-ospf-1-area-0.0.1] network 192.168.1.0 0.0.0.255
[*DeviceA-ospf-1-area-0.0.1] quit
[*DeviceA-ospf-1] commit
```

Configure DeviceB.

```
[~DeviceB] router id 2.2.2.2
[*DeviceB] ospf 1
[*DeviceB-ospf-1] area 0
[*DeviceB-ospf-1-area-0.0.0] network 192.168.0.0 0.0.0.255
[*DeviceB-ospf-1-area-0.0.0] quit
[*DeviceB-ospf-1] area 2

[*DeviceE-ospf-1-area-0.0.1] commit
[~DeviceE-ospf-1-area-0.0.1] quit
```

Configure DeviceF.

```
[~DeviceF] router id 6.6.6.6
```

```
[~DeviceF] ospf 1
[*DeviceF-ospf-1] area 2
[*DeviceF-ospf-1-area-0.0.0.2] network 172.17.1.0 0.0.0.255
[*DeviceF-ospf-1-area-0.0.0.2] commit
[~DeviceF-ospf-1-area-0.0.0.2] quit
```

Step 3 Configure ciphertext authentication for the OSPF area.

Configure DeviceA.

```
[~DeviceA] ospf 1
[*DeviceA-ospf-1] area 0
[*DeviceA-ospf-1-area-0.0.0.0] authentication-mode hmac-sha256 1 cipher YsHsjx_202206
[*DeviceA-ospf-1-area-0.0.0.0] quit
[*DeviceA-ospf-1] commit
```

Configure DeviceB.

```
[~DeviceB] ospf 1
[*DeviceB-ospf-1] area 0
[*DeviceB-ospf-1-area-0.0.0.0] authentication-mode hmac-sha256 1 cipher YsHsjx_202206
[*DeviceB-ospf-1-area-0.0.0.0] quit
[*DeviceB-ospf-1] commit
```

Device B and Device A must be configured with the same password. Otherwise, the neighbor relationship cannot be established.

Step 4 Verify the configuration.

Display the OSPF neighbors of DeviceA.

```
[~DeviceA] display ospf peer

Example for Configuring OSPF Virtual Links

This section describes how to configure virtual links to connect a non-backbone area to the backbone area.

Networking Requirements

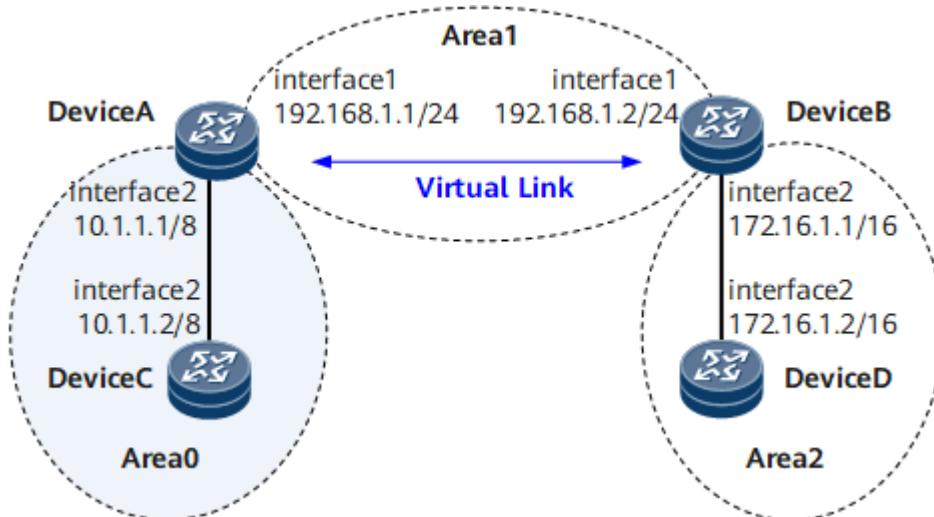

On the network shown in [Figure 1-127](#), Area 2 is not directly connected to the backbone area Area 0. Area 1 serves as a transit area to connect Area 2 and Area 0. A virtual link is configured between DeviceA and DeviceB.

Figure 1-127 Networking for configuring an OSPF virtual links

NOTE

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

Precautions

The default value is recommended when a virtual link is created. You can modify the value in actual scenarios.

Suggestions for configuring parameters are as follows:

- The smaller the **hello** parameter, the more rapidly a router detects network topology change, the more network resources are consumed.
- If the **retransmit** parameter is set too small, LSAs may be retransmitted. Setting the parameter to a large value is recommended in a low-speed network.
- The authentication modes of a virtual link and the backbone area must be the same.
- To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPF functions on each router.
2. Configure a virtual link between DeviceA and DeviceB to connect a non-backbone area to the backbone area.

Data Preparation

To complete the configuration, you need the following data:

Device Name	Router ID	Process ID	IP Address
-------------	-----------	------------	------------

DeviceA	1.1.1.1	1	Area 0: 10.0.0.0/8 Area 1: 192.168.1.0/24
DeviceB	2.2.2.2	1	Area 1: 192.168.1.0/24 Area 2: 172.16.0.0/16
DeviceC	3.3.3.3	1	Area 0: 10.0.0.0/8
DeviceD	4.4.4.4	1	Area 2: 172.16.0.0/16

Procedure

Step 1 Assign an IP address to each interface according to [Configuration Files](#). For configuration details, see Configuration Files in this section.

Step 2 Configure basic OSPF functions.

[Configuring Basic OSPF Functions](#) shows how to configure basic OSPF functions. For configuration details, see Configuration Files in this section.

Step 3 Check the OSPF routes on DeviceA

```
[~DeviceA] display ospf routing
      OSPF Process 1 with Router ID 1.1.1.1
      Routing Tables

      Routing for Network
      Destination    Cost     Type    NextHop      AdvRouter      Area
      10.0.0.0/8      1       Transit   10.1.1.1    3.3.3.3      0.0.0.0
      192.168.1.0/24  1       Transit   192.168.1.1  1.1.1.1      0.0.0.1

      Total Nets: 2
      Intra Area: 2 Inter Area: 0 ASE: 0 NSSA: 0
```

The routing table on Device A contains no route in Area 2 because Area 2 is not directly connected to Area 0.

Step 4 Configure an OSPF virtual link.

Configure DeviceA.

```
[~DeviceA] router id 1.1.1.1
[~DeviceA] ospf 1
[*DeviceA-ospf-1] area 1
[*DeviceA-ospf-1-area-0.0.0.1] vlink-peer 2.2.2.2
[*DeviceA-ospf-1-area-0.0.0.1] quit
[*DeviceA-ospf-1] quit
[*DeviceA] commit
```

Configure DeviceB.

```
[~DeviceB] router id 2.2.2.2
[~DeviceB] ospf 1
[*DeviceB-ospf-1] area 1
```

```
[*DeviceB-ospf-1-area-0.0.0.1] vlink-peer 1.1.1.1
[*DeviceB-ospf-1-area-0.0.0.1] quit
[*DeviceB-ospf-1] quit
[*DeviceB] commit
```

Step 5 Verify the configuration.

Display the OSPF vlink on DeviceA.

```
[~DeviceA] display ospf vlink
    OSPF Process 1 with Router ID 1.1.1.1
        Virtual Links
    Virtual-link Neighbor-id -> 2.2.2.2, Neighbor-State: Full
    Interface: 192.168.1.1 (GigabitEthernet1/0/0)
    Cost: 1 State: P-2-P Type: Virtual
    Transit Area: 0.0.0.1
    Timers: Hello 10 , Dead 40 , Retransmit 5 , Transmit Delay 1
    GR State: Normal
```

The preceding command output shows that the OSPF vlink neighbor status is "Full".

Display the OSPF routes on DeviceA.

```
[~DeviceA] display ospf routing
    OSPF Process 1 with Router ID 1.1.1.1
        Routing Tables

    Routing for Network
    Destination      Cost      Type      Nexthop      AdvRouter      Area
    172.16.0.0/16    2        Inter-area 192.168.1.2  2.2.2.2      0.0.0.2
    10.0.0.0/8       1        Transit    10.1.1.1    1.1.1.1      0.0.0.0
    192.168.1.0/24   1        Transit    192.168.1.1  1.1.1.1      0.0.0.1

    Total Nets: 3
    Intra Area: 2 Inter Area: 1 ASE: 0 NSSA: 0
```

After the virtual link is configured, the routing table on DeviceA contains routes in Area 2.

----End

Example for Configuring an OSPF Stub Area

This section describes how to configure a stub area that imports static routes. Such configuration can reduce the number of LSAs advertised to this area without affecting route reachability.

Networking Requirements

On the network shown in [Figure 1-128](#), all routers run OSPF, and the entire AS is divided into three areas. DeviceA and DeviceB function as ABRs to advertise inter-

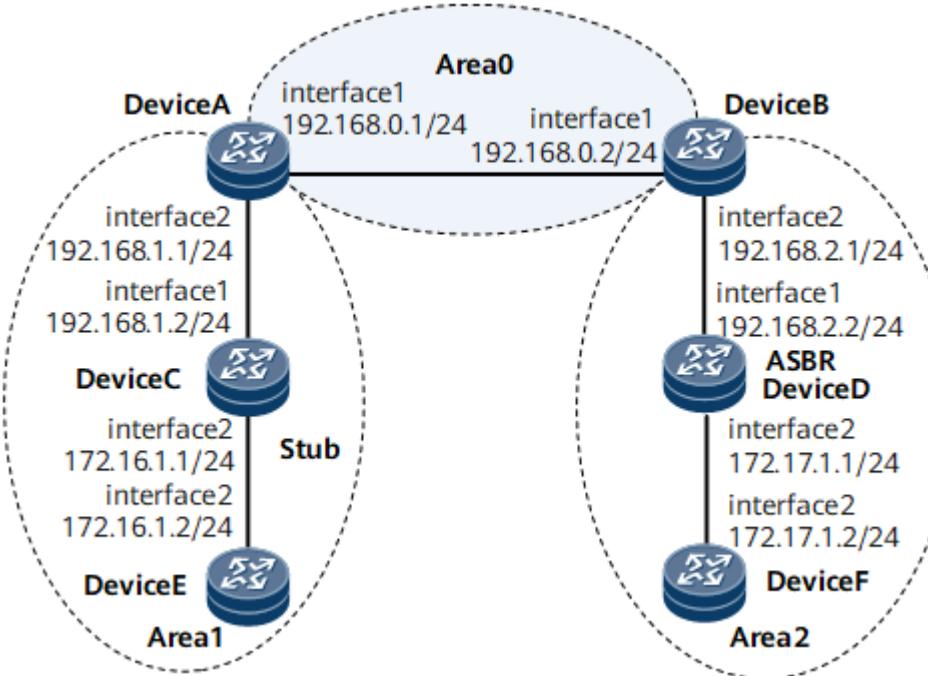

area routes; DeviceD functions as the ASBR and imports external routes (static routes).

Configure Area 1 as a stub area to reduce the LSAs advertised to this area without affecting route reachability.

Figure 1-128 Networking for configuring an OSPF stub area

 NOTE

Interfaces 1 and 2 in this example represent GE1/0/0 and GE2/0/0, respectively.

Precautions

When configuring an OSPF stub area, note the following rules:

- The backbone area cannot be configured as a stub area.
- An ASBR cannot exist in a stub area. That is, AS-external routes are not flooded in the stub area.
- A virtual link cannot pass through a stub area.
- To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPF functions on each router for interconnection.

2. Configure a static route on DeviceD and import it into OSPF.
3. Configure Area 1 as a stub area by running the **stub** command on all routers in Area 1 and check the OSPF routing information on DeviceC.
4. Prevent DeviceA from advertising Type 3 LSAs to the stub area, and check the OSPF routing information on DeviceC.

Data Preparation

To complete the configuration, you need the following data:

Device Name	Router ID	Process ID	IP Address
DeviceA	1.1.1.1	1	Area 0: 192.168.0.0/24 Area 1: 192.168.1.0/24
DeviceB	2.2.2.2	1	Area 0: 192.168.0.0/24 Area 2: 192.168.2.0/24
DeviceC	3.3.3.3	1	Area 1: 192.168.1.0/24 and 172.16.1.0/24
DeviceD	4.4.4.4	1	Area 2: 192.168.2.0/24 and 172.17.1.0/24
DeviceE	5.5.5.5	1	Area 1: 172.16.1.0/24
DeviceF	6.6.6.6	1	Area 2: 172.17.1.0/24

Procedure

- Step 1** Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure basic OSPF functions. For details, see [Example for Configuring Basic OSPF Functions](#).
- Step 3** Configure DeviceD to import static routes.

```
[*DeviceD] ip route-static 10.0.0.0 8 null 0
[*DeviceD] ospf 1
[*DeviceD-ospf-1] import-route static type 1
[*DeviceD-ospf-1] commit
```

```

192.168.0.0/24 2 Inter-area 192.168.1.1 1.1.1.1 0.0.0.1
192.168.2.0/24 3 Inter-area 192.168.1.1 1.1.1.1 0.0.0.1

Total Nets: 4
Intra Area: 0 Inter Area: 4 ASE: 0 NSSA: 0
```

Step 5 # Prevent DeviceA from advertising Type 3 LSAs to the stub area.

```
[~DeviceA] ospf
[*DeviceA-ospf-1] area 1
[*DeviceA-ospf-1-area-0.0.0.1] stub no-summary
[*DeviceA-ospf-1-area-0.0.0.1] commit
[~DeviceA-ospf-1-area-0.0.0.1] quit
```

Step 6 Verify the configuration.

Display the OSPF routing table on DeviceC.

```
[~DeviceC] display ospf routing
OSPF Process 1 with Router ID 3.3.3.3
    Routing Tables

Routing for Network
Destination Cost Type NextHop AdvRouter Area
0.0.0.0/0 2 Inter-area 192.168.1.1 1.1.1.1 0.0.0.1

Total Nets: 1
Intra Area: 0 Inter Area: 1 ASE: 0 NSSA: 0
```

 NOTE

After the advertisement of summary LSAs to the stub area is disabled, the number of routing entries on the routers in the stub area further decreases, and only the default route to a destination beyond the stub area is reserved.

----End

Example for Configuring an OSPF NSSA

This section describes how to configure an OSPF not-so-stubby area (NSSA).

Networking Requirements

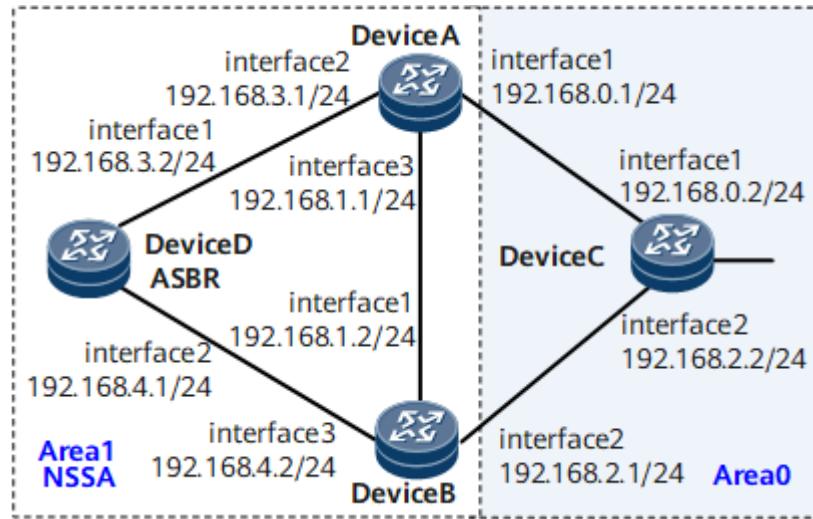

An excessive number of entries in a routing table wastes network resources and causes high CPU usage. To solve this problem, a non-backbone area on the border of an AS can be configured as an NSSA to reduce the amount of routing information to be transmitted. An NSSA in an AS does not transmit routes learned from other areas in the AS but imports AS external routes. This reduces bandwidth and storage resource consumption.

On the network shown in [Figure 1-129](#), all routers run OSPF and the entire AS is divided into two areas. DeviceA and DeviceB function as Area Border Routers (ABRs) to forward inter-area routes; DeviceD functions as an Autonomous System Boundary Router (ASBR) and imports the external static route 10.0.0.0/8. To import AS-external routes but reduce the number of Link State Advertisements (LSAs) advertised to area 1 without affecting route reachability, configure area 1 as an NSSA and configure DeviceA as an LSA translator in the NSSA.

Figure 1-129 Networking for configuring an OSPF NSSA

 NOTE

Interfaces 1 through 3 in this example represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

Configuration Roadmap

The configuration roadmap is as follows:

1. Enable OSPF on all routers and configure basic OSPF functions to ensure that routers communicate with each other using OSPF. For details, see [1.1.4.2.3 Configuring Basic OSPF Functions](#).
2. Configure area 1 as an NSSA.
3. Configure DeviceD to import the static route 10.0.0.0/8.
4. Configure DeviceA in the NSSA as an LSA translator.

Data Preparation

To complete the configuration, you need the following data:

- Router ID 1.1.1.1 of DeviceA; OSPF process ID 1; network segment 192.168.0.0/24 of area 0; network segments 192.168.1.0/24 and 192.168.3.0/24 of area 1
- Router ID 2.2.2.2 of DeviceB; OSPF process ID 1; network segment 192.168.2.0/24 of area 0; network segments 192.168.1.0/24 and 192.168.4.0/24 of area 1

- Router ID 3.3.3.3 of DeviceC; OSPF process ID 1; network segments 192.168.0.0/24 and 192.168.2.0/24 of area 0
- Router ID 4.4.4.4 of DeviceD; OSPF process ID 1; network segments 192.168.3.0/24 and 192.168.4.0/24 of area 1

Procedure

Step 1 Assign an IP address to each interface.

Configure an IP address for each interface as shown in [Figure 1-129](#). For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure basic OSPF functions.

[1.1.4.2.3 Configuring Basic OSPF Functions](#) shows how to configure basic OSPF functions. For details about the configuration, see [Configuration Files](#) in this section.

Step 3 Configure area 1 as an NSSA.

Configure DeviceA.

```
[~DeviceA] ospf  
[*DeviceA-ospf-1] area 1  
[*DeviceA-ospf-1-area-0.0.0.1] nssa  
[*DeviceA-ospf-1-area-0.0.0.1] commit  
[~DeviceA-ospf-1-area-0.0.0.1] quit
```

Configure DeviceB.

```
[~DeviceB] ospf  
[*DeviceB-ospf-1] area 1  
[*DeviceB-ospf-1-area-0.0.0.1] nssa  
[*DeviceB-ospf-1-area-0.0.0.1] commit  
[~DeviceB-ospf-1-area-0.0.0.1] quit
```

Configure DeviceD.

```
[~DeviceD] ospf  
[*DeviceD-ospf-1] area 1  
[*DeviceD-ospf-1-area-0.0.0.1] nssa  
[*DeviceD-ospf-1-area-0.0.0.1] commit  
[~DeviceD-ospf-1-area-0.0.0.1] quit
```

NSSA attributes must be configured on all routers in the NSSA using the **nssa** command.

Step 4 Configure DeviceD to import the static route 10.0.0.0/8.

```
[~DeviceD] ip route-static 10.0.0.0 8 null 0  
[~DeviceD] ospf  
[*DeviceD-ospf-1] import-route static  
[*DeviceD-ospf-1] commit  
[~DeviceD-ospf-1] quit
```

Display the OSPF routing table on DeviceC.

```
[~DeviceC] display ospf routing  
OSPF Process 1 with Router ID 3.3.3.3  
      Routing Tables  
  
      Routing for Network  
      Destination   Cost  Type    NextHop      AdvRouter   Area  
      192.168.3.0/24  2     Inter-area 192.168.0.1  1.1.1.1    0.0.0.0  
      192.168.4.0/24  2     Inter-area 192.168.2.1  2.2.2.2    0.0.0.0
```

```
192.168.0.0/24 1 Stub 192.168.0.2 3.3.3.3 0.0.0.0
192.168.1.0/24 2 Inter-area 192.168.0.1 1.1.1.1 0.0.0.0
192.168.1.0/24 2 Inter-area 192.168.2.1 2.2.2.2 0.0.0.0
192.168.2.0/24 1 Stub 192.168.2.2 3.3.3.3 0.0.0.0

Routing for ASEs
Destination Cost Type Tag NextHop AdvRouter
10.0.0/8 1 Type2 1 192.168.2.1 2.2.2.2

Total Nets: 7
Intra Area: 2 Inter Area: 4 ASE: 1 NSSA: 0
```

The command output shows that the router ID of the router that advertised the AS external route imported to the NSSA is 2.2.2.2. That is, DeviceB functions as a translator router because OSPF selects the ABR with the largest router ID as a translator router.

Step 5 # Configure DeviceA as an LSA translator.

```
[~DeviceA] ospf
[*DeviceA-ospf-1] area 1
[*DeviceA-ospf-1-area-0.0.0.1] nssa default-route-advertise no-summary translator-always
[*DeviceA-ospf-1-area-0.0.0.1] commit
[~DeviceA-ospf-1-area-0.0.0.1] quit
```

Step 6 Verify the configuration.

View the OSPF routing table on DeviceC.

```
[~DeviceC] display ospf routing
OSPF Process 1 with Router ID 3.3.3.3
      Routing Tables

      Routing for Network
      Destination Cost Type NextHop AdvRouter Area
      192.168.3.0/24 2 Inter-area 192.168.0.1 1.1.1.1 0.0.0.0
      192.168.4.0/24 2 Inter-area 192.168.2.1 2.2.2.2 0.0.0.0
      192.168.0.0/24 1 Stub 192.168.0.2 3.3.3.3 0.0.0.0
      192.168.1.0/24 2 Inter-area 192.168.2.1 2.2.2.2 0.0.0.0
      192.168.1.0/24 2 Inter-area 192.168.0.1 1.1.1.1 0.0.0.0
      192.168.2.0/24 1 Stub 192.168.2.2 3.3.3.3 0.0.0.0

      Routing for ASEs
      Destination Cost Type Tag NextHop AdvRouter
      10.0.0/8 1 Type2 1 192.168.0.1 1.1.1.1

Total Nets: 7
Intra Area: 2 Inter Area: 4 ASE: 1 NSSA: 0
```

The command output shows that DeviceC has imported an AS external route and that the router ID of the router that advertised the imported AS external route is 1.1.1.1. DeviceA functions as the translator router.

----End

Example for Configuring OSPF DR Election

This section describes how to set the DR priority on an interface for DR election on a broadcast network.

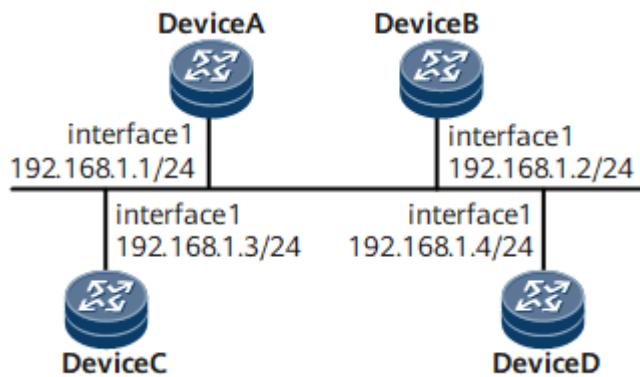

Networking Requirements

On the network shown in [Figure 1-130](#), the interface of DeviceA has the highest priority of 100 on the network and is elected as the DR; DeviceC has the second highest priority and is elected as the BDR. DeviceB has the priority of 0 and cannot be elected as a DR or a BDR; no priority is configured for DeviceD and therefore, DeviceD uses the default value (1).

Figure 1-130 Networking for configuring OSPF DR election

Interface 1 in this example represents GE 1/0/0.

Precautions

Reconfiguring the DR priority for a router does not change the DR or BDR on a network. You can use either of the following methods to re-elect a DR or BDR.

However, the following methods will disconnect OSPF neighbors. Therefore, use the following methods only when necessary.

- Restart the OSPF processes on all routers.
- Configure the **shutdown** and **undo shutdown** commands on the interfaces where the OSPF neighboring relationships are established.
- To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPF functions on each router for interconnection.
2. Configure a router ID for each router.
3. Check the DR or BDR status on each router when the default priority is used.
4. Configure the DR priority on an interface and check whether the device is the DR or BDR.

Data Preparation

To complete the configuration, you need the following data:

- Router ID (1.1.1.1) and priority (100) of DeviceA
- Router ID (2.2.2.2) and priority (0) of DeviceB
- Router ID (3.3.3.3) and priority (2) of DeviceC
- Router ID (4.4.4.4) and priority (1) of DeviceD

Procedure

Step 1 Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure basic OSPF functions.

Configure DeviceA.

```
[~DeviceA] router id 1.1.1.1
[*DeviceA] ospf 1
[*DeviceA-ospf-1] area 0
[*DeviceA-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[*DeviceA-ospf-1-area-0.0.0.0] commit
[~DeviceA-ospf-1-area-0.0.0.0] quit
```

Configure DeviceB.

```
[~DeviceB] router id 2.2.2.2
[*DeviceB] ospf 1
[*DeviceB-ospf-1] area 0
[*DeviceB-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[*DeviceB-ospf-1-area-0.0.0.0] commit
[~DeviceB-ospf-1-area-0.0.0.0] quit
```

Configure DeviceC.

```
[~DeviceC] router id 3.3.3.3
[*DeviceC] ospf 1
[*DeviceC-ospf-1] area 0
[*DeviceC-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[*DeviceC-ospf-1-area-0.0.0.0] commit
[~DeviceC-ospf-1-area-0.0.0.0] quit
```

Configure DeviceD.

```
[~DeviceD] router id 4.4.4.4
[*DeviceD] ospf 1
[*DeviceD-ospf-1] area 0
[*DeviceD-ospf-1-area-0.0.0.0] network 192.168.1.0 0.0.0.255
[*DeviceD-ospf-1-area-0.0.0.0] commit
[~DeviceD-ospf-1-area-0.0.0.0] quit
```

Display the status of the DR or BDR.

```
[~DeviceA] display ospf peer
OSPF Process 1 with Router ID 1.1.1.1
Neighbors

Area 0.0.0.0 interface 192.168.1.1 ( GE1/0/0 )'s neighbors
Router ID: 2.2.2.2      Address: 192.168.1.2
  State: 2-Way Mode:Nbr is Slave Priority: 1
  DR: 192.168.1.4  BDR: 192.168.1.3  MTU: 0
  Dead timer due in 32 sec
  Retrans timer interval: 0
  Neighbor is up for 1h15m4s
  Neighbor up time : 2020-06-08 01:41:57
  Authentication Sequence: [ 0 ]

Area 0.0.0.0 interface 192.168.1.1 ( GE1/0/0 )'s neighbors
Router ID: 3.3.3.3      Address: 192.168.1.3
  State: Full Mode:Nbr is Master Priority: 1
  DR: 192.168.1.4  BDR: 192.168.1.3  MTU: 0
  Dead timer due in 34 sec
  Retrans timer interval: 5
  Neighbor is up for 1h15m4s
  Neighbor up time : 2020-06-08 01:41:57
  Authentication Sequence: [ 0 ]

Area 0.0.0.0 interface 192.168.1.1 ( GE1/0/0 )'s neighbors
Router ID: 4.4.4.4      Address: 192.168.1.4
  State: Full Mode:Nbr is Master Priority: 1
  DR: 192.168.1.4  BDR: 192.168.1.3  MTU: 0

```

Display the status of OSPF interfaces.

```
[~DeviceA] display ospf interface
2020-11-21 15:55:20.606

(M) Indicates MADJ interface
      OSPF Process 1 with Router ID 1.1.1.1
      Interfaces

Area: 0.0.0.0 (MPLS TE not enabled)
Interface      IP Address      Type      State  Cost  Pri
GigabitEthernet1/0/0  192.168.1.1  Broadcast  DR    1    100

[~DeviceB] display ospf interface
2020-11-21 15:55:20.606

(M) Indicates MADJ interface

      OSPF Process 1 with Router ID 2.2.2.2
      Interfaces

Area: 0.0.0.0 (MPLS TE not enabled)
Interface      IP Address      Type      State  Cost  Pri
GigabitEthernet1/0/0  192.168.1.2  Broadcast  DROther  1    100
```

If the neighbor is in the Full state, the device has established a neighbor relationship with its neighbor. If the neighbor remains in the 2-Way state, neither of them is the DR or BDR. In this case, they do not need to exchange LSAs.

If the status of the OSPF interface is DROther, the interface is neither DR nor BDR.

## Example for Configuring OSPF Load Balancing

This section describes how to configure OSPF load balancing, including enabling load balancing and setting priorities for equal-cost routes.

## Networking Requirements

On the network shown in [Figure 1-131](#):

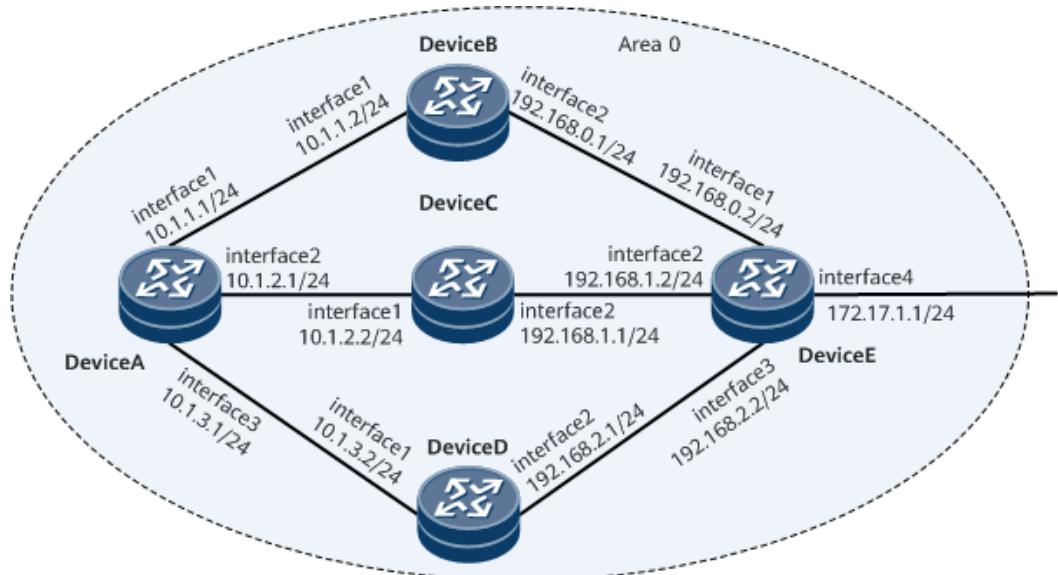

- DeviceA, DeviceB, DeviceC, DeviceD, and DeviceE are connected to each other through OSPF.
- DeviceA, DeviceB, DeviceC, DeviceD, and DeviceE belong to Area 0.

- Load balancing is configured so that the traffic from DeviceA to DeviceE is load-balanced by DeviceC and DeviceD.

**Figure 1-131** Networking for configuring OSPF load balancing

 **NOTE**

In this example, interface1, interface2, interface3, and interface4 represent GE1/0/0, GE2/0/0, GE3/0/0, and GE1/0/1, respectively.

## Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

- Configure basic OSPF functions on each router for interconnection.
- Configure load balancing on DeviceA.
- Set the priority for equal-cost routes on DeviceA.
- Configure per-packet load balancing on DeviceA.

## Data Preparation

To complete the configuration, you need the following data.

- Data of DeviceA, including router ID (1.1.1.1), OSPF process ID (1), and network segment addresses of Area 0 (10.1.1.0/24, 10.1.2.0/24 and 10.1.3.0/24)
- Data of DeviceB, including router ID (2.2.2.2), OSPF process ID (1), and network segment addresses of area 0 (10.1.1.0/24 and 192.168.0.0/24)

- Data of DeviceC, including router ID (3.3.3.3), OSPF process ID (1), and network segment addresses of area 0 (10.1.2.0/24 and 192.168.1.0/24)
- Data of DeviceD, including router ID (4.4.4.4), OSPF process ID (1), and network segment addresses of area 0 (10.1.3.0/24 and 192.168.2.0/24)
- Data of DeviceE, including router ID (5.5.5.5), OSPF process ID (1), and network segment addresses of area 0 (192.168.0.0/24, 192.168.1.0/24, 192.168.2.0/24, and 172.17.1.0/24)
- Number of equal-cost routes for load balancing on DeviceA (2)
- Next hop weights of the routes from DeviceA to DeviceB, DeviceC, and DeviceD (2, 1, and 1, respectively)

## Procedure

- Step 1** Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure basic OSPF functions. For details, see [Example for Configuring Basic OSPF Functions](#).
- Step 3** Display the routing table of DeviceA.

DeviceA has three valid next hops: DeviceB (10.1.1.2), DeviceC (10.1.2.2), and DeviceD (10.1.3.2) because the default maximum number of equal-cost routes is 64.

```
<DeviceA> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: _public_
Destinations : 15 Routes : 15
Destination/Mask Proto Pre Cost Flags NextHop Interface
10.1.1.0/24 Direct 0 0 D 10.1.1.1 GigabitEthernet1/0/0

192.168.0.0/24 OSPF 10 2 D 10.1.1.2 GigabitEthernet1/0/0
192.168.1.0/24 OSPF 10 2 D 10.1.2.2 GigabitEthernet2/0/0
192.168.2.0/24 OSPF 10 2 D 10.1.2.2 GigabitEthernet3/0/0
172.17.1.0/24 OSPF 10 3 D 10.1.1.2 GigabitEthernet1/0/0
 OSPF 10 3 D 10.1.2.2 GigabitEthernet2/0/0
 OSPF 10 3 D 10.1.3.2 GigabitEthernet3/0/0
```

- Step 4** Set the maximum number of routes for load balancing to 2 on DeviceA.

```
[~DeviceA] ospf 1
[*DeviceA-ospf-1] maximum load-balancing 2
[*DeviceA-ospf-1] commit
[~DeviceA-ospf-1] quit
```

# Check the routing table of DeviceA. The command output shows that DeviceA has two routes for load balancing. The maximum number of equal-cost routes is 2. Therefore, the next hops 10.1.1.2 (DeviceB) and 10.1.2.2 (DeviceC) are valid routes.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: _public_
Destinations : 15 Routes : 15

Destination/Mask Proto Pre Cost Flags NextHop Interface
10.1.1.0/24 Direct 0 0 D 10.1.1.1 GigabitEthernet1/0/0
10.1.1.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
10.1.1.2/32 Direct 0 0 D 10.1.1.2 GigabitEthernet1/0/0
10.1.2.0/24 Direct 0 0 D 10.1.2.1 GigabitEthernet2/0/0
10.1.2.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet2/0/0
10.1.2.2/32 Direct 0 0 D 10.1.2.2 GigabitEthernet2/0/0
10.1.3.0/24 Direct 0 0 D 10.1.2.1 GigabitEthernet3/0/0
10.1.3.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet3/0/0
10.1.3.2/32 Direct 0 0 D 10.1.2.2 GigabitEthernet3/0/0
127.0.0.0/8 Direct 0 0 D 127.0.0.1 InLoopBack0
127.0.0.1/32 Direct 0 0 D 127.0.0.1 InLoopBack0
192.168.0.0/24 OSPF 10 2 D 10.1.1.2 GigabitEthernet1/0/0
192.168.1.0/24 OSPF 10 2 D 10.1.2.2 GigabitEthernet2/0/0
192.168.2.0/24 OSPF 10 2 D 10.1.2.2 GigabitEthernet3/0/0
172.17.1.0/24 OSPF 10 3 D 10.1.1.2 GigabitEthernet1/0/0
OSPF 10 3 D 10.1.2.2 GigabitEthernet2/0/0
```

### Step 5 Set the priority for equal-cost routes on DeviceA.

```
[~DeviceA] ospf 1
[*DeviceA-ospf-1] nexthop 10.1.1.2 weight 2
[*DeviceA-ospf-1] nexthop 10.1.2.2 weight 1
[*DeviceA-ospf-1] nexthop 10.1.3.2 weight 1
[*DeviceA-ospf-1] commit
[*DeviceA-ospf-1] quit
```

### Step 6 Verify the configuration.

# Check the routing table of DeviceA.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: _public_
Destinations : 15 Routes : 15

Destination/Mask Proto Pre Cost Flags NextHop Interface
10.1.1.0/24 Direct 0 0 D 10.1.1.1 GigabitEthernet1/0/0
10.1.1.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
10.1.1.2/32 Direct 0 0 D 10.1.1.2 GigabitEthernet1/0/0
10.1.2.0/24 Direct 0 0 D 10.1.2.1 GigabitEthernet2/0/0
10.1.2.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet2/0/0
10.1.2.2/32 Direct 0 0 D 10.1.2.2 GigabitEthernet2/0/0
10.1.3.0/24 Direct 0 0 D 10.1.2.1 GigabitEthernet3/0/0
10.1.3.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet3/0/0
10.1.3.2/32 Direct 0 0 D 10.1.2.2 GigabitEthernet3/0/0
127.0.0.0/8 Direct 0 0 D 127.0.0.1 InLoopBack0
127.0.0.1/32 Direct 0 0 D 127.0.0.1 InLoopBack0
192.168.0.0/24 OSPF 10 2 D 10.1.1.2 GigabitEthernet1/0/0
192.168.1.0/24 OSPF 10 2 D 10.1.2.2 GigabitEthernet2/0/0
192.168.2.0/24 OSPF 10 2 D 10.1.2.2 GigabitEthernet3/0/0
172.17.1.0/24 OSPF 10 3 D 10.1.2.2 GigabitEthernet2/0/0
OSPF 10 3 D 10.1.3.2 GigabitEthernet3/0/0
```

As shown in the routing table, the priority of the route with 10.1.2.2 and 10.1.3.2 as the next hop addresses is higher than that of the route with 10.1.1.2 as the next hop address. Therefore, DeviceA has only two valid next hops, DeviceC (10.1.2.2) and DeviceD (10.1.3.2).

----End

## Example for Configuring OSPF Fast Convergence

This section describes how to configure OSPF fast convergence by adjusting the timer parameter and configuring BFD.

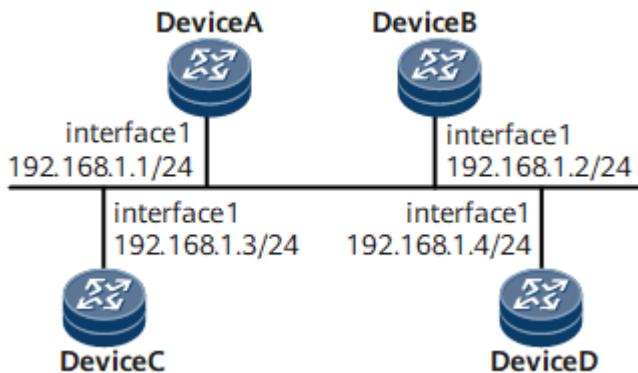

## Networking Requirements

On the broadcast network shown in [Figure 1-132](#), OSPF runs on the four devices, which belong to the same OSPF area.

**Figure 1-132** Networking for configuring OSPF fast convergence

Interface 1 in this example represents GE1/0/0.

## Precautions

When configuring OSPF fast convergence, note the following rules:

- You can decrease the interval at which Hello packets are sent and values of the Dead, Poll, and Wait timers for fast OSPF network convergence. Frequent packet transmission, however, may overload the device. In addition, the OSPF network convergence slows down if the values of these timers are too large. Therefore, set values based on the network stability.
- The intervals at which Hello packets are sent and values of the Dead, Poll, and Wait timers at both ends must be the same. Otherwise, the OSPF neighbor relationship cannot be established.
- To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPF functions on each router for interconnection.
2. Configure the BFD function on each router.
3. Adjust the holddown time of the OSPF neighbors on each router.
4. Configure the Smart-discover function on each router.
5. Adjust the intervals for configuration update, LSA reception, and SPF calculation through an intelligent timer on each router.

## Data Preparation

To complete the configuration, you need the following data:

- Holddown time of the OSPF neighbors
- Intervals for LSA update, LSA reception, and SPF calculation

## Procedure

- Step 1** Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure basic OSPF functions. For details, see [Example for Configuring Basic OSPF Functions](#).
- Step 3** Adjust the holddown time of the OSPF neighbors on each router.

# Configure Device A.

```
[~DeviceA] interface gigabitethernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] ospf timer dead 30
[*DeviceA-GigabitEthernet1/0/0] commit
```

### NOTE

- The holddown time of neighbors of the OSPF-capable interfaces must be longer than the interval at which Hello packets are sent, and the values of **dead interval** on the routers in the same network segment must be the same.
- In this configuration example, the following configurations on each router are the same as that on DeviceA. For configuration details, see Configuration Files in this section.
  - Adjust the holddown time of the OSPF neighbors on each router.
  - Configure the Smart-discover function on each router.
  - Adjust the intervals for configuration update, LSA reception, and SPF calculation through an intelligent timer on the router.

- Step 4** Configure the Smart-discover function on each router.

# Configure DeviceA.

```
[*DeviceA-GigabitEthernet1/0/0] ospf smart-discover
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
```

- Step 5** Configure the BFD function on each router.

# Configure DeviceA.

```
[~DeviceA] bfd
[*DeviceA-bfd] quit
[~DeviceA] ospf
[*DeviceA-ospf-1] bfd all-interfaces enable
[*DeviceA-ospf-1] commit
[~DeviceA-ospf-1] quit
```

- Step 6** Adjust the intervals for configuration update, LSA reception, and SPF calculation through an intelligent timer on each router.

# Configure DeviceA.

```
[~DeviceA] ospf 1
[~DeviceA-ospf-1] lsa-arrival-interval intelligent-timer 3000 200 500
[*DeviceA-ospf-1] lsa-originate-interval intelligent-timer 3000 200 500
[*DeviceA-ospf-1] spf-schedule-interval intelligent-timer 3000 200 500
[*DeviceA-ospf-1] commit
```

- Step 7** Verify the configuration.

```
Run the display ospf brief command on each router to view the brief information about OSPF. Use Router A as an example. You can view the values of timers.
```

```
[~DeviceA] display ospf brief

## Example for Configuring OSPF Local MT

This section provides an example for configuring OSPF local multicast topology (MT).

### Networking Requirements

When both multicast and MPLS TE tunnels are configured on a network and the TE tunnels are configured with IGP Shortcut, the outbound interface that an IGP calculates for a route may be not a physical interface but a TE tunnel interface. The TE tunnel interface on the Device sends multicast Join packets over a unicast route to the multicast source address. The multicast Join packets are transparent to the Device through which the TE tunnel passes. As a result, the Device through which the TE tunnel passes cannot generate multicast forwarding entries.

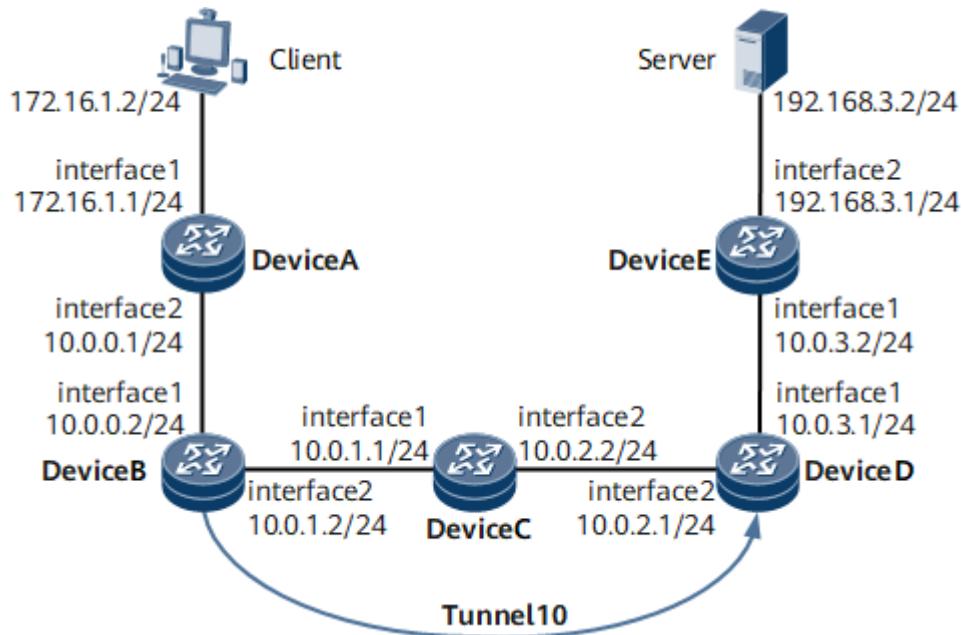

On the network shown in [Figure 1-133](#), DeviceA, DeviceB, DeviceC, DeviceD, and DeviceE are running OSPF. DeviceB and DeviceD set up an MPLS TE tunnel with the tunnel interface Tunnel 10, and IGP Shortcut is enabled on Tunnel 10 of DeviceB. The outbound interface calculated by DeviceB may be the TE tunnel interface, not the physical interface GE 2/0/0. Interface TE tunnel 10 on DeviceB sends multicast Join messages over a unicast route to the multicast source address. The multicast Join messages are transparent to DeviceC spanned by TE tunnel 10. As a result, DeviceC cannot generate multicast forwarding entries.

To resolve the problem, enable OSPF local MT on DeviceB. After local MT is enabled, if the outbound interface of a calculated route is an IGP Shortcut-enabled TE tunnel interface, the route management (RM) module creates an independent Multicast IGP (MIGP) routing table for the multicast protocol, calculates a physical outbound interface for the route, and adds the route to the MIGP routing table. Multicast packets are then forwarded along this route.

**Figure 1-133** Configuring local OSPF MT

 NOTE

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

## Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Enable OSPF and configure basic OSPF functions on each Device.
2. Enable PIM-SM on each Device.
3. Configure an MPLS Resource Reservation Protocol (RSVP)-TE tunnel.
4. Configure an MPLS TE tunnel and enable IGP Shortcut for it on DeviceB.
5. Enable OSPF local MT on DeviceB.

## Data Preparation

To complete the configuration, you need the following data:

- **Table 1-51** lists the IP addresses of interfaces on the router.

**Table 1-51** IP address of each interface

| Device  | IP Address of Loopback 0 |
|---------|--------------------------|
| DeviceA | 1.1.1.1/32               |
| DeviceB | 2.2.2.2/32               |

| Device  | IP Address of Loopback 0 |
|---------|--------------------------|
| DeviceC | 3.3.3.3/32               |
| DeviceD | 4.4.4.4/32               |
| DeviceE | 5.5.5.5/32               |

- The TE tunnel interface Tunnel 10 uses the IP address of Loopback 0 and runs the MPLS TE protocol. The destination address of the TE tunnel is 4.4.4.4, and the tunnel ID is 100. The TE tunnel uses RSVP-TE as a signaling protocol.

## Procedure

**Step 1** Assign an IP address to each interface.

[Figure 1-133](#) shows how to assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.

**Step 2** Configure basic OSPF functions.

[Configuring Basic OSPF Functions](#) shows how to configure basic OSPF functions. For configuration details, see [Configuration Files](#) in this section.

**Step 3** Configure Protocol Independent Multicast-Sparse Mode (PIM-SM).

# Enable PIM-SM on DeviceA.

```
[~DeviceA] multicast routing-enable
[*DeviceA] interface Gigabitethernet 2/0/0
[~DeviceA-GigabitEthernet2/0/0] pim sm
[*DeviceA-GigabitEthernet2/0/0] quit
[*DeviceA] interface Gigabitethernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] pim sm
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
```

Enable PIM-SM on each Device. The configurations for DeviceB, DeviceC, DeviceD, and DeviceE are similar to those on DeviceA. For configuration details, see [Configuration Files](#) in this section.

# Enable Internet Group Management Protocol (IGMP) on GE 1/0/0 of DeviceA.

```
[~DeviceA] interface Gigabitethernet 1/0/0
[~DeviceA-GigabitEthernet1/0/0] igmp enable
[*DeviceA-GigabitEthernet1/0/0] igmp version 3
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA-GigabitEthernet1/0/0] quit
```

# Configure a C-BSR and a C-RP. Set the service range of the RP on DeviceD and specify the locations of the C-BSR and the C-RP.

```
[~DeviceD] pim
[*DeviceD-pim] c-bsr LoopBack0
[*DeviceD-pim] c-rp LoopBack0
[*DeviceD-pim] commit
[~DeviceD-pim] quit
```

# Check the multicast routing table on DeviceC.

```
[~DeviceC] display multicast routing-table
```

```
Multicast routing table of VPN-Instance: public net
Total 3 entries

## Example for Configuring OSPF IP FRR

This section describes how to configure OSPF IP FRR with an example, including how to block FRR on certain interfaces to prevent the links connected to these interfaces from functioning as backup links and how to bind OSPF IP FRR to a BFD session.

## Networking Requirements

When a fault occurs on the primary link T, traffic is switched to a backup link. In such a scenario, two problems arise:

- It takes hundreds of milliseconds for the traffic to be switched to a backup link. During this period, services are interrupted.
- Traffic may be switched to the link that passes through DeviceA. DeviceA is an ASBR and is not expected to function as a backup device.

If a fault occurs on the network, OSPF IP FRR can fast switch traffic to the backup link without waiting for route convergence. This ensures uninterrupted traffic transmission. In addition, you can also prevent the link which passes through DeviceA from functioning as the FRR backup link.

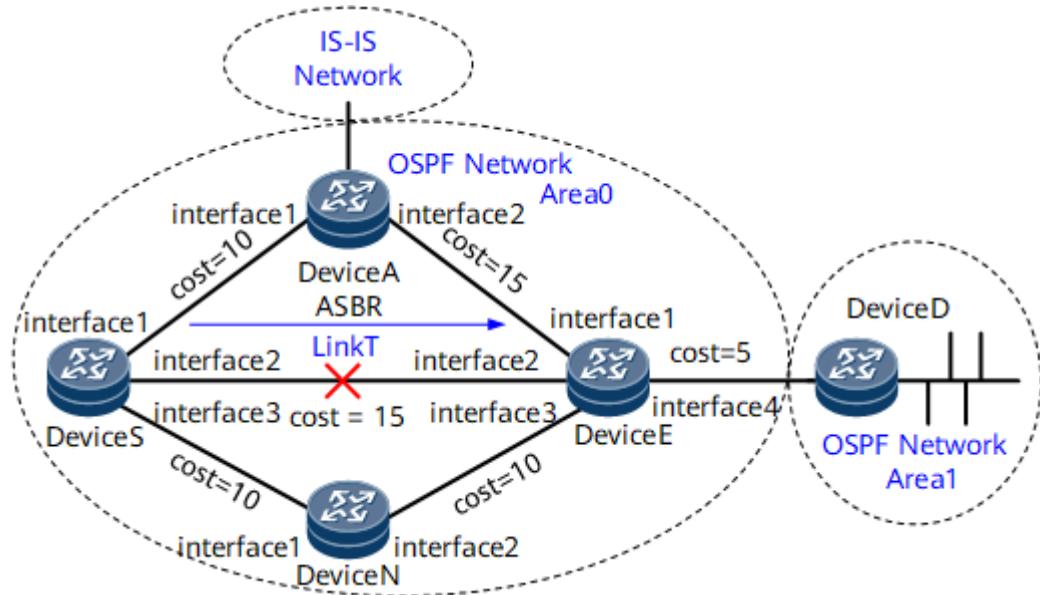

On the network shown in [Figure 1-134](#):

- All routers run OSPF.
- The link cost meets the OSPF IP FRR traffic protection inequality.
- If the primary link T fails, Device S immediately switches traffic to the backup link which passes through DeviceN.
- Based on the network planning, the link which passes through DeviceA does not function as an FRR backup link.

[Figure 1-134](#) Networking for configuring OSPF IP FRR

NOTE

Interfaces 1 through 4 in this example represent GE 1/0/0, GE 2/0/0, GE 3/0/0, and GE 1/0/1, respectively.

## Precautions

During the configuration, pay attention to the following points:

- Before configuring OSPF IP FRR, block FRR on certain interfaces to prevent the links connected to these interfaces from functioning as backup links. After that, the link where the interface resides is not calculated as a backup link during FRR calculation.
- During the configuration of OSPF IP FRR, the lower layer needs to fast respond to a link change so that traffic can be rapidly switched to the backup link. After the **bfd all-interfaces frr-binding** command is run, the BFD session status is bound to the link status of the interface (when the BFD session goes down, the link status of the interface also goes down). In this manner, faults can be rapidly detected.
- To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPF functions on each router.
2. Configure BFD for OSPF on all the devices in Area 0.
3. Set the costs of links to ensure that link T is selected to transmit traffic.
4. Block FRR on a specified interface of DeviceS.
5. Enable OSPF IP FRR on DeviceS to protect the traffic forwarded by DeviceS.

## Data Preparation

To complete the configuration, you need the following data:

| Device  | Router ID | Interface | IP Address    |
|---------|-----------|-----------|---------------|
| DeviceS | 1.1.1.1   | GE1/0/0   | 10.1.1.1/24   |
|         |           | GE2/0/0   | 10.1.2.1/24   |
|         |           | GE3/0/0   | 10.1.3.1/24   |
| DeviceA | 2.2.2.2   | GE1/0/0   | 10.1.1.2/24   |
|         |           | GE2/0/0   | 10.2.1.2/24   |
| DeviceN | 3.3.3.3   | GE1/0/0   | 10.1.3.2/24   |
|         |           | GE2/0/0   | 10.2.3.2/24   |
| DeviceE | 4.4.4.4   | GE1/0/0   | 10.2.1.1/24   |
|         |           | GE2/0/0   | 10.1.2.2/24   |
|         |           | GE3/0/0   | 10.2.3.1/24   |
|         |           | GE1/0/1   | 172.17.1.1/24 |

## Procedure

- Step 1** Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure basic OSPF functions. For details, see [Example for Configuring Basic OSPF Functions](#).
- Step 3** Configure BFD for OSPF on all the devices in Area 0. For details, see [Example for Configuring BFD for OSPF](#).
- Step 4** Set the costs of links to ensure that link T is selected to transmit traffic.

# Configure DeviceS.

```
[~DeviceS] interface gigabitethernet1/0/0
[*DeviceS-GigabitEthernet1/0/0] ospf cost 10

## Example for Configuring BFD for OSPF

This section describes how to configure BFD for OSPF. After BFD for OSPF is configured, BFD can fast detect link faults and report them to OSPF so that service traffic can be transmitted through the backup link.

## Networking Requirements

OSPF enables the device to periodically send Hello packets to a neighboring device for fault detection. Detecting a fault takes more than 1s. With the development of technologies, voice, video, and other VOD services are widely used. These services are quite sensitive to packet loss and delays. When traffic is transmitted at gigabit rates, long-time fault detection will cause packet loss. This cannot meet high reliability requirements of the carrier-class network. BFD for OSPF is used to resolve the problem. After BFD for OSPF is configured, the link status can be rapidly detected and fault detection can be completed in milliseconds. This speeds up OSPF convergence when the link status changes.

For example, as shown in [Figure 1-135](#), the primary link DeviceA -> DeviceB and the secondary link DeviceA -> DeviceC -> DeviceB are deployed on the network.

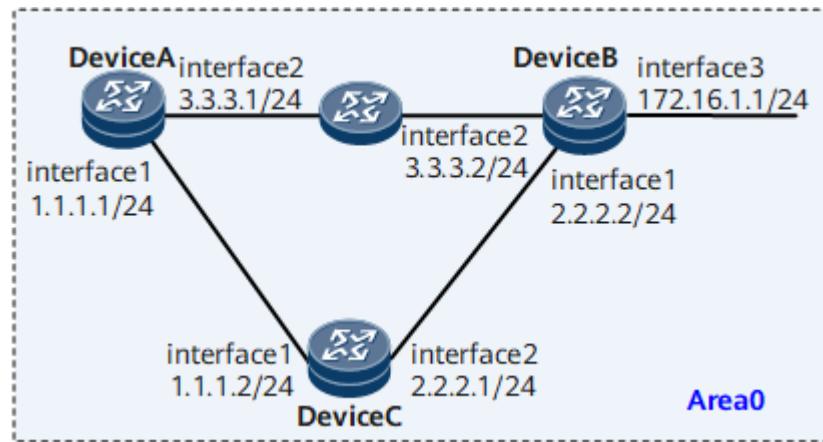

Traffic is transmitted on the primary link normally. When the primary link becomes faulty, the Device is expected to rapidly detect the fault and switch traffic to the secondary link.

You can configure BFD for OSPF to detect the OSPF neighbor relationship between DeviceA and DeviceB. When the link between DeviceA and DeviceB fails, BFD can rapidly detect the failure and report it to OSPF. Traffic is then switched to the secondary link.

**Figure 1-135 Networking for configuring BFD for OSPF**

 **NOTE**

Interfaces 1 through 3 in this example represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

## Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPF functions on each router for interconnection.
2. Enable global BFD.
3. Enable OSPF BFD on DeviceA and DeviceB.

## Data Preparation

To complete the configuration, you need the following data:

- Data of DeviceA, including the router ID (1.1.1.1), OSPF process number (1), and network segment addresses of Area 0 (3.3.3.0/24 and 1.1.1.0/24)

- Data of DeviceB, including the router ID (2.2.2.2), OSPF process number (1), and network segment addresses of Area 0 (3.3.3.0/24, 2.2.2.0/24, and 172.16.1.0/24)
- Data of DeviceC, including the router ID (3.3.3.3), OSPF process number (1), and network segment addresses of Area 0 (1.1.1.0/24 and 2.2.2.0/24)
- Minimum interval at which BFD packets are received and sent and local detection multiplier on DeviceA and DeviceB

## Procedure

**Step 1** Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.

**Step 2** Configure basic OSPF functions.

# Configure DeviceA.

```
[~DeviceA] router id 1.1.1.1
[*DeviceA] ospf 1

## Example for Configuring OSPF-BGP Synchronization

This section describes how to configure OSPF-BGP synchronization to minimize the impact of router restart on BGP services on the network.

### Networking Requirements

On the network shown in [Figure 1-136](#), all routers run BGP. An EBGP connection is set up between DeviceD and DeviceE. IBGP connections are set up between devices in AS 10, and OSPF is used as an IGP protocol.

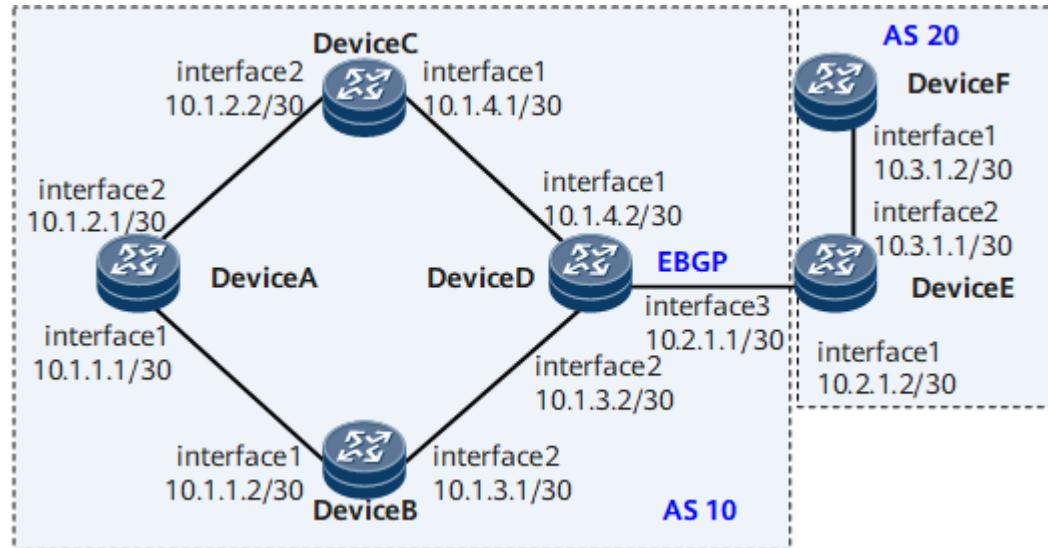

OSPF-BGP synchronization is required on DeviceB so that the restart of DeviceB does not interrupt the traffic from DeviceA to AS 20.

**Figure 1-136** Networking for configuring OSPF-BGP synchronization

#### NOTE

Interfaces 1 through 3 in this example represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

## Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Enable OSPF on DeviceA, DeviceB, DeviceC, and DeviceD (except 10.2.1.1/30) and specify the same area for all OSPF interfaces.
2. Set up IBGP connections between DeviceA, DeviceB, DeviceC, and DeviceD (except 10.2.1.1/30).
3. Configure the OSPF cost on DeviceC.
4. Set up EBGP connections between DeviceD and DeviceE.
5. Configure BGP to import direct routes and OSPF processes on DeviceD.
6. Configure BGP on DeviceE.

## Data Preparation

To complete the configuration, you need the following data:

- Data of DeviceA, including the router ID (1.1.1.1), number of the AS to which DeviceA belongs (10), OSPF process ID (1), network segment addresses of area 0 (10.1.1.0/30 and 10.1.2.0/30), and loopback0 IP address (1.1.1.1/32)
- Data of DeviceB, including the router ID (2.2.2.2), number of the AS to which DeviceB belongs (10), OSPF process ID (1), network segment addresses of area 0 (10.1.1.0/30 and 10.1.3.0/30), and loopback0 IP address (2.2.2.2/32)

- Data of DeviceC, including the router ID (3.3.3.3), number of the AS to which DeviceC belongs (10), OSPF process ID (1), network segment addresses of area 0 (10.1.2.0/30 and 10.1.4.0/30), and loopback0 IP address (3.3.3.3/32)
- Data of DeviceD, including the router ID (4.4.4.4), number of the AS to which DeviceD belongs (10), OSPF process ID (1), network segment addresses of area 0 (10.1.3.0/30 and 10.1.4.0/30), and loopback0 IP address (4.4.4.4/32)
- Data of DeviceE, including the router ID (5.5.5.5), number of the AS to which DeviceE belongs (20), and loopback0 IP address (5.5.5.5/32)

## Procedure

- Step 1** Assign an IP address to each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure basic OSPF functions. For details, see [Example for Configuring Basic OSPF Functions](#).
- Step 3** Set up IBGP connections.

# Configure DeviceA.

As shown in the routing table, DeviceB learns the route to 10.3.1.0 through BGP, and the outbound interface is GE 2/0/0. The routes to 10.1.2.0 and 10.1.4.0 can be learned through OSPF. The costs of these routes are both 2.

**Step 6** Enable OSPF-BGP synchronization on DeviceB.

```
[~DeviceB] ospf 1
[*DeviceB-ospf-1] stub-router on-startup
[*DeviceB-ospf-1] commit
```

**Step 7** Verify the configuration.

```
Restart router DeviceB.
```

NOTE

Exercise caution when running this command because it may lead to a temporary network crash. In addition, save the configuration file of the router before restarting it.

```
<DeviceB> reboot
System will reboot! Continue?[Y/N] y
```

```
Display the routing table on DeviceA. As shown in the routing table, BGP learns the route to 10.3.1.0, and the outbound interface is GigabitEthernet2/0/0.
```

```
[~DeviceA] display ip routing-table

## Example for Configuring Routing Loop Detection for Routes Imported from BGP to OSPF

This section describes how to configure routing loop detection for routes imported from BGP to OSPF.

### Networking Requirements

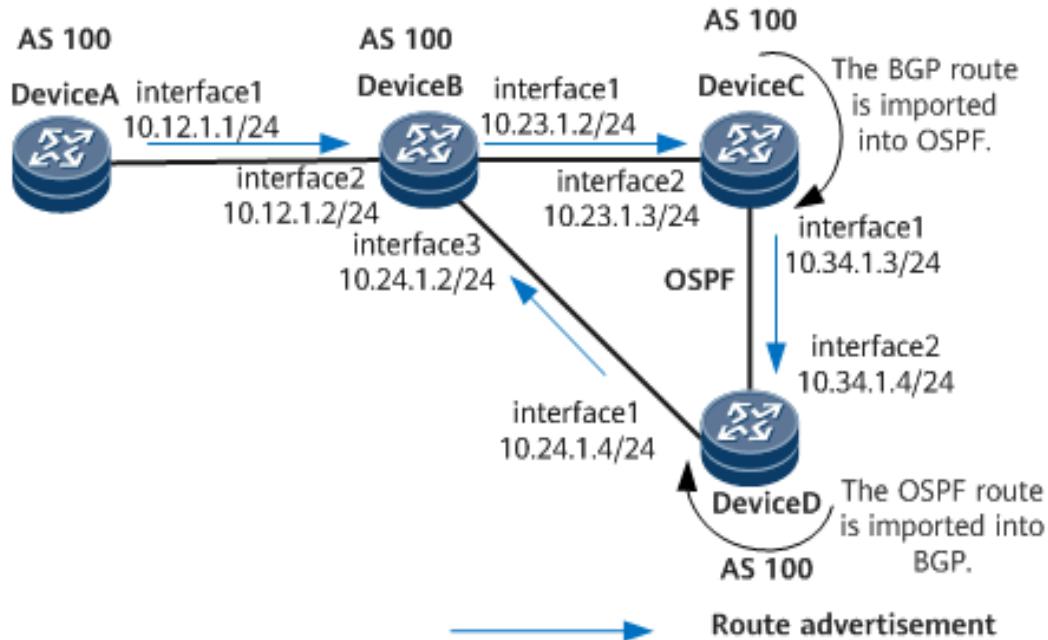

On the live network, OSPF routes can be imported to a BGP process for redistribution. In such a scenario, routing policies are usually configured on multiple devices to prevent routing loops. If routing policies are incorrectly configured on the devices that import routes, routing loops may occur. To prevent this problem, configure routing loop detection for the routes imported to OSPF.

On the network shown in [Figure 1-137](#), IBGP peer relationships are established between DeviceA and DeviceB, between DeviceB and DeviceC, between DeviceC and DeviceD, and between DeviceB and DeviceD; an OSPF process is configured on DeviceC and DeviceD. OSPF is configured to import BGP routes on DeviceC, and BGP is configured to import OSPF routes on DeviceD.

**Figure 1-137** Routing loop detection for routes imported from BGP to OSPF

#### NOTE

In this example, interface1, interface2, and interface3 represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

## Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure IP addresses for interfaces on each device.
2. Enable OSPF and BGP, and configure basic OSPF and BGP functions.
3. Configure route import to construct a routing loop.
4. Check whether a routing loop occurs.
5. Enable routing loop detection to check whether the routing loop is eliminated.

## Procedure

### Step 1 Assign an IP address to each interface.

DeviceA is used as an example.

```
<DeviceA> system-view
[~DeviceA] interface gigabitethernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] ip address 10.12.1.1 24
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] commit
```

The configurations of other devices are similar to those of DeviceA. For configuration details, see [Configuration Files](#) in this section.

In addition, configure a static route on DeviceA to simulate a looped route.

```
[~DeviceA] ip route-static 10.0.0.0 255.255.255.255 NULL0
[*DeviceA] commit
```

**Step 2** Enable OSPF and BGP, and configure basic OSPF and BGP functions to implement intra-AS communication.

```
Enable BGP on DeviceA, and establish an IBGP peer relationship between
DeviceA and DeviceB.
```

```
[~DeviceA] bgp 100
[*DeviceA-bgp] router-id 1.11.1.1
[*DeviceA-bgp] peer 10.12.1.2 as-number 100
[*DeviceA-bgp] ipv4-family unicast
[*DeviceA-bgp-af-ipv4] peer 10.12.1.2 enable
[*DeviceA-bgp] quit
[*DeviceA] commit
```

```
Enable BGP on DeviceB and establish IBGP peer relationships between DeviceB
and DeviceA, between DeviceB and DeviceC, and between DeviceB and DeviceD.
```

```
[~DeviceB] bgp 100
[*DeviceB-bgp] router-id 2.22.2.2
[*DeviceB-bgp] peer 10.12.1.1 as-number 100
[*DeviceB-bgp] peer 10.23.1.3 as-number 100
[*DeviceB-bgp] peer 10.24.1.4 as-number 100
[*DeviceB-bgp] ipv4-family unicast
[*DeviceB-bgp-af-ipv4] peer 10.12.1.1 enable
[*DeviceB-bgp-af-ipv4] peer 10.23.1.3 enable
[*DeviceB-bgp-af-ipv4] peer 10.24.1.4 enable
[*DeviceB-bgp-af-ipv4] peer 10.23.1.3 reflect-client
[*DeviceB-bgp] quit
[*DeviceB] commit
```

```
Enable BGP on DeviceC, and establish an IBGP peer relationship between
DeviceC and DeviceB.
```

```
[~DeviceC] bgp 100
[*DeviceC-bgp] router-id 3.33.3.3
[*DeviceC-bgp] peer 10.23.1.2 as-number 100
[*DeviceC-bgp] ipv4-family unicast
[*DeviceC-bgp-af-ipv4] peer 10.23.1.2 enable
[*DeviceC-bgp] quit
[*DeviceC] commit
```

```
Enable BGP on DeviceD, and establish an IBGP peer relationship between
DeviceD and DeviceB.
```

```
[~DeviceD] bgp 100
[*DeviceD-bgp] router-id 4.44.4.4
[*DeviceD-bgp] peer 10.24.1.2 as-number 100
[*DeviceD-bgp] ipv4-family unicast
[*DeviceD-bgp-af-ipv4] peer 10.24.1.2 enable
[*DeviceD-bgp] quit
[*DeviceD] commit
```

```
Configure OSPF on DeviceC and DeviceD. DeviceC is used as an example.
```

```
[~DeviceC] ospf 1 router-id 3.33.3.3
[*DeviceC-ospf-1] area 0
[*DeviceC-ospf-1-area-0.0.0.0] network 10.34.1.0 0.0.0.255
[*DeviceC-ospf-1-area-0.0.0.0] quit
[*DeviceC-ospf-1] quit
[*DeviceC] commit
```

**Step 3** Configure route import.

```
Configure OSPF on DeviceC to import BGP routes.
```

```
[~DeviceC] ospf 1 router-id 3.33.3.3
[*DeviceC-ospf-1] import-route bgp permit-ibgp
[*DeviceC-ospf-1] quit
[*DeviceC] commit
```

# Configure BGP on DeviceD to import OSPF routes.

```
[~DeviceD] bgp 100
[*DeviceD-bgp] ipv4-family unicast
[*DeviceD-bgp-af-ipv4] import-route ospf 1
[*DeviceD-bgp] quit
[*DeviceD] commit
```

**Step 4** View the routing table on each device to check whether a routing loop occurs.

# Check BGP peer information on DeviceB.

```
[~DeviceB] display bgp peer
BGP local router ID : 2.22.2.2
Local AS number : 100
Total number of peers : 3 Peers in established state : 3

Peer V AS MsgRcvd MsgSent OutQ Up/Down State PrefRcv
10.12.1.1 4 100 453 458 0 06:30:47 Established 1
10.23.1.3 4 100 452 458 0 06:30:46 Established 0
10.24.1.4 4 100 451 457 0 06:29:39 Established 3
```

# Check OSPF neighbor information on DeviceC.

```
[~DeviceC] display ospf peer
(M) Indicates MADJ neighbor

OSPF Process 1 with Router ID 3.33.3.3
Neighbors

Area 0.0.0 interface 10.34.1.3 (GigabitEthernet1/0/0)'s neighbors
Router ID: 4.44.4.4 Address: 10.34.1.4

```

# Check OSPF neighbor information on DeviceD.

```
[~DeviceD] display ospf peer
(M) Indicates MADJ neighbor

OSPF Process 1 with Router ID 4.44.4.4
Neighbors

Area 0.0.0 interface 10.34.1.4 (GigabitEthernet2/0/0)'s neighbors
Router ID: 3.33.3.3 Address: 10.34.1.3
State: Full Mode:Nbr is Slave Priority: 1
DR: 10.34.1.4 BDR: 10.34.1.3 MTU: 0
Dead timer due in 32 sec
Retrans timer interval: 5
Neighbor is up for 06h28m25s
Neighbor Up Time : 2021-08-27 02:59:32
Authentication Sequence: [0]
```

The preceding command outputs show that BGP peer relationships and OSPF neighbor relationships have been established between the devices.

# Check the BGP routing table on DeviceB.

```
[~DeviceB] display bgp routing-table 10.0.0.0
BGP local router ID : 2.22.2.2
Local AS number : 100
Paths: 2 available, 1 best, 1 select, 0 best-external, 0 add-path
BGP routing table entry information of 10.0.0.0/32:
RR-client route.
From: 10.24.1.4 (4.44.4.4)
Route Duration: 0d00h00m52s
Relay IP Nexthop: 10.24.1.4
Relay IP Out-Interface: GigabitEthernet1/0/0
Original nexthop: 10.24.1.4
Qos information : 0x0
AS-path Nil, origin incomplete, MED 1, localpref 100, pref-val 0, valid, internal, best, select, pre 255
Advertised to such 3 peers:
 10.23.1.3
 10.24.1.4
 10.12.1.1

BGP routing table entry information of 10.0.0.0/32:
From: 10.12.1.1 (1.11.1.1)
Route Duration: 0d22h53m22s
Relay IP Nexthop: 10.12.1.1
Relay IP Out-Interface: GigabitEthernet2/0/0
Original nexthop: 10.12.1.1
Qos information : 0x0
AS-path 10, origin incomplete, MED 0, localpref 100, pref-val 0, valid, internal, pre 255, not preferred for
AS-Path
Not advertised to any peer yet
```

The preceding command output shows that DeviceB has learned the BGP route distributed by DeviceD.

# Check the BGP routing table of DeviceC.

```
[~DeviceC] display bgp routing-table 10.0.0.0
BGP local router ID : 3.33.3.3
Local AS number : 100
Paths: 1 available, 1 best, 1 select, 0 best-external, 0 add-path
BGP routing table entry information of 10.0.0.0/32:
From: 10.23.1.2 (2.22.2.2)
Route Duration: 0d07h12m30s
Relay IP Nexthop: 0.0.0.0
Relay IP Out-Interface: NULL0
Original nexthop: 10.12.1.1
Qos information : 0x0
AS-path 10, origin incomplete, MED 0, localpref 100, pref-val 0, valid, internal, best, select, pre 255
Originator: 1.11.1.1
Cluster list: 2.22.2.2
Not advertised to any peer yet
```

The preceding command output shows that DeviceC has learned the BGP route distributed by DeviceB.

# Check the routing table of DeviceD.

```
[~DeviceD] display ospf routing 10.0.0.0
OSPF Process 1 with Router ID 4.44.4.4

Destination : 10.0.0.0/32
AdverRouter : 3.33.3.3 Tag : 1
Cost : 1 Type : Type2
NextHop : 10.34.1.3 Interface : GigabitEthernet2/0/0
Priority : Medium Age : 01h31m18s
```

The preceding command output shows that DeviceD has learned the OSPF route distributed by DeviceC.

This means that a routing loop occurs among DeviceB, DeviceC, and DeviceD.

**Step 5** Enable routing loop detection on each device.

# Enable routing loop detection for routes imported to OSPF and BGP. DeviceA is used as an example.

```
[~DeviceA] route loop-detect ospf enable
[*DeviceA] route loop-detect bgp enable
[*DeviceA] commit
```

 **NOTE**

In the case of inter-protocol route import, if a routing protocol with a higher preference detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower preference is used for such processing, this route competes with the originally imported route during route selection. In this case, the routing loop can be eliminated. OSPF has a higher preference than BGP. Therefore, to eliminate the routing loop, BGP needs to reduce the preference of the corresponding route.

**Step 6** Check whether the routing loop is eliminated.

# Check the BGP routing table on DeviceB.

```
[~DeviceB] display bgp routing-table 10.0.0.0
BGP local router ID : 2.22.2.2
Local AS number : 100
Paths: 1 available, 1 best, 1 select, 0 best-external, 0 add-path
BGP routing table entry information of 10.0.0.0/32:
From: 10.12.1.1 (1.1.1.1)
Route Duration: 1d00h10m02s
Relay IP Nexthop: 10.12.1.1
Relay IP Out-Interface: GigabitEthernet2/0/0
Original nexthop: 10.12.1.1
Qos information : 0x0
AS-path 10, origin incomplete, MED 0, localpref 100, pref-val 0, valid, internal, best, select, pre 255
Advertised to such 2 peers:
 10.23.1.3
 10.24.1.4
```

The preceding command output shows that DeviceB has learned the route distributed by DeviceA and that DeviceB no longer prefers the route distributed by DeviceD. This means that the routing loop among DeviceB, DeviceC, and DeviceD is eliminated.

**----End**

## Example for Configuring OSPF Delay Reporting to BGP-LS

Border Gateway Protocol-Link State (BGP-LS) can be used to summarize topology information collected by IGPs and send the information to the upper-layer controller.

## Networking Requirements

BGP-LS is a new method of collecting network topology information. The topology information discovered by IGPs is summarized and reported to an upper-layer controller through BGP. With powerful routing capabilities of BGP, BGP-LS has the following advantages:

- Lowers the requirements on the controller's computing and IGP capabilities.
- Facilitates route selection and computation on the controller by using BGP to summarize process or AS topology information and report the complete information to the controller.
- Requires only one routing protocol (BGP) to report topology information to the controller.

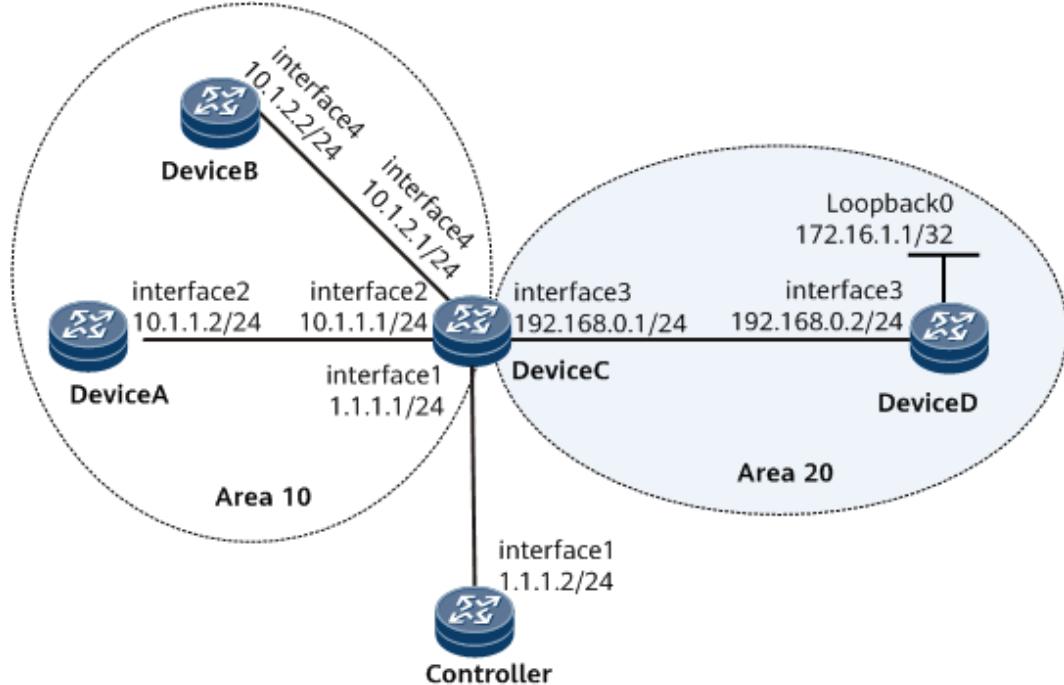

In [Figure 1-138](#), DeviceC is connected to the controller and reports topology information to the controller. DeviceA, DeviceB, DeviceC, and DeviceD use OSPF to

implement IP network interworking. The two interfaces connecting DeviceC and DeviceD belong to area 20, and the interfaces connecting DeviceA, DeviceB, and DeviceC belong to area 10.

**Figure 1-138** Configuring BGP-LS

 **NOTE**

In this example, interface1, interface2, interface3, and interface4 represent GigabitEthernet1/0/1, GigabitEthernet1/0/2, GigabitEthernet1/0/3, and GigabitEthernet1/0/4, respectively.

## Precautions

To improve security, you are advised to deploy BGP security measures. For details, see "Configuring BGP Security." Keychain authentication is used as an example. For details, see "Example for Configuring BGP Keychain."

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure an IP address for each interface on each router.
2. Configure basic OSPF functions.
3. Deploy BGP-LS on DeviceC and the controller.
4. Configure DeviceA and DeviceC as the TWAMP sender and receiver, respectively.
5. Configure delay advertisement on DeviceA.

## Data Preparation

To complete the configuration, you need the following data:

- IP addresses and areas of interfaces on DeviceA, DeviceB, DeviceC, and DeviceD
- BGP-LS ID in OSPF on DeviceC
- BGP AS numbers, BGP-LS domain AS numbers, and BGP-LS domain IDs of DeviceC and the controller

## Procedure

**Step 1** Assign an IP address to each interface on each router. For configuration details, see [Configuration Files](#) in this section.

**Step 2** Configure basic OSPF functions.

# Configure DeviceA.

## Example for Configuring OSPF Multi-Area Adjacency

This section provides an example for configuring OSPF multi-area adjacency, which includes configuration of enabling OSPF on each device, physical interface, and OSPF multi-area adjacency interface.

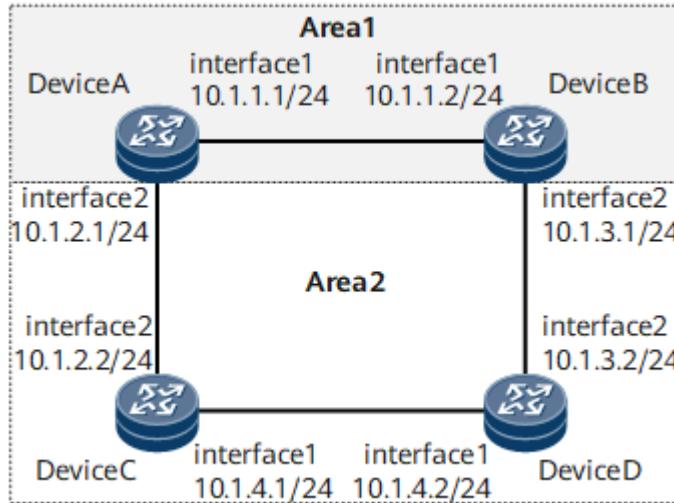

## Networking Requirements

In [Figure 1-139](#), all routers run OSPF, and the AS consists of two areas: area 1 and area 2. The link between DeviceA and DeviceB in area 1 is a high-speed link. Because intra-area links take precedence over inter-area links during OSPF route selection, traffic from DeviceA to DeviceB in area 2 is forwarded along the low-speed link of DeviceA->DeviceC->DeviceD->DeviceB, even though high-speed link between DeviceA and DeviceB exists. It is required that traffic from DeviceA to DeviceB in area 2 be forwarded along the high-speed link between DeviceA and DeviceB. In this case, configure OSPF multi-area adjacency on DeviceA and DeviceB and add their multi-area adjacency interfaces to area 2.

**Figure 1-139** Networking for configuring OSPF multi-area adjacency

 **NOTE**

Interfaces 1 and 2 in this example represent GE1/0/0 and GE2/0/0, respectively.

## Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Enable OSPF on each router.
2. Enable OSPF on physical interfaces.
3. Enable OSPF on multi-area adjacency interfaces.

## Data Preparation

To complete the configuration, you need the following data:

- OSPF process ID: 1
- OSPF areas: area 1 and area 2

## Procedure

**Step 1** Configure an IP address for each interface. The configuration details are not provided here.

**Step 2** Configure basic OSPF functions.

```
Configure DeviceA.
```

```
[~DeviceA] ospf 1
[*DeviceA-ospf-1] area 1
[*DeviceA-ospf-1-area-0.0.0.1] quit
[*DeviceA-ospf-1] quit

[*DeviceC-GigabitEthernet2/0/0] ospf enable 1 area 2
[*DeviceC-GigabitEthernet2/0/0] quit
[*DeviceC] commit
```

# Configure DeviceD.

```
[~DeviceD] ospf 1
[*DeviceD-ospf-1] area 2
[*DeviceD-ospf-1-area-0.0.0.2] quit
[*DeviceD-ospf-1] quit
[*DeviceD] interface gigabitethernet 1/0/0
[*DeviceD-GigabitEthernet1/0/0] ospf enable 1 area 2
[*DeviceD-GigabitEthernet1/0/0] quit
[*DeviceD] interface gigabitethernet 2/0/0
[*DeviceD-GigabitEthernet2/0/0] ospf enable 1 area 2
[*DeviceD-GigabitEthernet2/0/0] quit
[*DeviceD] commit
```

# Run the **display ospf peer brief** command to check brief information about OSPF neighbors. DeviceA is used as an example. The following command output shows that the OSPF neighbor relationships between DeviceA and DeviceB and between DeviceA and DeviceC are established.

```
[~DeviceA] display ospf peer brief
(M) Indicates MADJ neighbor
```

```
OSPF Process 1 with Router ID 1.1.1.1
Peer Statistic Information
Total number of peer(s): 2
Peer(s) in full state: 2

Area Id Interface Neighbor id State
0.0.0.1 GigabitEthernet1/0/0 10.1.1.2 Full
0.0.0.2 GigabitEthernet2/0/0 10.1.1.1 Full
```

# Run the **display ip routing-table** command to check information about the IP routing table. DeviceA is used as an example. The following command output shows that the outbound interface of the route destined for 1.1.1.1 is GigabitEthernet 2/0/0.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Destinations : 13 Routes : 13
Destination/Mask Proto Pre Cost Flags NextHop Interface
1.1.1.1/32 OSPF 10 3 D 10.1.2.2 GigabitEthernet2/0/0
10.1.1.0/24 Direct 0 0 D 10.1.1.1 GigabitEthernet1/0/0
10.1.1.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
10.1.1.255/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
10.1.2.0/24 Direct 0 0 D 10.1.2.1 GigabitEthernet2/0/0
10.1.2.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet2/0/0
10.1.2.255/32 Direct 0 0 D 127.0.0.1 GigabitEthernet2/0/0
10.1.3.0/24 OSPF 10 3 D 10.1.2.2 GigabitEthernet2/0/0
10.1.4.0/24 OSPF 10 2 D 10.1.2.2 GigabitEthernet2/0/0
127.0.0.0/8 Direct 0 0 D 127.0.0.1 InLoopBack0
127.0.0.1/32 Direct 0 0 D 127.0.0.1 InLoopBack0

255.255.255.255/32 Direct 0 0 D 127.0.0.1 InLoopBack0
```

The preceding command output shows that traffic from routerA to routerB in area 2 is forwarded along the low-speed link of routerA -> routerC -> routerD -> routerB.

### Step 3 Enable OSPF on multi-area adjacency interfaces.

# Configure DeviceA.

```
[~DeviceA] interface gigabitethernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] ospf enable multi-area 2
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] commit
```

# Configure DeviceB.

```
[~DeviceB] interface gigabitethernet 1/0/0
[*DeviceB-GigabitEthernet1/0/0] ospf enable multi-area 2
[*DeviceB-GigabitEthernet1/0/0] quit
[*DeviceB] commit
```

### Step 4 Verify the configuration.

# Run the **display ospf peer brief** command to check brief information about OSPF neighbors. DeviceA is used as an example. The following command output shows that the OSPF neighbor relationships between DeviceA and DeviceB and between DeviceA and DeviceC are established and that an OSPF multi-area adjacency is established between DeviceA and DeviceB.

```
[~DeviceA] display ospf peer brief
```

(M) Indicates MADJ neighbor

## Example for Configuring an OSPF Sham Link

This section provides an example for configuring an OSPF sham link so that traffic between sites of the same VPN in the same OSPF area is forwarded through the OSPF intra-area route over the BGP/MPLS IP VPN backbone network.

## Networking Requirements

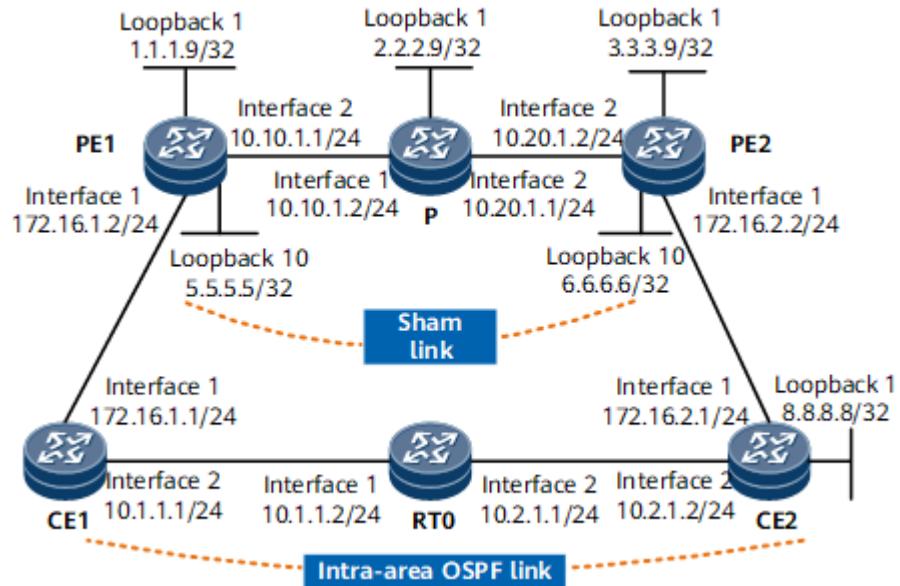

In [Figure 1-140](#), CE1 and CE2 reside in the same OSPF area, belong to VPN1, and are connected to PE1 and PE2, respectively. In this example, the cost of each link is 1.

It is required that OSPF run between each CE and its connected PE and the VPN traffic between CE1 and CE2 be forwarded over the MPLS backbone network.

**Figure 1-140** Networking for configuring an OSPF sham link

 NOTE

Interfaces 1 and 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

## Precautions

To improve security, OSPF area authentication or interface authentication is recommended. For details, see "Improving OSPF Network Security". OSPF area authentication is used as an example. For details, see Example for Configuring Basic OSPF Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure an MP-IBGP peer relationship between PEs and configure OSPF between each CE and its connected PE.
2. Create a VPN instance on each PE and bind the VPN instance to the interface connected to the corresponding CE.
3. Create an OSPF sham link between PEs.
4. Adjust the cost of forwarding interfaces over the user network to ensure that the cost of the OSPF route used to forward the traffic over the user network is greater than that of the sham link.

## Data Preparation

To complete the configuration, you need the following data:

- MPLS LSR IDs of the PEs and P
- VPN instance name, RD, and VPN target of each PE
- Data used to configure OSPF (The OSPF process running on the backbone network, the OSPF process running on the user network, and the OSPF process connecting each PE to the corresponding CE are different.)
- Cost of the sham link and the cost of the OSPF route used to forward the traffic over the user network

## Procedure

### Step 1 Configure OSPF on the user network.

Configure OSPF on CE1, RT0, and CE2 and advertise network segments of their interfaces.

# Configure CE1.

[*PE2-bgp-vpn1] import-route ospf 100
[*PE2-bgp-vpn1] quit
[*PE2-bgp] quit
[*PE2] commit
```

After completing the configurations, run the **display ip routing-table vpn-instance** command on a PE. You may find that the route to the remote CE is an OSPF route over the user network rather than the BGP route over the backbone network.

The following example uses the command output on PE1.

```
<PE1> display ip routing-table vpn-instance vpn1
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: vpn1
Destinations : 5 Routes : 5
Destination/Mask Proto Pre Cost Flags NextHop Interface
 10.1.0.0/24 OSPF 10 2 D 172.16.1.1 GigabitEthernet1/0/0
 10.2.1.0/24 OSPF 10 3 D 172.16.1.1 GigabitEthernet1/0/0
 172.16.1.0/24 Direct 0 0 D 172.16.1.2 GigabitEthernet1/0/0
 172.16.1.2/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
 172.16.2.0/24 OSPF 10 4 D 172.16.1.1 GigabitEthernet1/0/0
```

#### Step 4 Configure a sham link.

To ensure that VPN traffic is forwarded over the MPLS backbone network, ensure that the cost of the sham link is smaller than that of the OSPF route used to forward the traffic over the user network when configuring the sham link. In most cases, you need to change the cost of the interfaces on the user network to ensure that the cost of the OSPF route used to forward the traffic over the user network is greater than that of the sham link.

# Configure CE1.

```
[~CE1] interface GigabitEthernet2/0/0
[~CE1-GigabitEthernet2/0/0] ospf cost 10
[*CE1-GigabitEthernet2/0/0] quit
[*CE1] commit
```

# Configure CE2.

```
[~CE2] interface GigabitEthernet2/0/0
[~CE2-GigabitEthernet2/0/0] ospf cost 10
[*CE2-GigabitEthernet2/0/0] quit
[*CE2] interface loopback 1
[*CE2-LoopBack1] ip address 8.8.8.8 32
[*CE2-LoopBack1] ospf enable 1 area 0
[*CE2-LoopBack1] quit
[*CE2] commit
```

# Configure PE1.

```
[~PE1] interface loopback 10
[*PE1-LoopBack10] ip binding vpn-instance vpn1
[*PE1-LoopBack10] ip address 5.5.5.5 32
[*PE1-LoopBack10] quit
[*PE1] ospf 100 router-id 11.11.11.11
[*PE1-ospf-100] area 0
[*PE1-ospf-100-area-0.0.0.0] sham-link 5.5.5.5 6.6.6.6 cost 1
[*PE1-ospf-100-area-0.0.0.0] quit
[*PE1-ospf-100] quit
[*PE1] commit
```

# Configure PE2.

```
[~PE2] interface loopback 10
[*PE2-LoopBack10] ip binding vpn-instance vpn1
[*PE2-LoopBack10] ip address 6.6.6.6 32
[*PE2-LoopBack10] quit
[*PE2] ospf 100 router-id 22.22.22.22
[*PE2-ospf-100] area 0
[*PE2-ospf-100-area-0.0.0.0] sham-link 6.6.6.6 5.5.5.5 cost 1
[*PE2-ospf-100-area-0.0.0.0] quit
[*PE2-ospf-100] quit
[*PE2] commit
```

### Step 5 Verify the configuration.

After completing the configurations, run the **display ip routing-table vpn-instance** command again on the PE. You may find that the route to the remote CE becomes the BGP route over the backbone network and a route to the destination IP address of the sham link also exist in the routing table.

The following example uses the command output on PE1.

```
<PE1> display ip routing-table vpn-instance vpn1
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: vpn1
Destinations : 10 Routes : 10
Destination/Mask Proto Pre Cost Flags NextHop Interface
 5.5.5.5/32 Direct 0 0 D 127.0.0.1 LoopBack10
 6.6.6.6/32 IBGP 255 0 RD 3.3.3.9 GigabitEthernet2/0/0
 8.8.8.8/32 IBGP 255 2 RD 3.3.3.9 GigabitEthernet2/0/0
 10.1.1.0/24 OSPF 10 11 D 172.16.1.1 GigabitEthernet1/0/0
 10.2.1.0/24 OSPF 10 12 D 172.16.1.1 GigabitEthernet1/0/0
 172.16.1.0/24 Direct 0 0 D 172.16.1.2 GigabitEthernet1/0/0
 172.16.1.2/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
 172.16.1.255/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
 172.16.2.0/24 IBGP 255 0 RD 3.3.3.9 GigabitEthernet2/0/0
 255.255.255.255/32 Direct 0 0 D 127.0.0.1 InLoopBack0
```

Run the **display ip routing-table** command on a CE. You may find that the cost of the OSPF route to the remote CE becomes 3 and the next hop is the IP address of the connected PE interface. The next hop indicates that the VPN traffic to the remote end is forwarded over the backbone network.

The following example uses the command output on CE1.

```
<CE1> display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Destinations : 15 Routes : 15
Destination/Mask Proto Pre Cost Flags NextHop Interface

 172.16.2.0/24 OSPF 10 3 D 172.16.1.2 GigabitEthernet1/0/0
 255.255.255.255/32 Direct 0 0 D 127.0.0.1 InLoopBack0
```

#### NOTE

Cost (3) of the OSPF route from CE1 to CE2 = Cost (1) of the link from CE1 to PE1 + Cost (1) of the sham link + Cost (1) of the link from PE2 to CE2

Run the **tracert** command and you may find that the next hop for CE1 to send data to CE2 is the IP address of PE1's GE 1/0/0. The next hop indicates that the VPN traffic to the remote end is forwarded over the backbone network.

```
<CE1> tracert 172.16.2.1
traceroute to 172.16.2.1(172.16.2.1), max hops: 30 ,packet length: 40,press CTRL_C to break
1 172.16.1.2 131 ms 2 ms 1 ms
2 10.10.1.2 475 ms 4 ms 4 ms
3 172.16.2.2 150 ms 3 ms 4 ms
4 172.16.2.1 76 ms 3 ms 5 ms
<CE1> tracert 10.2.1.2
traceroute to 10.2.1.2(10.2.1.2), max hops: 30 ,packet length: 40,press CTRL_C to break
1 10.1.1.2 60 ms 1 ms 1 ms
2 10.2.1.2 12 ms 2 ms 2 ms
```

Run the **display ospf sham-link** command on a PE to check whether the sham link is established.

The following example uses the command output on PE1.

```
<PE1> display ospf sham-link
OSPF Process 100 with Router ID 11.11.11.11
Area NeighborID Source-IP Destination-IP State Cost
0.0.0.0 22.22.22.22 5.5.5.5 6.6.6.6 P-2-P 1
```

Run the **display ospf sham-link area** command. The following command output shows that the OSPF neighbor relationship is in Full state.

```
<PE1> display ospf sham-link area 0
OSPF Process 100 with Router ID 11.11.11.11
Sham-Link: 5.5.5.5 --> 6.6.6.6
NeighborID: 22.22.22.22, State: Full, GR status: Normal
Area: 0.0.0
Cost: 1 , State: P-2-P , Type: Sham
Timers: Hello 10 , Dead 40 , Retransmit 5 , Transmit Delay 1
```

Run the **display ospf routing** command on a CE. The following command output shows that the route to the remote CE is an intra-area route.

```
<CE1> display ospf routing
OSPF Process 1 with Router ID 10.1.1.1

## 1.1.5 OSPFv3 Configuration

### 1.1.5.1 OSPFv3 Description

#### 1.1.5.1.1 Introduction to OSPFv3

##### Definition

Open Shortest Path First (OSPF) is a link-state Interior Gateway Protocol (IGP) developed by the Internet Engineering Task Force (IETF).

OSPF version 2 (OSPFv2) is intended for IPv4, and OSPF version 3 (OSPFv3) is intended for IPv6.

- OSPFv3 is short for OSPF version 3.
- OSPFv3 runs over IPv6.
- OSPFv3 is an enhanced version of OSPFv2 but is an independent routing protocol.

##### Purpose

OSPFv3 is an extension of OSPF for support of IPv6.

### 1.1.5.1.2 Understanding OSPFv3

#### OSPFv3 Fundamentals

Running on IPv6, OSPFv3 is an independent routing protocol that is developed on the basis of OSPFv2.

- OSPFv3 and OSPFv2 are the same in terms of the working principles of the Hello packet, state machine, link-state database (LSDB), flooding, and route calculation.
- OSPFv3 packets are encapsulated into IPv6 packets and can be transmitted in unicast or multicast mode.

#### OSPFv3 Packet Types

| Packet Type                              | Function                                                                                                                                                      |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hello packet                             | Hello packets are sent periodically to discover and maintain OSPFv3 neighbor relationships.                                                                   |
| Database Description (DD) packet         | Such packets contain the summary of the local LSDB and are used for LSDB synchronization between two devices.                                                 |
| Link State Request (LSR) packet          | LSR packets are sent to the neighbor to request the required LSAs.<br>An OSPFv3 device sends LSR packets to its neighbor only after they exchange DD packets. |
| Link State Update (LSU) packet           | LSU packets carry the LSAs required by neighbors.                                                                                                             |
| Link State Acknowledgment (LSAck) packet | LSAck packets acknowledge the receipt of an LSA.                                                                                                              |

#### LSA Types

OSPFv3 encapsulates routing information into LSAs for transmission. [Table 1-52](#) describes LSAs and their functions.

**Table 1-52** LSAs and their functions

| LSA Type            | Description                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router-LSA (Type 1) | Describes the link status and link cost of a device, is generated by the device for the area in which each OSPFv3 interface resides, and is advertised in the area. |

| LSA Type                       | Description                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Network-LSA (Type 2)           | Describes the local link status. Network-LSAs are generated by a designated router (DR) and advertised in the area to which the DR belongs.                                                                                                                                                                                                                   |
| Inter-Area-Prefix-LSA (Type 3) | Describes routes to a specific network segment in an area. Inter-Area-Prefix-LSAs are generated by an ABR and advertised to related areas.                                                                                                                                                                                                                    |
| Inter-Area-Router-LSA (Type 4) | Describes routes to an Autonomous System Boundary Router (ASBR). Inter-Area-Router-LSAs are generated by an ABR and advertised to all related areas except the area to which the ASBR belongs.                                                                                                                                                                |
| AS-external-LSA (Type 5)       | Originated by ASBRs, and advertised to all areas, excluding stub areas and NSSAs. Each AS-external-LSA describes a route to another AS.                                                                                                                                                                                                                       |
| NSSA LSA (Type 7)              | Describes routes to another AS. It is generated by an ASBR and advertised in NSSAs only.                                                                                                                                                                                                                                                                      |
| Link-LSA (Type 8)              | Describes the link-local address and IPv6 address prefix associated with the link and the link option set in the network LSA. Link-LSAs are transmitted only on the link.                                                                                                                                                                                     |
| Intra-Area-Prefix-LSA (Type 9) | Each device or DR generates one or more intra-area prefix LSAs and transmits it in the local area. <ul style="list-style-type: none"> <li>• Such LSAs generated by a device describe the IPv6 address prefixes associated with router-LSAs.</li> <li>• An LSA generated on a DR describes the IPv6 prefix address associated with the network-LSA.</li> </ul> |
| Intra-Area-TE-LSA (Type 10)    | Each device that supports TE services generates LSAs of this type to advertise its own TE information and link-related TE information within the area to which the device belongs.                                                                                                                                                                            |

| LSA Type                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Grace-LSA (Type 11)                          | During the GR process, each device that supports the GR service advertises this type of LSA to each interface. The LSA is advertised by specified interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| OSPFv3 Router Information (RI) LSA (Type 12) | <p>LSAs of this type are generated when a device needs to advertise its extension information. LSAs of this type are classified into the following types:</p> <ul style="list-style-type: none"><li>• Area Router Information LSA:<br/>LSAs of this type are transmitted in the area to which the device belongs when TLVs such as SRv6 Capabilities TLV, SR-Algorithm TLV, SRv6 NODE MSD TLV, and Dynamic Hostname TLV need to be advertised.</li><li>• AS Router Information LSA<br/>LSAs of this type are transmitted in all areas when TLVs such as Dynamic Hostname TLV need to be advertised.</li></ul> |
| E-Router-LSA (Type 33)                       | LSAs of this type are generated when a device needs to advertise link extension TLVs, such as the End.X SID Sub-TLV and Local Interface IPv6 Address Sub-TLV. Such LSAs are transmitted in the area to which the device belongs.                                                                                                                                                                                                                                                                                                                                                                              |
| E-AS-External-LSA (Type 37)                  | Describes extended TLV information associated with AS-external routes and are generated by an ASBR and advertised to all areas.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| SRv6 Locator LSA (Type 42)                   | Each SRv6-capable device generates this type of LSA for each area when advertising SRv6 locators. These LSAs are transmitted in each area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Router Types

Figure 1-141 Router types

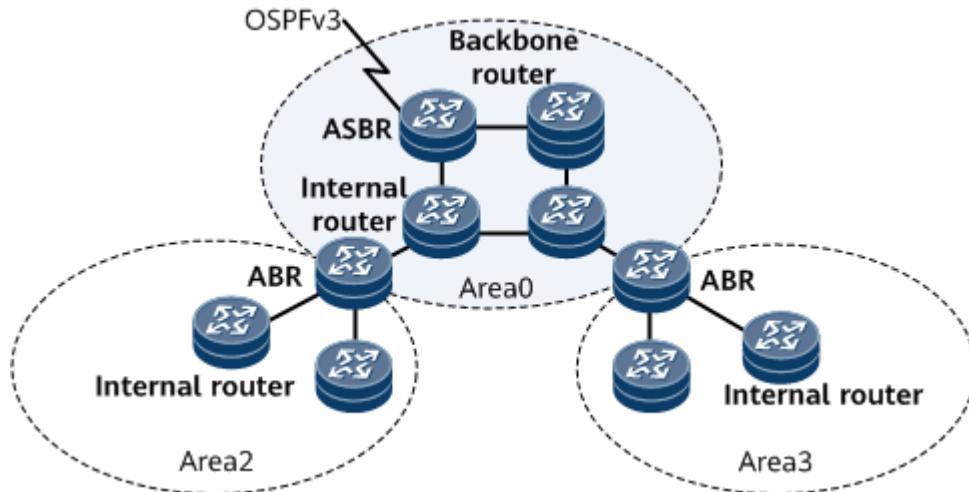

Table 1-53 Router types and descriptions

| Router Type               | Description                                                                                                                                                                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Internal router           | All interfaces on an internal router belong to the same OSPFv3 area.                                                                                                                                                                              |
| Area border router (ABR)  | An ABR belongs to two or more areas, one of which must be the backbone area.<br>An ABR is used to connect the backbone area and non-backbone areas. It can be physically or logically connected to the backbone area.                             |
| Backbone router           | At least one interface on a backbone router belongs to the backbone area.<br>Internal routers in Area 0 and all ABRs are backbone routers.                                                                                                        |
| AS boundary router (ASBR) | An ASBR exchanges routing information with other ASs.<br>An ASBR does not necessarily reside on the border of an AS. It can be an internal router or an ABR. An OSPFv3 device that has imported external routing information will become an ASBR. |

## OSPFv3 Route Types

Inter-area routes and intra-area routes describe the network structure of an AS. External routes describe how to select a route to the destination outside an AS. OSPFv3 classifies the imported AS external routes into Type 1 routes and Type 2 routes.

Table 1-54 lists route types in descending order of priority.

**Table 1-54** Types of OSPFv3 routes

| Route Type            | Description                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Intra Area            | Indicates routes within an area.                                                                                                                                                                                                                                                                                                                             |
| Inter Area            | Indicates routes between areas.                                                                                                                                                                                                                                                                                                                              |
| Type 1 external route | Such routes offer higher reliability, and their costs are approximately the same as those of AS internal routes and are comparable with the costs of routes generated by OSPFv3.<br><br>Cost of a Type 1 external route = Cost of the route from a local router to an ASBR + Cost of the route from the ASBR to the destination of the Type 1 external route |
| Type 2 external route | Such routes have low reliability. Therefore, OSPFv3 considers that the cost of the route from an ASBR to the destination outside the AS is much greater than the cost of any internal route to the ASBR.<br><br>Cost of a Type 2 external route = Cost of the route from the ASBR to the destination of the Type 2 external route                            |

## Area

When a large number of routers run OSPFv3, LSDBs become very large and require a large amount of storage space. Large LSDBs also complicate shortest path first (SPF) computation and may overload routers. As the network scale expands, the probability of network topology changes increases, which causes the network to continuously change. In such cases, large numbers of OSPFv3 packets are transmitted on the network, leading to a decrease in bandwidth utilization efficiency. Each change in the network topology causes all routers on the network to recalculate routes.

OSPFv3 resolves this problem by partitioning an AS into different areas, improving network utilization. An area is regarded as a logical group, and each group is identified by an area ID. A router, not a link, resides at the border of an area. A network segment or link can belong only to one area. An area must be specified for each OSPFv3 interface.

OSPFv3 areas include common areas, stub areas, and NSSAs. **Table 1-55** describes these in more details.

**Table 1-55** Area types

| Area Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Notes                                                                                                                                                                                                                               |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Common area | <p>OSPFv3 areas are common areas by default. Common areas include standard areas and backbone areas.</p> <ul style="list-style-type: none"> <li>• Standard area: transmits intra-area, inter-area, and external routes.</li> <li>• Backbone area: connects to all other OSPFv3 areas and transmits inter-area routes. The backbone area is represented by area 0. Routes between non-backbone areas must be forwarded through the backbone area.</li> </ul>                                                                                                                                                                                                                                                                              | <ul style="list-style-type: none"> <li>• In the backbone area, all devices must be connected.</li> <li>• All non-backbone areas must be connected to the backbone area.</li> </ul>                                                  |
| Stub area   | <p>A stub area is a non-backbone area with only one ABR and generally resides at the border of an AS. The ABR in a stub area does not transmit received AS external routes, which significantly decreases the number of entries in the routing table on the ABR (router) and the amount of routing information to be transmitted. To ensure the reachability of AS external routes, the ABR in the stub area generates a default route and advertises the route to non-ABRs in the stub area.</p> <p>A totally stubby area allows only intra-area routes and ABR-advertised Type 3 default routes to be advertised within the area. The totally stubby area does not allow AS external routes or inter-area routes to be advertised.</p> | <ul style="list-style-type: none"> <li>• The backbone area cannot be configured as a stub area.</li> <li>• An ASBR cannot exist in a stub area. Therefore, AS external routes cannot be advertised within the stub area.</li> </ul> |
| NSSA        | <p>An NSSA is similar to a stub area. An NSSA does not advertise Type 5 LSAs but can import AS external routes. ASBRs in an NSSA generate Type 7 LSAs to carry the information about the AS external routes. The Type 7 LSAs are advertised only within the NSSA. When the Type 7 LSAs reach an ABR in the NSSA, the ABR translates the Type 7 LSAs into Type 5 LSAs and floods them to the entire OSPFv3 domain.</p> <p>A totally NSSA area allows only intra-area routes to be advertised within the area.</p>                                                                                                                                                                                                                         | <ul style="list-style-type: none"> <li>• ABRs in an NSSA advertise Type 3 LSAs carrying a default route within the NSSA. All inter-area routes are advertised by ABRs.</li> </ul>                                                   |

## Network Types Supported by OSPFv3

OSPFv3 classifies networks into the following types (listed in **Table 1-56**) based on link layer protocols.

**Table 1-56** Types of OSPFv3 networks

| Network Type                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Broadcast                            | <p>OSPFv3 considers networks with Ethernet or Fiber Distributed Data Interface (FDDI) as the link layer protocol as broadcast networks by default.</p> <p>On this type of network:</p> <ul style="list-style-type: none"><li>• Hello packets, LSU packets, and LSAck packets are usually transmitted in multicast mode. FF02::5 is an IPv6 multicast address reserved for an OSPFv3 device. FF02::6 is an IPv6 multicast address reserved for an OSPFv3 DR or backup designated router (BDR).</li><li>• DD and LSR packets are transmitted in unicast mode.</li></ul> |
| Non-broadcast Multiple Access (NBMA) | <p>OSPFv3 considers networks with X.25 as the link layer protocol as NBMA networks by default.</p> <p>On an NBMA network, protocol packets, such as Hello packets, DD packets, LSR packets, LSU packets, and LSAck packets are sent in unicast mode.</p>                                                                                                                                                                                                                                                                                                              |
| Point-to-Multipoint (P2MP)           | <p>No network is a P2MP network by default, no matter what type of link layer protocol is used on the network. A non-fully meshed NBMA network can be changed to a P2MP network.</p> <p>On this type of network:</p> <ul style="list-style-type: none"><li>• Hello packets are transmitted in multicast mode using the multicast address FF02::5.</li><li>• Other types of protocol packets, such as DD packets, LSR packets, LSU packets, and LSAck packets are sent in unicast mode.</li></ul>                                                                      |
| Point-to-point (P2P)                 | <p>If the link layer protocol is PPP, LAPB, OSPFv3 defaults the network type to P2P.</p> <p>On such a type of network, protocol packets, such as Hello packets, DD packets, LSR packets, LSU packets, and LSAck packets are sent in multicast mode using the multicast address FF02::5.</p>                                                                                                                                                                                                                                                                           |

## Stub Area

Stub areas are specific areas where ABRs do not flood received AS external routes. In stub areas, routers maintain fewer routing entries and less routing information than the routers in other areas.

Configuring a stub area is optional. Not every area can be configured as a stub area, because a stub area is usually a non-backbone area with only one ABR and is located at the AS border.

To ensure the reachability of the routes to destinations outside an AS, the ABR in the stub area generates a default route and advertises the route to the non-ABRs in the same stub area.

Note the following points when configuring a stub area:

- The backbone area cannot be configured as a stub area.
- If an area needs to be configured as a stub area, all the devices in the area must be configured as stub devices using the **stub** command.
- An ASBR cannot exist in a stub area. Therefore, AS external routes cannot be advertised within the stub area.

## NSSA

Stub areas cannot import or transmit external routes, which prevents a large number of external routes from consuming the bandwidth and storage resources of routers in the stub areas. If you need to import external routes to an area and prevent these routes from consuming resources, configure the area as a not-so-stubby area (NSSA).

As a new type of area in OSPFv3, NSSAs resemble stub areas in many ways. Different from stub areas, NSSAs can import AS external routes and advertise them within the entire OSPFv3 AS, without learning external routes from other areas.

To advertise external routes imported by an NSSA to other areas on the OSPFv3 network, a translator must translate Type 7 LSAs into Type 5 LSAs.

### NOTE

- The propagate bit (P-bit) is used to notify a translator whether Type 7 LSAs need to be translated.
- By default, the translator is the ABR with the largest router ID in the NSSA.
- The P-bit is not set for Type 7 LSAs generated by an ABR.

## OSPFv3 Route Summarization

Routes with the same IPv6 prefix can be summarized into one route. On a large-scale OSPFv3 network, route lookup may slow down because of the large size of the routing table. To reduce the routing table size and simplify management, configure route summarization. With route summarization, if a link connected to a device within an IPv6 address range that has been summarized alternates between Up and Down, the link status change is not advertised to the devices beyond the IPv6 address range. This prevents route flapping and improves network stability.

OSPFv3 route summarization is classified as follows:

- Route summarization on an ABR

An ABR can summarize routes with the same prefix into one route and advertise the summarized route to other areas.

When an ABR transmits routing information to other areas, it generates Type 3 LSAs based on IPv6 address prefixes. If contiguous IPv6 address prefixes exist in this area and summarization is enabled on the ABR, these IPv6 address prefixes are summarized into one address prefix so that the ABR sends only one summary LSA. The LSAs of the specified network segments are not advertised.

- Route summarization on an ASBR

An ASBR can summarize imported routes with the same prefix into one route and then advertise the summarized route to other areas.

With route summarization, an ASBR summarizes imported Type 5 LSAs within the summarized address range. After route summarization, the ASBR does not generate a separate Type 5 LSA for each specific prefix within the configured range. Instead, the ASBR generates a Type 5 LSA for only the summarized prefix. In an NSSA, an ASBR summarizes multiple imported Type 7 LSAs within the summary address range into one Type 7 LSA.

## OSPFv3 Multi-process

OSPFv3 supports multi-process. Multiple OSPFv3 processes can independently run on the same router. Route exchange between different OSPFv3 processes is similar to that between different routing protocols.

## OSPFv3 and OSPFv2 Comparison

### Similarities:

- Network types and interface types
- Interface and neighbor state machines
- LSDB
- Flooding mechanism
- Five types of packets: Hello, DD, LSR, LSU, and LSAck packets
- Route calculation

### Differences:

- In OSPFv3, only LSAs in LSU packets contain address information.
- OSPFv3 is based on links rather than network segments.  
OSPFv3 runs over IPv6, which is based on links instead of network segments. As such, the interfaces on which OSPFv3 is to be configured must be on the same link, rather than on the same network segment. In addition, the interfaces can establish OSPFv3 connections without IPv6 global addresses.
- OSPFv3 does not depend on IP addresses.  
OSPFv3 separates topology calculation from IP addresses. OSPFv3 can calculate the OSPFv3 topology without knowing IPv6 global addresses, which are used only for virtual link interfaces and packet forwarding.
- OSPFv3 packets and the LSA format change.
  - OSPFv3 packets do not contain IP addresses.
  - OSPFv3 router-LSAs and network-LSAs do not contain IP addresses, which are advertised by link-LSAs and intra-area-prefix-LSAs.

- In OSPFv3, router IDs, area IDs, and LSA link state IDs no longer indicate IP addresses, but the IPv4 address format is still reserved.
  - Neighbors are identified by router IDs instead of IP addresses on broadcast, NBMA, or P2MP networks.
- Information about the flooding scope is added to OSPFv3 LSAs.  
Information about the flooding scope is added to the LSA Type field of OSPFv3 LSAs. Therefore, OSPFv3 routers can process LSAs of unidentified types.
    - OSPFv3 can store or flood unidentified packets, whereas OSPF discards unidentified packets.
    - OSPFv3 can flood unknown LSAs with the U bit set to 1. The LSA flooding scope is specified by the OSPFv3 LSA itself.
- For example, DeviceA and DeviceB can identify LSAs of a certain type. They are connected through DeviceC, but DeviceC cannot identify LSAs of this type. In this manner, when DeviceA floods such LSAs, DeviceC floods them to DeviceB without identifying them. After receiving the LSAs, DeviceB processes them.
- If OSPF is run, the unidentified LSAs are discarded, unable to reach DeviceB.
- OSPFv3 supports multi-process on a link.  
In OSPFv2, one physical interface can be bound to only one multi-instance. In OSPFv3, one physical interface can be bound to multiple instances, which are identified by different instance IDs. Each of these OSPFv3 instances can establish a neighbor relationship with the remote end of the same physical link and transmit packets. These instances do not interfere with each other. As such, link resources can be fully shared among these instances.
  - OSPFv3 uses IPv6 link-local addresses.  
IPv6 implements neighbor discovery, automatic configuration, and other functions based on link-local addresses. Devices running IPv6 do not forward IPv6 packets whose destination address is a link-local address. Those packets can only be exchanged on the same link. The unicast link-local address starts from FE80/10.  
As a routing protocol running over IPv6, OSPFv3 uses link-local addresses to maintain neighbor relationships and synchronize LSA databases. All OSPFv3 interfaces, except virtual link interfaces, use link-local addresses as the source address and the next hop address to transmit OSPFv3 packets.
- The advantages are as follows:
- OSPFv3 can calculate topologies without global IPv6 addresses, separating topologies from addresses.
  - The packets flooded on a link are not transmitted to other links. This minimizes unnecessary flooding and thereby saves bandwidth resources.
- OSPFv3 supports two new LSAs.
    - Link LSA: A device floods a link LSA on the link where it resides to advertise its link-local address and the configured global IPv6 address.
    - Intra-area prefix LSA: A device advertises an intra-area prefix LSA in the local area to inform the other devices in the area or the network (either a broadcast network or an NBMA network) of its IPv6 global address.

OSPFv3 identifies neighbors based on router IDs only.

On broadcast, NBMA, and P2MP networks, OSPF identifies neighbors based on the IPv4 addresses of interfaces.

## OSPFv3 Packet Format

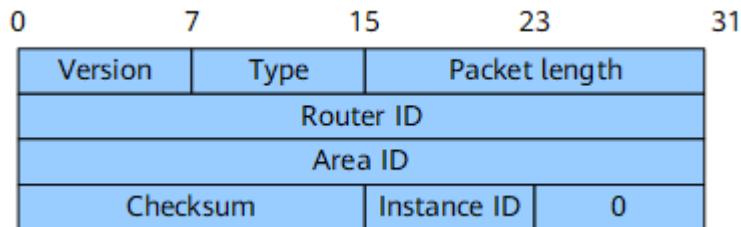

Open Shortest Path First (OSPF) for IPv6 packets are encapsulated into IPv6 packets. The OSPFv3 protocol number is 89. OSPFv3 packets are classified into the following types:

- **Hello packet**
- **Database Description (DD) packet**
- **Link State Request (LSR) packet**
- **Link State Update (LSU) packet**
- **Link State Acknowledgment (LSAck) packet**

## Packet Header Format

The five types of OSPFv3 packets have the same packet header format. The length of an OSPFv3 packet header is 16 bytes. [Figure 1-142](#) shows an OSPFv3 packet header.

**Figure 1-142** OSPFv3 packet header

**Table 1-57** Packet header fields

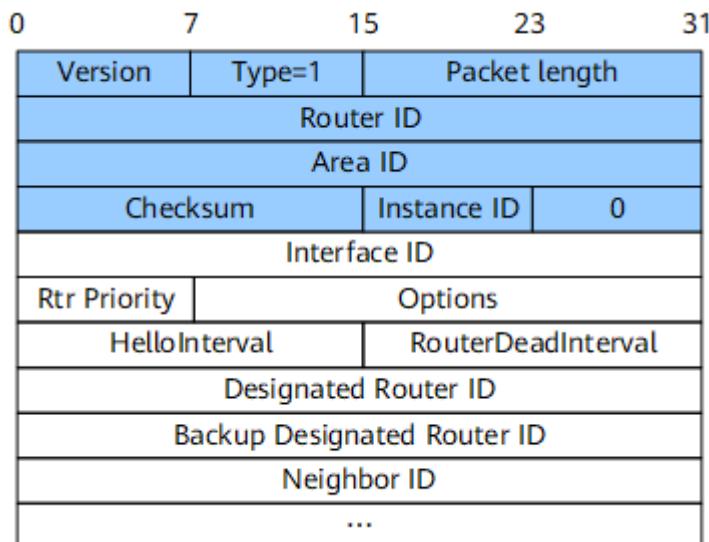

| Field         | Length  | Description                                                                                                                                                                                                       |
|---------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Version       | 8 bits  | OSPF version number. For OSPFv3, the value is 3.                                                                                                                                                                  |
| Type          | 8 bits  | OSPFv3 packet type. The values are as follows: <ul style="list-style-type: none"><li>• 1: Hello packet</li><li>• 2: DD packet</li><li>• 3: LSR packet</li><li>• 4: LSU packet</li><li>• 5: LSAck packet</li></ul> |
| Packet length | 16 bits | Length of the OSPFv3 packet containing the packet header, in bytes.                                                                                                                                               |
| Router ID     | 32 bits | ID of the router that sends the OSPFv3 packet.                                                                                                                                                                    |
| Area ID       | 32 bits | ID of the area to which the router that sends the OSPFv3 packet belongs.                                                                                                                                          |

| Field       | Length  | Description                                                                   |
|-------------|---------|-------------------------------------------------------------------------------|
| Checksum    | 16 bits | Checksum of the OSPFv3 packet that does not contain the Authentication field. |
| Instance ID | 8 bits  | ID of an OSPFv3 instance.                                                     |
| 0           | 8 bits  | Reserved fields.                                                              |

## Hello Packet

Hello packets are commonly used packets, which are periodically sent on OSPFv3 interfaces to establish and maintain neighbor relationships. A Hello packet includes information about the designated router (DR), backup designated router (BDR), timers, and known neighbors. **Figure 1-143** shows the format of a Hello packet.

**Figure 1-143** Format of a Hello packet

**Table 1-58** Hello packet fields

| Field        | Length  | Description                                                                                                                                                            |
|--------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface ID | 32 bits | ID of the interface that sends the Hello packets.                                                                                                                      |
| Rtr Priority | 8 bits  | DR priority. The default value is 1.<br><b>NOTE</b><br>If the DR priority of a router interface is set to 0, the interface cannot participate in a DR or BDR election. |

| Field                       | Length  | Description                                                                                                                                                                                                                                                                   |
|-----------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Options                     | 24 bits | The values are as follows: <ul style="list-style-type: none"><li>• E: Type 5 link state advertisements (LSAs) are flooded.</li><li>• MC: IP multicast packets are forwarded.</li><li>• N/P: Type 7 LSAs are processed.</li><li>• DC: On-demand links are processed.</li></ul> |
| HelloInterval               | 16 bits | Interval at which Hello packets are sent.                                                                                                                                                                                                                                     |
| RouterDeadInterval          | 16 bits | Dead interval. If a router does not receive any Hello packets from its neighbors within a specified dead interval, the neighbors are considered Down.                                                                                                                         |
| Designated Router ID        | 32 bits | Router ID of the DR.                                                                                                                                                                                                                                                          |
| Backup Designated Router ID | 32 bits | Router ID of the BDR.                                                                                                                                                                                                                                                         |
| Neighbor ID                 | 32 bits | Router ID of the neighbor.                                                                                                                                                                                                                                                    |

**Table 1-59** lists the address types, interval types, and default intervals used when Hello packets are transmitted on different networks.

**Table 1-59** Hello packet characteristics for various network types

| Network Type                         | Address Type      | Interval Type                                                                                                                                                                                                     | Default Interval                                             |
|--------------------------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| Broadcast                            | Multicast address | HelloInterval                                                                                                                                                                                                     | 10 seconds                                                   |
| Non-broadcast multiple access (NBMA) | Unicast address   | <ul style="list-style-type: none"><li>• HelloInterval for the DR, BDR, and router that can become a DR</li><li>• PollInterval for the case when neighbors become Down and HelloInterval for other cases</li></ul> | 30 seconds for HelloInterval<br>120 seconds for PollInterval |
| Point-to-point (P2P)                 | Multicast address | HelloInterval                                                                                                                                                                                                     | 10 seconds                                                   |

| Network Type               | Address Type      | Interval Type | Default Interval |
|----------------------------|-------------------|---------------|------------------|
| Point-to-multipoint (P2MP) | Multicast address | HelloInterval | 30 seconds       |

#### NOTE

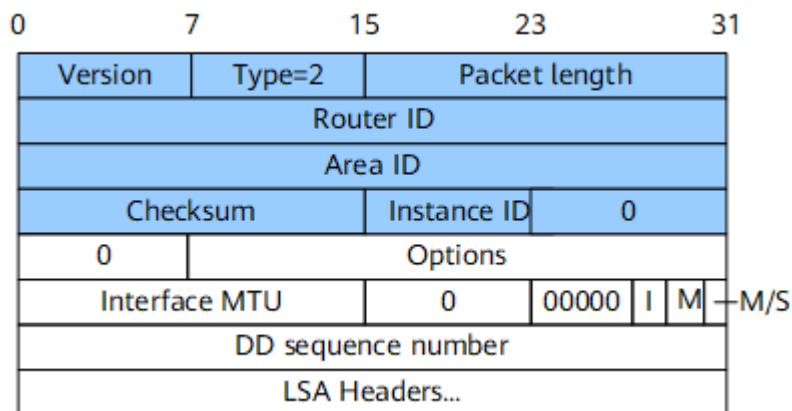

To establish neighbor relationships between routers on the same network segment, you must set the same HelloInterval, PollInterval, and RouterDeadInterval values for the routers. PollInterval applies only to NBMA networks.

## DD Packet

During an adjacency initialization, two routers use DD packets to describe their own link state databases (LSDBs) for LSDB synchronization. A DD packet contains the header of each LSA in an LSDB. An LSA header uniquely identifies an LSA. The LSA header occupies only a small portion of the LSA, which reduces the amount of traffic transmitted between routers. A neighbor can use the LSA header to check whether it already has the LSA. When two routers exchange DD packets, one functions as the master and the other functions as the slave. The master defines a start sequence number. The master increases the sequence number by one each time it sends a DD packet. After the slave receives a DD packet, it uses the sequence number carried in the DD packet for acknowledgment.

[Figure 1-144](#) shows the format of a DD packet.

[Figure 1-144](#) Format of a DD packet

**Table 1-60** DD packet fields

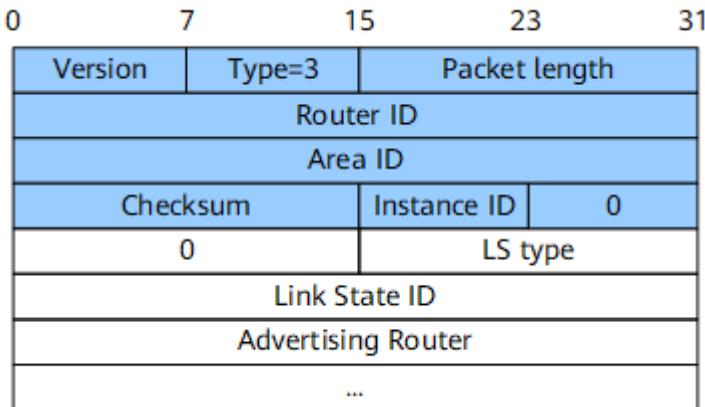

| Field              | Length  | Description                                                                                                                                                                                                                                       |
|--------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Options            | 24 bits | The values are as follows: <ul style="list-style-type: none"><li>● E: Type 5 LSAs are flooded.</li><li>● MC: IP multicast packets are forwarded.</li><li>● N/P: Type 7 LSAs are processed.</li><li>● DC: On-demand links are processed.</li></ul> |
| Interface MTU      | 16 bits | Maximum length of the DD packet sent by the interface with packet fragmentation disabled.                                                                                                                                                         |
| I                  | 1 bit   | If the DD packet is the first packet among multiple consecutive DD packets sent by a router, this field is set to 1. In other cases, this field is set to 0.                                                                                      |
| M (More)           | 1 bit   | If the DD packet is the last packet among multiple consecutive DD packets sent by a router, this field is set to 0. In other cases, this field is set to 1.                                                                                       |
| M/S (Master/Slave) | 1 bit   | When two routers exchange DD packets, they negotiate a master/slave relationship. The router with a larger router ID becomes the master. If this field is set to 1, the DD packet is sent by the master.                                          |
| DD sequence number | 32 bits | Sequence number of the DD packet. The master and slave use the sequence number to ensure that DD packets are correctly transmitted.                                                                                                               |
| LSA Headers        | -       | LSA header information included in the DD packet.                                                                                                                                                                                                 |

## LSR Packet

After two routers exchange DD packets, they send LSR packets to request each other's LSAs. The LSR packets contain the summaries of the requested LSAs.

[Figure 1-145](#) shows the format of an LSR packet.

[Figure 1-145](#) Format of an LSR packet

**Table 1-61** LSR packet fields

| Field              | Length  | Description                                                           |
|--------------------|---------|-----------------------------------------------------------------------|
| LS type            | 16 bits | Type of the LSA                                                       |
| Link State ID      | 32 bits | This field together with the LS type field describes an LSA in an AS. |
| Advertising Router | 32 bits | Router ID of the router that generates the LSA.                       |

 **NOTE**

The LS type, Link State ID, and Advertising Router fields can uniquely identify an LSA. If two LSAs have the same LS type, Link State ID, and Advertising Router fields, a router uses the LS sequence number, LS checksum, and LS age fields to obtain a required LSA.

## LSU Packet

A router uses an LSU packet to transmit LSAs requested by its neighbors or to flood its own updated LSAs. The LSU packet contains a set of LSAs. For multicast and broadcast networks, LSU packets are multicast to flood LSAs. To ensure reliable LSA flooding, a router uses an LSAck packet to acknowledge the LSAs contained in an LSU packet that is received from a neighbor. If an LSA fails to be acknowledged, the router retransmits the LSA to the neighbor. [Figure 1-146](#) shows the format of an LSU packet.

[Figure 1-146](#) Format of an LSU packet

**Table 1-62** LSU packet field

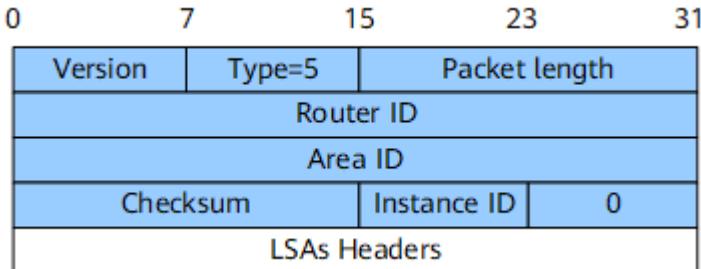

| Field          | Length  | Description                                |
|----------------|---------|--------------------------------------------|
| Number of LSAs | 32 bits | Number of LSAs contained in the LSU packet |

## LSAck Packet

A router uses an LSAck packet to acknowledge the LSAs contained in a received LSU packet. The LSAs can be acknowledged using LSA headers. LSAck packets can

be transmitted over different links in unicast or multicast mode. [Figure 1-147](#) shows the format of an LSAck packet.

**Figure 1-147** Format of an LSAck packet

**Table 1-63** LSAck packet field

| Field        | Length                                                         | Description                               |
|--------------|----------------------------------------------------------------|-------------------------------------------|
| LSAs Headers | Determined by the header length of the LSA to be acknowledged. | This field is used to acknowledge an LSA. |

## OSPFv3 LSA Format

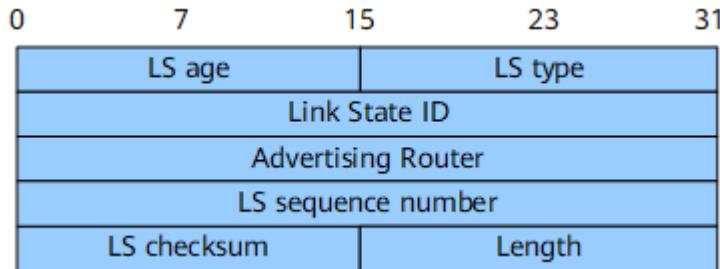

Each router in an autonomous system (AS) generates one or more types of link state advertisements (LSAs), depending on the router's type. Multiple LSAs form a link state database (LSDB). OSPFv3 encapsulates routing information into LSAs for transmission. Commonly used LSAs include:

- [Router-LSA \(Type 1\)](#)
- [Network-LSA \(Type 2\)](#)
- [Inter-Area-Prefix-LSA \(Type 3\)](#)
- [Inter-Area-Router-LSA \(Type 4\)](#)
- [AS-external-LSA \(Type 5\)](#)
- [NSSA LSA \(Type 7\)](#)
- [Link-LSA \(Type 8\)](#)
- [Intra-Area-Prefix-LSA \(Type 9\)](#)

## LSA Header Format

All LSAs have the same header. [Figure 1-148](#) shows an LSA header.

**Figure 1-148 LSA header**

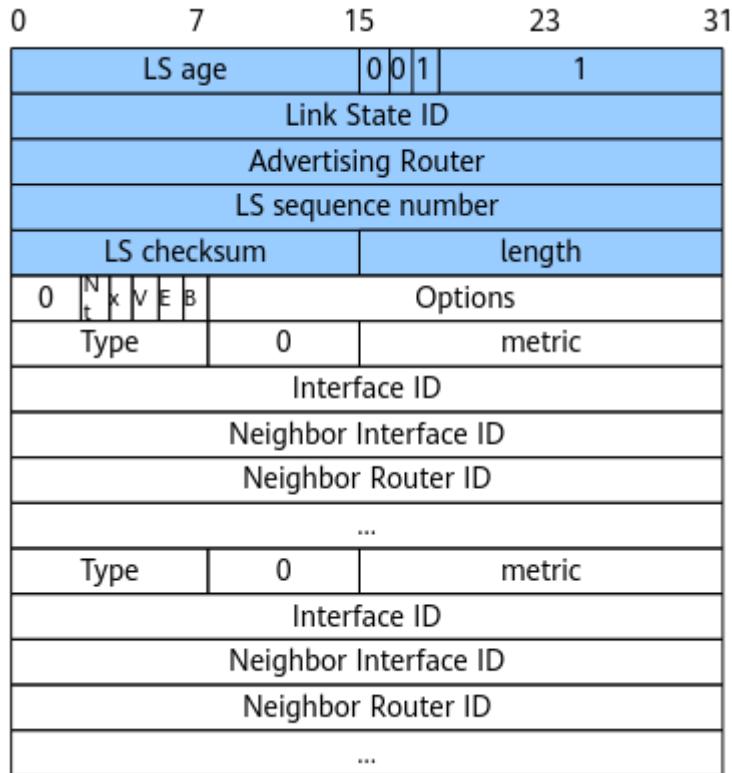

**Table 1-64 LSA header fields**

| Field              | Length  | Description                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LS age             | 16 bits | Time that elapses after the LSA is generated, in seconds. The value of this field continually increases regardless of whether the LSA is transmitted over a link or saved in an LSDB.                                                                                                                                                                                           |
| LS type            | 16 bits | Type of the LSA. The values are as follows: <ul style="list-style-type: none"> <li>• Type 1: Router-LSA.</li> <li>• Type 2: Network-LSA.</li> <li>• Type 3: Inter-Area-Prefix-LSA.</li> <li>• Type 4: Inter-Area-Router-LSA.</li> <li>• Type 5: AS-external-LSA.</li> <li>• Type 7: NSSA-LSA.</li> <li>• Type 8: Link-LSA.</li> <li>• Type 9: Intra-Area-Prefix-LSA.</li> </ul> |
| Link State ID      | 32 bits | This field together with the LS type field describes an LSA in an area.                                                                                                                                                                                                                                                                                                         |
| Advertising Router | 32 bits | Router ID of the router that generates the LSA.                                                                                                                                                                                                                                                                                                                                 |
| LS sequence number | 32 bits | Sequence number of the LSA. Routers can use this field to identify the latest LSA.                                                                                                                                                                                                                                                                                              |
| LS checksum        | 16 bits | Checksum of all fields except the LS age field.                                                                                                                                                                                                                                                                                                                                 |
| Length             | 16 bits | Length of the LSA including the LSA header, in bytes.                                                                                                                                                                                                                                                                                                                           |

## Router-LSA

A router-LSA (Type 1) describes the link status and cost of a router. Router-LSAs are generated by a router and advertised within the area to which the router belongs. [Figure 1-149](#) shows the format of a router-LSA.

**Figure 1-149** Format of a router-LSA

**Table 1-65** Router-LSA fields

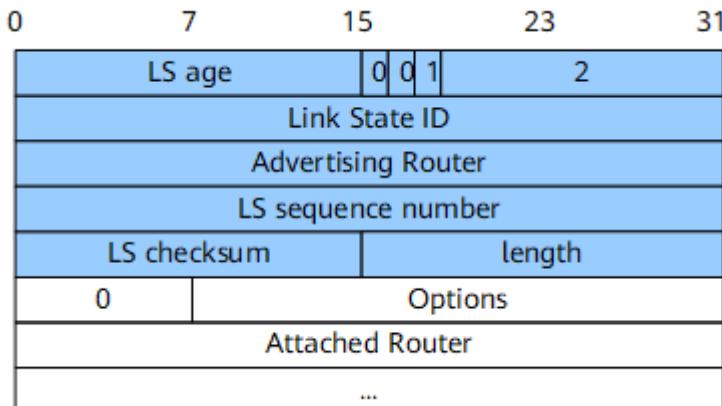

| Field                 | Length  | Description                                                                                                                                                                                                                        |
|-----------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Nt (NSSA translation) | 1 bit   | If the router that generates the LSA is an NSSA border router, this field is set to 1. In other cases, this field is set to 0. When this field is set to 1, the router unconditionally translates NSSA-LSAs into AS-external-LSAs. |
| x                     | 1 bit   | This field is deprecated.                                                                                                                                                                                                          |
| V (Virtual Link)      | 1 bit   | If the router that generates the LSA is located at one end of a virtual link, this field is set to 1. In other cases, this field is set to 0.                                                                                      |
| E (External)          | 1 bit   | If the router that generates the LSA is an autonomous system boundary router (ASBR), this field is set to 1. In other cases, this field is set to 0.                                                                               |
| B (Border)            | 1 bit   | If the router that generates the LSA is an area border router (ABR), this field is set to 1. In other cases, this field is set to 0.                                                                                               |
| Options               | 24 bits | The optional capabilities supported by the router.                                                                                                                                                                                 |

| Field                 | Length  | Description                                                                                                                                                                                                                                                              |
|-----------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type                  | 8 bits  | Type of the router link. The values are as follows: <ul style="list-style-type: none"> <li>• 1: Connected to another router in point-to-point (P2P) mode.</li> <li>• 2: Connected to a transport network.</li> <li>• 3: Reserved.</li> <li>• 4: Virtual link.</li> </ul> |
| metric                | 16 bits | Cost of the link.                                                                                                                                                                                                                                                        |
| Interface ID          | 32 bits | The Interface ID assigned to the interface.                                                                                                                                                                                                                              |
| Neighbor Interface ID | 32 bits | Neighbor's interface ID. <ul style="list-style-type: none"> <li>• For transit links, the value is the interface ID of the DR.</li> <li>• For links of other types, the value is the interface ID of the neighboring device.</li> </ul>                                   |
| Neighbor Router ID    | 32 bits | Router ID of the neighbor. <ul style="list-style-type: none"> <li>• For transit links, the value is the router ID of the DR.</li> <li>• For links of other types, the value is the router ID of the neighboring device.</li> </ul>                                       |

## Network-LSA

A network-LSA (Type 2) records the router IDs of all routers on the local network segment. Network-LSAs are generated by a DR on a broadcast or non-broadcast multiple access (NBMA) network and advertised within the area to which the DR belongs. [Figure 1-150](#) shows the format of a network-LSA.

**Figure 1-150** Format of a network-LSA

**Table 1-66** Network-LSA fields

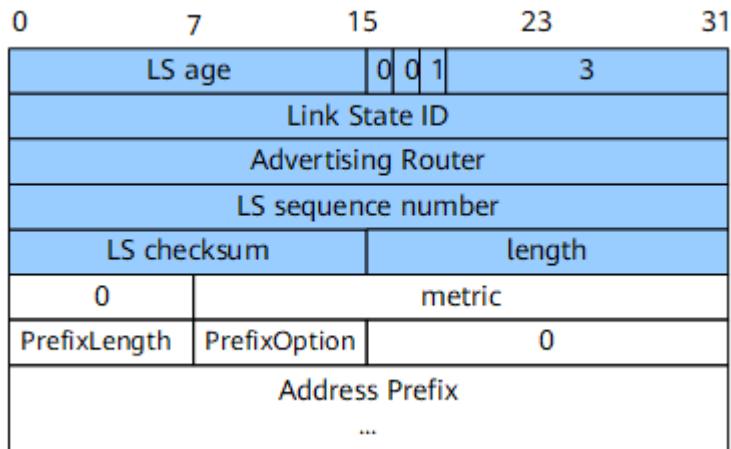

| Field           | Length  | Description                                                                      |
|-----------------|---------|----------------------------------------------------------------------------------|
| Options         | 24 bits | The optional capabilities supported by the router.                               |
| Attached Router | 32 bits | Router IDs of all routers on the same network, including the router ID of the DR |

## Inter-Area-Prefix-LSA

An inter-area-prefix-LSA (Type 3) describes routes on a network segment in an area. It is generated by the ABR. The routes are advertised to other areas.

[Figure 1-151](#) shows the format of an inter-area-prefix-LSA.

**Figure 1-151** Format of an inter-area-prefix-LSA

**Table 1-67** Inter-area-prefix-LSA fields

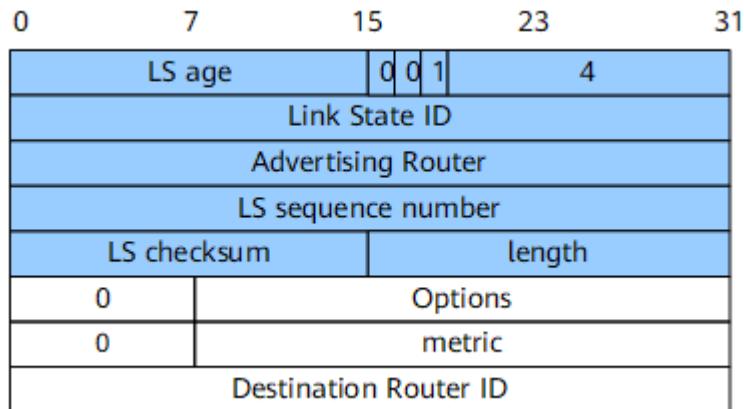

| Field          | Length  | Description                                                            |
|----------------|---------|------------------------------------------------------------------------|
| PrefixLength   | 8 bits  | Length of the prefix.                                                  |
| PrefixOption   | 8 bits  | Prefix-related capability option, indicating the length in the packet. |
| Address Prefix | 32 bits | Address prefix.                                                        |

## Inter-Area-Router-LSA

An inter-area-router-LSA (Type 4) describes routes to the ASBR in other areas. It is generated by the ABR. The routes are advertised to all related areas except the area that the ASBR belongs to.

[Figure 1-152](#) shows the format of an inter-area-router-LSA.

**Figure 1-152** Format of an inter-area-router-LSA

**Table 1-68** Inter-area-router-LSA fields

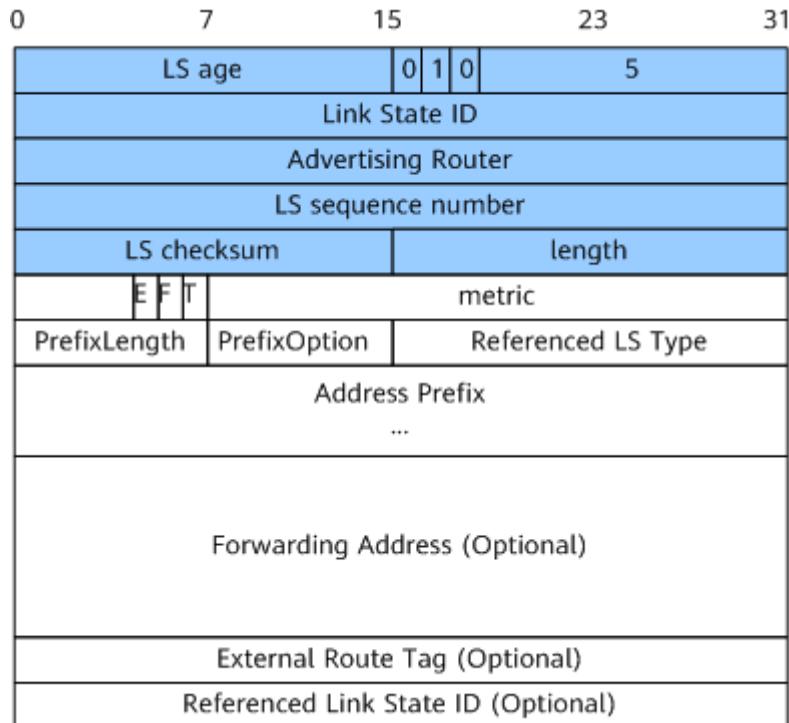

| Field                 | Length  | Description                                       |
|-----------------------|---------|---------------------------------------------------|
| Destination Router ID | 32 bits | The router ID of the router described by the LSA. |

## AS-External-LSA

An AS-external-LSA describes a route to a destination outside the AS and is generated by an ASBR.

**Figure 1-153** shows the format of an AS-external-LSA.

**Figure 1-153** Format of an AS-external-LSA

**Table 1-69 AS-external-LSA fields**

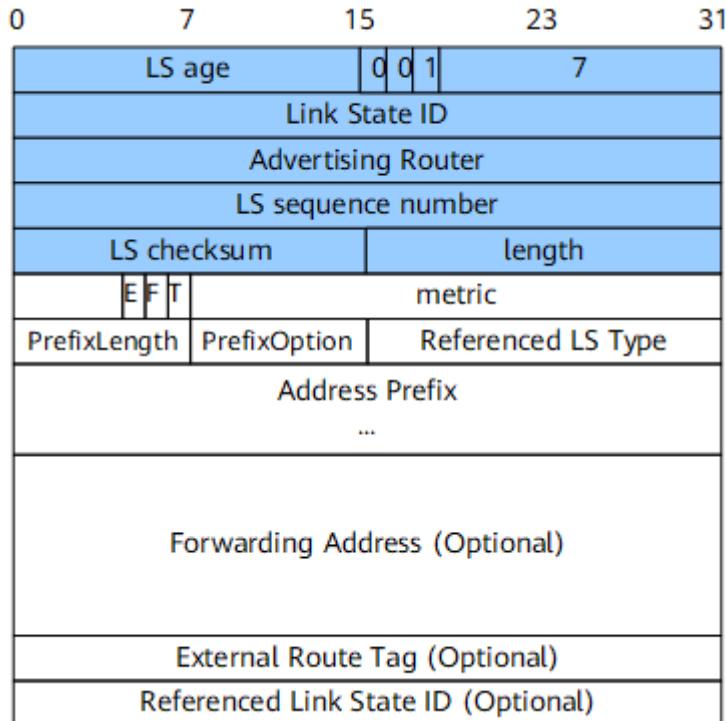

| Field                    | Length   | Description                                                                                                                                                                                                                                                       |
|--------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E                        | 1 bit    | Type of external metric. <ul style="list-style-type: none"><li>● If this field is 1, the specified metric is a Type 2 external metric.</li><li>● If this field is 0, the specified metric is a Type 1 external metric.</li></ul>                                  |
| F                        | 1 bit    | Whether a Forwarding Address has been included in the LSA. <ul style="list-style-type: none"><li>● If this field is 1, a Forwarding Address has been included in the LSA.</li><li>● If this field is 0, no Forwarding Address is included in the LSA.</li></ul>   |
| T                        | 1 bit    | Whether an External Route Tag has been included in the LSA. <ul style="list-style-type: none"><li>● If this field is 1, an External Route Tag has been included in the LSA.</li><li>● If this field is 0, no External Route Tag is included in the LSA.</li></ul> |
| Referenced LS Type       | 16 bits  | Referenced LS type. If this value is not 0, an LSA with this LS type is to be associated with this LSA (see Referenced Link State ID below).                                                                                                                      |
| Forwarding Address       | 128 bits | A fully qualified global IPv6 address.                                                                                                                                                                                                                            |
| External Route Tag       | 32 bits  | External route tag, which can be used to communicate additional information between ASBRs.                                                                                                                                                                        |
| Referenced Link State ID | 32 bits  | Referenced link state ID.                                                                                                                                                                                                                                         |

## NSSA-LSA

NSSA-LSAs are originated by ASBRs within an NSSA and describe routes to destinations external to the AS.

[Figure 1-154](#) shows the format of an NSSA-LSA.

**Figure 1-154** Format of an NSSA-LSA

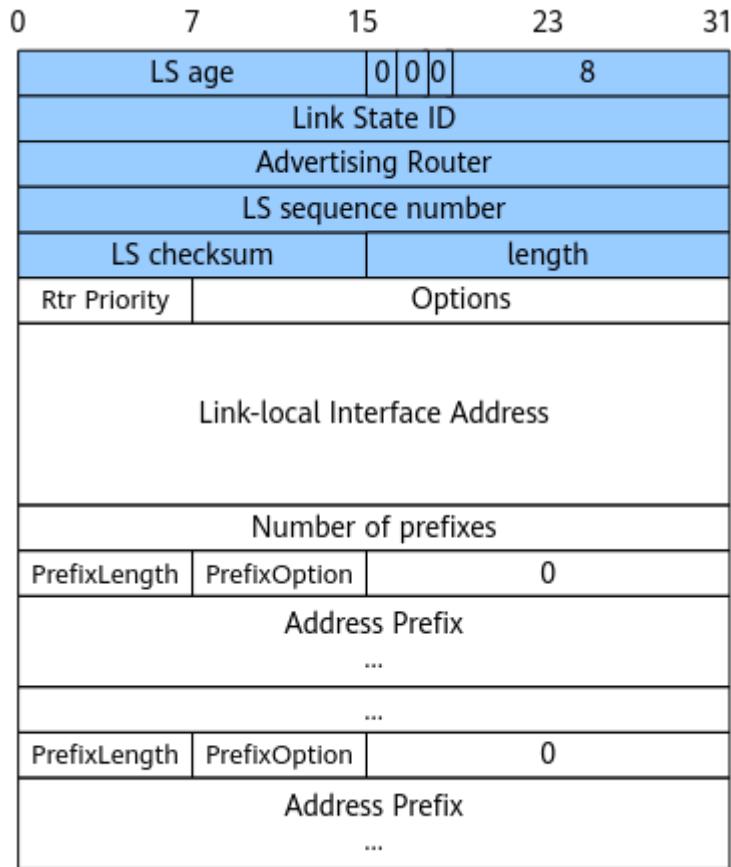

## Link-LSA

Each router generates a link LSA for each link. A link LSA describes the link-local address and IPv6 address prefix associated with the link and the link option set in the network LSA. It is transmitted only on the link.

[Figure 1-155](#) shows the format of a link-LSA.

**Figure 1-155** Format of a Link-LSA

**Table 1-70** Link-LSA fields

| Field                        | Length   | Description                                                                                       |
|------------------------------|----------|---------------------------------------------------------------------------------------------------|
| Rtr Priority                 | 8 bits   | Router priority of the interface.                                                                 |
| Options                      | 24 bits  | Set of options that may be set in the network-LSA generated by the DR on broadcast or NBMA links. |
| Link-local Interface Address | 128 bits | The originating router's link-local interface address on the link.                                |
| Number of prefixes           | 32 bits  | Number of IPv6 address prefixes contained in the LSA.                                             |

## Intra-Area-Prefix-LSA

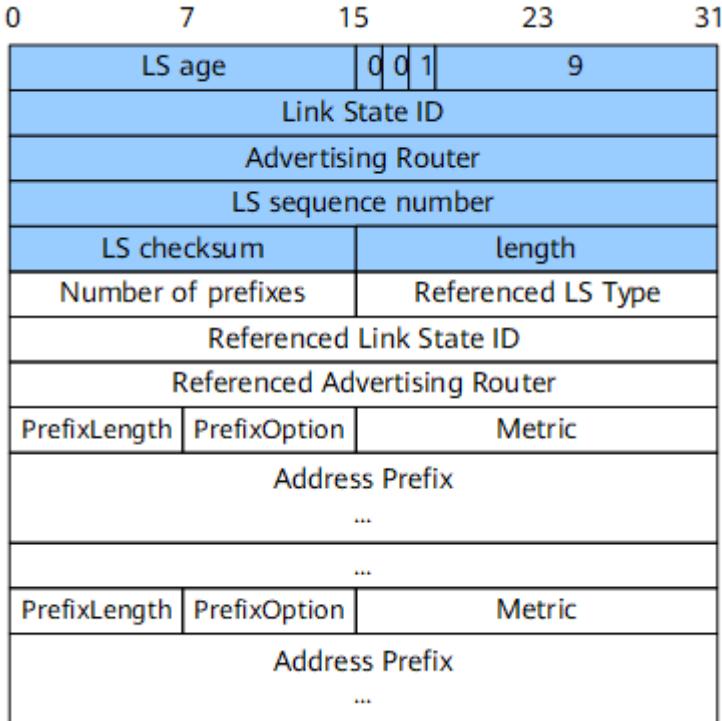

Each router and DR generates one or such LSAs and transmits them in the local area.

- An LSA generated on a router describes the IPv6 address prefix associated with the router LSA.

- Such LSAs generated by a DR describe the IPv6 address prefixes associated with network LSAs.

[Figure 1-156](#) shows the format of an intra-area-prefix-LSA.

**Figure 1-156** Format of an intra-area-prefix-LSA

**Table 1-71** Intra-area-prefix-LSA fields

| Field                    | Length  | Description                                                                                                                                                                                                                                                                                                                       |
|--------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Referenced LS Type       | 16 bits | <p>Router-LSA or network-LSA with which the IPv6 address prefixes should be associated.</p> <ul style="list-style-type: none"> <li>If Referenced LS Type is 0x2001, the IPv6 prefixes are associated with a router-LSA.</li> <li>If Referenced LS Type is 0x2002, the IPv6 prefixes are associated with a network-LSA.</li> </ul> |
| Referenced Link State ID | 32 bits | <p>Referenced link state ID.</p> <ul style="list-style-type: none"> <li>If Referenced LS Type is 0x2001, Referenced Link State ID should be 0.</li> <li>If Referenced LS Type is 0x2002, Referenced Link State ID should be the interface ID of the link's DR.</li> </ul>                                                         |

| Field                         | Length  | Description                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Referenced Advertising Router | 32 bits | <p>ID of the referenced advertising router.</p> <ul style="list-style-type: none"><li>• If Referenced LS Type is 0x2001, Referenced Advertising Router should be the originating router's router ID.</li><li>• If Referenced LS Type is 0x2002, Referenced Advertising Router should be the DR's router ID.</li></ul> |

## BFD for OSPFv3

### Definition

Bidirectional Forwarding Detection (BFD) is a mechanism to detect communication faults between forwarding engines.

To be specific, BFD detects the connectivity of a data protocol along a path between two systems. The path can be a physical link, a logical link, or a tunnel.

In BFD for OSPFv3, a BFD session is associated with OSPFv3. The BFD session quickly detects a link fault and then notifies OSPFv3 of the fault, which speeds up OSPFv3's response to network topology changes.

### Purpose

A link fault or a topology change causes devices to recalculate routes. Therefore, it is important to shorten the convergence time of routing protocols to improve network performance.

As link faults are inevitable, rapidly detecting these faults and notifying routing protocols is an effective way to quickly resolve such issues. If BFD is associated with the routing protocol and a link fault occurs, BFD can speed up the convergence of the routing protocol.

**Table 1-72** BFD for OSPFv3

| With or Without BFD | Link Fault Detection Mechanism | Convergence Speed |
|---------------------|--------------------------------|-------------------|
| Without BFD         | The OSPFv3 Dead timer expires. | Second-level      |
| With BFD            | A BFD session goes Down.       | Millisecond-level |

## Principles

Figure 1-157 BFD for OSPFv3

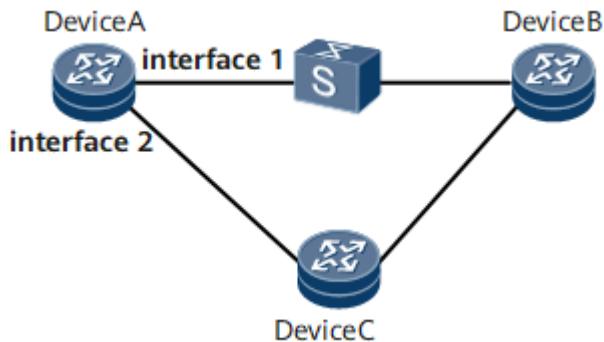

Figure 1-157 shows a typical network topology with BFD for OSPFv3 configured. The principles of BFD for OSPFv3 are described as follows:

1. OSPFv3 neighbor relationships are established between the three devices.
2. After a neighbor relationship becomes Full, a BFD session is established.
3. The outbound interface of the route from DeviceA to DeviceB is interface 1. If the link between DeviceA and DeviceB fails, BFD detects the fault and notifies DeviceA of the fault.
4. DeviceA processes the neighbor Down event and recalculates the route. The new outbound interface of the route is interface 2. Packets from DeviceA pass through DeviceC to reach DeviceB.

## Priority-based Convergence

Priority-based OSPFv3 convergence ensures that some routes converge first if a great number of routes are available. Different routes can be set with different convergence priorities. This allows important routes to converge first and therefore improves network reliability.

With priority-based OSPFv3 convergence, you can set a higher priority for the routes related to key services so that these routes converge first and the impact on key services is minimized.

## OSPFv3 IP FRR

OSPFv3 IP fast reroute (FRR) is dynamic IP FRR, and refers to the process by which OSPFv3 precomputes a backup path based on the network-wide LSDBs, and stores this backup path in the forwarding table. If the primary path fails, traffic can be protected and the fault recovery time is shortened.

OSPFv3 IP FRR complies with standard protocols and provides link and node protection for traffic.

## Background

As networks develop, Voice over Internet Protocol (VoIP) and online video services pose higher requirements for real-time transmission. Nevertheless, if a primary link fails, OSPFv3-enabled devices need to perform multiple operations, including

detecting the fault, updating the LSA, flooding the LSA, calculating routes, and delivering forward information base (FIB) entries before switching traffic to a new link. This process takes a much longer time than the minimum delay to which users are sensitive. As a result, the requirements for real-time transmission cannot be met.

## Fundamentals

OSPFv3 IP FRR refers to a mechanism in which a device uses the loop-free alternate (LFA) algorithm to precompute a backup link, and stores the primary and backup links to the forwarding table. If the primary link fails, OSPFv3 IP FRR switches traffic to the backup link before route convergence is complete on the control plane. This ensures uninterrupted traffic transmission and greatly improves OSPFv3 network reliability. The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports OSPFv3 IP FRR.

A device uses the shortest path first (SPF) algorithm to calculate the shortest path from each neighbor that can provide a backup link to the destination node. The device then uses an inequality defined in the standard protocol to calculate the loop-free backup link with the lowest cost among available shortest paths.

An OSPFv3 IP FRR policy is used to filter backup routes to be added to the IP routing table. Only the backup routes that match the filtering rules of the policy can be added to the IP routing table. Users can configure a desired OSPFv3 IP FRR to filter backup routes.

If a Bidirectional Forwarding Detection (BFD) session is bound to OSPFv3 IP FRR, the BFD session goes down if BFD detects a link fault. If the BFD session goes down, OSPFv3 IP FRR is triggered on the interface to switch traffic from the faulty link to the backup link, which minimizes the loss of traffic.

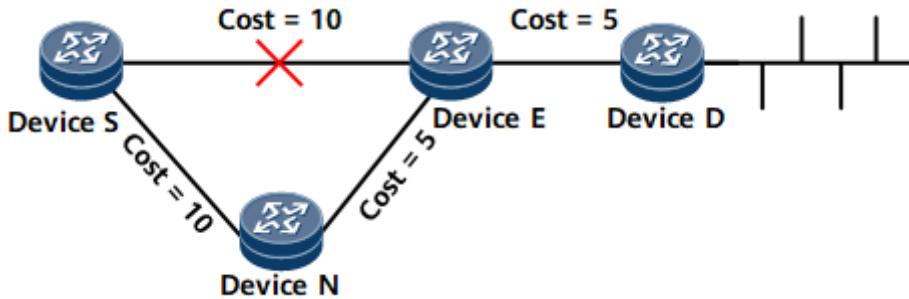

## Usage Scenario

OSPFv3 IP FRR guarantees protection against either a link failure or a node-and-link failure. Distance\_opt (X, Y) indicates the shortest path from node X to node Y.

- **Link protection:** Link protection takes effect when the traffic to be protected flows along a specified link and the link costs meet the inequality:  
$$\text{Distance}_{\text{opt}}(\text{N}, \text{D}) < \text{Distance}_{\text{opt}}(\text{N}, \text{S}) + \text{Distance}_{\text{opt}}(\text{S}, \text{D}).$$
  - S: source node
  - N: node along a backup link
  - D: destination node

On the network shown in [Figure 1-158](#), traffic is forwarded from DeviceS to DeviceD. The primary link is DeviceS -> DeviceE -> DeviceD, and the backup link is DeviceS -> DeviceN -> DeviceE -> DeviceD. The link costs satisfy the link protection inequality. If the primary link fails, DeviceS switches the traffic to the backup link and then traffic can be forwarded to downstream devices, minimizing the traffic interruption duration.

Figure 1-158 Networking for OSPFv3 IP FRR link protection

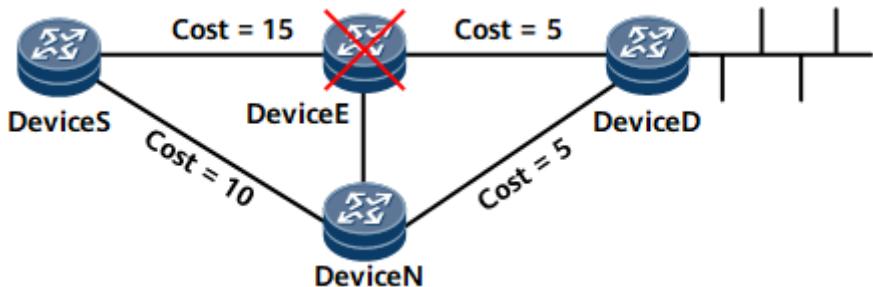

- **Link-and-node protection:** Node-and-link protection takes effect when the traffic to be protected flows along a specified link and node. [Figure 1-159](#) shows the networking for link-and-node protection. The link-and-node protection takes precedence over the link protection.

Link-and-node protection must satisfy the following conditions:

- The link cost must satisfy the inequality:  $\text{Distance}_{\text{opt}}(N, D) < \text{Distance}_{\text{opt}}(N, S) + \text{Distance}_{\text{opt}}(S, D)$ .
- The interface cost must satisfy the inequality:  $\text{Distance}_{\text{opt}}(N, D) < \text{Distance}_{\text{opt}}(N, E) + \text{Distance}_{\text{opt}}(E, D)$ .

S indicates the source node of traffic, E indicates the faulty node, N indicates the node on the backup link, and D indicates the destination node of traffic.

Figure 1-159 Networking for OSPFv3 IP FRR link-and-node protection

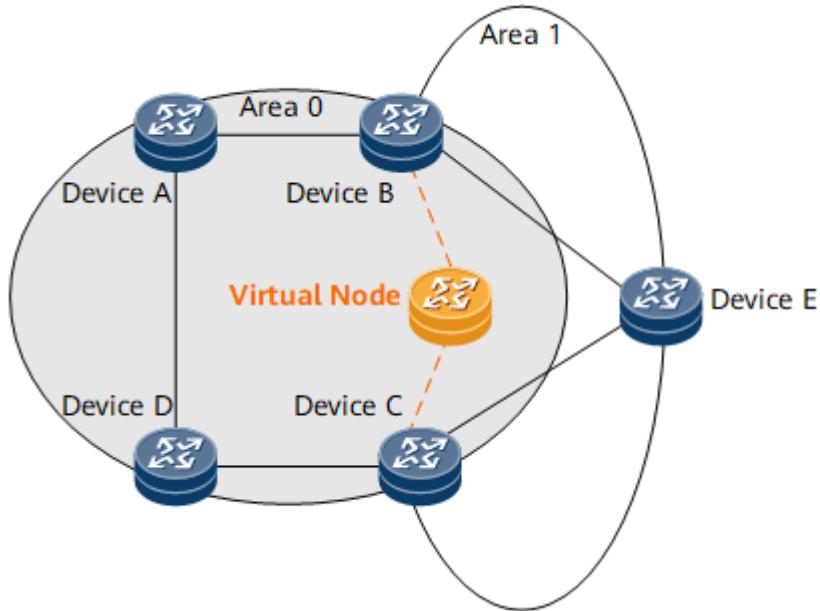

## OSPFv3 FRR in the Scenario Where Multiple Nodes Advertise the Same Route

OSPFv3 IP FRR uses the SPF algorithm to calculate the shortest path from each neighbor (root node) that provides a backup link to the destination node and store the node-based backup next hop, which applies to single-node routing scenarios. As networks are increasingly diversified, two ABRs or ASBRs are deployed to improve network reliability. In this case, OSPFv3 FRR in a scenario where multiple nodes advertise the same route is needed.

 NOTE

In a scenario where multiple nodes advertise the same route, OSPFv3 FRR is implemented by calculating the Type 3 LSAs advertised by ABRs of an area for intra-area, inter-area, and ASE routing. Inter-area routing is used as an example to describe how OSPFv3 FRR works in a scenario where multiple nodes advertise the same route.

**Figure 1-160** OSPFv3 FRR in the scenario where multiple nodes advertise the same route

In **Figure 1-160**, Device B and Device C function as ABRs to forward routes between area 0 and area 1. Device E advertises an intra-area route. Upon receipt of the route, Device B and Device C translate it into a Type 3 LSA and flood the LSA to area 0. After OSPFv3 FRR is enabled on Device A, Device A considers both Device B and Device C as its neighbors. Without a fixed neighbor as the root node, Device A fails to calculate the FRR backup next hop. To address this problem, a virtual node is simulated between Device B and Device C, which converts multi-node routing into single-node routing and uses the LFA algorithm to calculate the backup next hop of the virtual node. The same route advertised by multiple nodes inherits the backup next hop from the virtual node created by the node.

For example, both Device B and Device C advertise the route 2001:DB8:1::1/64, and OSPFv3 FRR is enabled on Device A. After Device A receives the route, it fails to calculate a backup next hop for the route due to a lack of a fixed root node. To address this problem, a virtual node is simulated between Device B and Device C. The virtual node forms a link with each of Device B and Device C. If the virtual node advertises a 2001:DB8:1::1/64 route, it will use the smaller cost of the routes advertised by Device B and Device C as the cost of the route. If the cost of the route advertised by Device B is 5 and that of the route advertised by Device C is 10, the cost of the route advertised by the virtual node is 5. The cost of the link from Device B to the virtual node is 0, and that of the link from Device C to the virtual node is 5. The costs of the links from the virtual node to Device B and Device C are both 65535, the maximum value. Device A is configured to consider Device B and Device C as invalid sources of the 2001:DB8:1::1/64 route and use the

LFA algorithm to calculate the backup next hop for the route, with the virtual node as the root node.

## OSPFv3 GR

### NOTE

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X can be configured as a GR helper rather than a GR restarter.

Graceful Restart (GR) ensures normal traffic forwarding without affecting key services during the restart of routing protocols.

Without GR, the active/standby switchover triggered by any reason leads to transient service interruption, and as a result, route flapping occurs on the whole network. For a large-scale network, the route flapping and service interruption are unacceptable.

GR is a high availability (HA) technology. HA technologies comprise a set of comprehensive techniques, such as fault-tolerant redundancy, link protection, faulty node recovery, and traffic engineering. GR is a fault-tolerant redundancy technology. It has been widely used in active/standby switchover and system upgrade to ensure uninterrupted forwarding of key services.

When the GR function is enabled, the forwarding plane continues data forwarding during a restart, and operations on the control plane, such as re-establishment of neighbor relationships and route calculation, do not affect the forwarding plane, preventing service interruption caused by route flapping and improving network reliability.

## Comparison Between the GR Mode and Non-GR Mode

**Table 1-73** Comparison between the OSPFv3 GR mode and non-GR mode

| Active/Standby Switchover in Non-GR Mode                                                                                                                                                                                                                                                                                                                           | Active/Standby Switchover in GR Mode                                                                                                                                                                                                                                                                                                                                                                       |

## OSPFv3 VPN

### Definition

As an extension to OSPFv3, OSPFv3 VPN multi-instance enables Provider Edges (PEs) and Customer Edges (CEs) in VPN scenarios to run OSPFv3 to learn and advertise routes.

### Purpose

As a widely used IGP, in most cases, OSPFv3 runs in VPNs. If OSPFv3 runs between PEs and CEs, and PEs use OSPFv3 to advertise VPN routes to CEs, no other routing protocols need to be configured on CEs for interworking with PEs, which simplifies management and configuration of CEs.

### Running OSPFv3 Between PEs and CEs

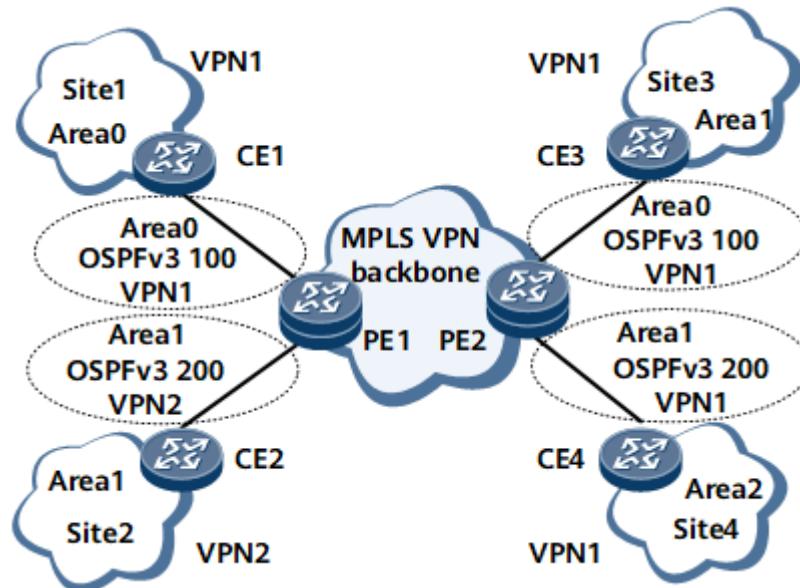

In BGP/MPLS IP VPN, Multi-Protocol BGP (MP-BGP) is used to transmit routing information between PEs, while OSPFv3 is used to learn and advertise routes between PEs and CEs.

Running OSPFv3 between PEs and CEs features the following benefits:

- OSPFv3 is used in a site to learn routes. Running OSPFv3 between PEs and CEs can reduce the number of protocol types supported by CEs.
- Similarly, running OSPFv3 both in a site and between PEs and CEs simplifies the work of network administrators and reduces the number of protocols that network administrators must be familiar with.
- When the network, which originally uses OSPFv3 but not VPN on the backbone network begins to use BGP/MPLS IP VPN, running OSPFv3 between PEs and CEs facilitates the transition.

In [Figure 1-161](#), CE1, CE3, and CE4 belong to VPN 1, and the numbers following OSPFv3 indicate the process IDs of the multiple OSPFv3 instances running on PEs.

**Figure 1-161** Running OSPFv3 between PEs and CEs

CE1 advertises routes to CE3 and CE4 as follows:

1. PE1 imports OSPFv3 routes of CE1 into BGP and forms BGP VPNv6 routes.
2. PE1 uses MP-BGP to advertise the BGP VPNv6 routes to PE2.
3. PE2 imports the BGP VPNv6 routes into OSPFv3 and then advertises these routes to CE3 and CE4.

The processes of advertising routes of CE4 and CE3 to CE1 are the same.

## OSPFv3 Domain ID

If inter-area routes are advertised between local and remote OSPFv3 areas, these areas are considered to be in the same OSPFv3 domain.

- Domain IDs identify and differentiate different domains.
- Each OSPFv3 domain has one or more domain IDs. If more than one domain ID is available, one of the domain IDs is a primary ID, and the others are secondary IDs.
- If an OSPFv3 instance does not have specific domain IDs, its ID is considered as null.

Before advertising the remote routes sent by BGP to CEs, PEs need to determine the type of OSPFv3 routes (Type 3 or Type 5) to be advertised to CEs based on the domain IDs, as shown in **Table 1-74**.

- If local domain IDs are the same as or compatible with the remote domain IDs in BGP routes, Type 3 routes are advertised.
- If local domain IDs are different from or incompatible with the remote domain IDs carried in BGP routes, Type 5 routes are advertised.

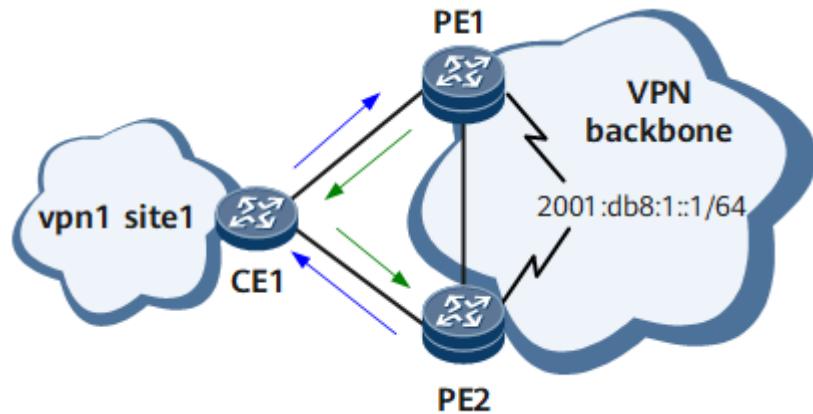

**Table 1-74** Domain ID

| Comparison Between Local and Remote Domain IDs                                                                            | Equal or Not | Route Type                                                                                                                  |
|---------------------------------------------------------------------------------------------------------------------------|--------------|-----------------------------------------------------------------------------------------------------------------------------|
| Both are null.                                                                                                            | Equal        | Inter-area routes                                                                                                           |
| The remote domain ID equals the local primary domain ID or the remote domain ID or one of the local secondary domain IDs. | Equal        | Inter-area routes                                                                                                           |
| The remote domain ID is different from the local primary domain ID or any of the local secondary domain IDs.              | Not equal    | If the local area is a non-NSSA, external routes are generated.<br>If the local area is an NSSA, NSSA routes are generated. |

## Routing Loop Prevention

Routing loops may occur between PEs and CEs when OSPFv3 and BGP learn routes from each other.

Figure 1-162 OSPFv3 VPN routing loops

As shown in [Figure 1-162](#), OSPFv3 on PE1 imports a BGP route destined for 2001:db8:1::1/64, generates a Type 5 or Type 7 LSA, and advertises the LSA to CE1. CE1 learns an OSPFv3 route with the destination address being 2001:db8:1::1/64 and the next hop being PE1, and advertises the route to PE2. In this way, PE2 learns the OSPFv3 route with 2001:db8:1::1/64 as the destination address and CE1 as the next hop.

Similarly, CE1 learns an OSPFv3 route with the destination address being 2001:db8:1::1/64 and next hop being PE2. In this way, PE1 learns the OSPFv3 route with 2001:db8:1::1/64 as the destination address and CE1 as the next hop.

CE1 has two equal-cost routes, with one destined for PE1 and the other destined for PE2. The next hops of the routes from PE1 and PE2 to 2001:db8:1::1/64 are CE1. As a result, a loop occurs.

As OSPFv3 routes have a higher priority than BGP routes, BGP routes to 2001:db8:1::1/64 are replaced by OSPFv3 routes on PE1 and PE2. That is, the OSPFv3 route that is destined for 2001:db8:1::1/64 and has CE1 as the next hop is active in the routing tables of PE1 and PE2.

The BGP route is inactive, and therefore, the LSA generated when this route is imported by OSPFv3 is deleted, which causes the OSPFv3 route to be withdrawn. As a result, no OSPFv3 route exists in the routing table, and the BGP route becomes active again. This cycle causes route flapping.

OSPFv3 VPN provides a few solutions to routing loops, as described in [Table 1-75](#).

**Table 1-75** Routing loop prevention

| Feature Name  | Definition                                                                                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                       |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DN-bit        | OSPFv3 multi-instance processes use a bit flag called the DN bit to prevent routing loops.                                                                                                                                                                                       | When advertising the generated Type 3, Type 5, or Type 7 LSAs to CEs, PEs set the DN-bit of these LSAs to 1 and the DN-bit of other LSAs to 0.<br><br>When calculating routes, the OSPFv3 multi-instance process of the PE ignores LSAs with the DN bit 1. This avoids routing loops that occur when PEs learn the self-originated LSAs from CEs. |
| VPN Route Tag | The VPN route tag is carried in the Type5 or Type7 LSA generated by PEs according to the received BGP private route.<br><br>It is not carried in BGP extended community attributes. The VPN route tag is valid only on the PEs that receive BGP routes and generate OSPFv3 LSAs. | When a PE detects that the VPN route tag in the incoming LSA is the same as that in the local LSA, the PE ignores this LSA to avoid routing loops.                                                                                                                                                                                                |
| Default route | A route with the destination address and mask of all 0s is a default route.                                                                                                                                                                                                      | PEs do not calculate default routes.<br><br>Default routes forward traffic from CEs or sites where CEs reside to the VPN backbone network.                                                                                                                                                                                                        |

## Multi-VPN-Instance CE

OSPFv3 multi-instance generally runs on PEs. Devices that run OSPFv3 multi-instance within user LANs are called Multi-VPN-Instance CEs (MCEs).

Compared with OSPFv3 multi-instance running on PEs, MCEs have the following characteristics:

- MCEs do not need to support OSPFv3-BGP association.
- MCEs establish one OSPFv3 instance for each service. Different virtual CEs transmit different services, which ensures LAN security at a low cost.
- MCEs implement different OSPFv3 instances on a CE. The key to implementing MCEs is to disable loop detection and calculate routes directly.

That is, MCEs also use the received LSAs with the DN bit set to 1 for route calculation.

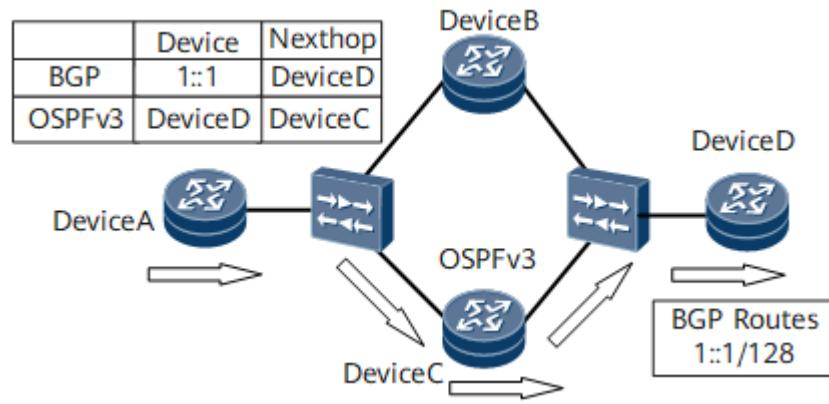

## OSPFv3-BGP Association

New device deployment or a device restart may lead to network traffic loss during BGP convergence. This is due to IGP convergence being faster than BGP convergence. OSPFv3-BGP association can address this problem.

After a device on a BGP network recovers from a fault, BGP convergence is performed again and packet loss may occur during the convergence.

As shown in [Figure 1-163](#), traffic from DeviceA to DeviceD traverses a BGP network through DeviceC.

**Figure 1-163** Traffic traversing a BGP network

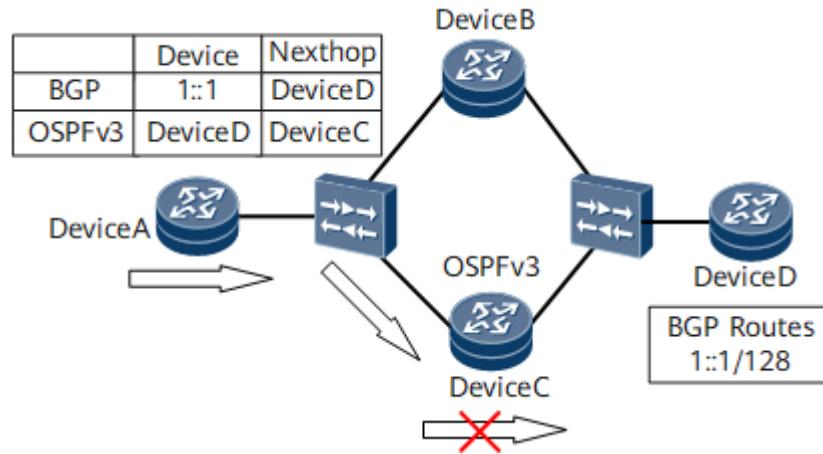

If DeviceC fails, traffic passes through DeviceB due to route reselection. Packets are lost when DeviceC recovers.

Because OSPFv3 route convergence is faster than BGP route convergence, OSPFv3 convergence completes first when DeviceC recovers. On DeviceA, the next hop of the route to DeviceD is DeviceC. However, BGP convergence on DeviceC is not complete. As a result, DeviceC does not know how to reach DeviceD.

In this manner, when traffic from DeviceA to DeviceD is sent to DeviceC, DeviceC discards the traffic because it does not have the route to DeviceD, as shown in [Figure 1-164](#).

**Figure 1-164** Packet loss upon device restart without OSPFv3-BGP association

## Process of OSPFv3-BGP Association

A device enabled with OSPFv3-BGP association sets the maximum link cost (65535) in its LSA to ensure that the device is not used as a traversal device. BGP routes, however, can still reach the device.

As shown in [Figure 1-163](#), OSPFv3-BGP association is enabled on DeviceC. Before BGP convergence is complete, DeviceA does not forward traffic to DeviceC. Instead, DeviceA continues to use the backup link (passing through DeviceB) until BGP routes on DeviceC are converged.

## OSPFv3 Authentication

### OSPFv3 IPsec Authentication

The rapid development of networks poses higher requirements for network security. Routing protocol packets that are transmitted on networks may be intercepted, changed, or forged, and packet attacks may cause network interruption. Therefore, packets need to be protected.

The standard protocol does not define the authentication mechanism for OSPFv3. Therefore, OSPFv3 packets do not carry any authentication information. However, the standard protocol defines the IPsec mechanism to authenticate OSPFv3 packets.

The IPsec protocol family, which consists of a series of protocols defined by the Internet Engineering Task Force (IETF), provides high-quality, interoperable, and cryptology-based security for IP packets. By encrypting data and authenticating the data source at the IP layer, communicating parties can ensure confidentiality, data integrity, data authentication, and anti-replay for the data transmitted across the network.

 NOTE

- Confidentiality: The data is encrypted and transmitted in cipher text.
- Data integrity: Received data is authenticated to check whether they have been modified.
- Data authentication: The data source is authenticated to ensure that the data is sent from a real sender.
- Anti-replay: The attacks from malicious users who repeatedly send obtained data packets are prevented. Specifically, the receiver rejects old or repeated data packets.

IPsec adopts two security protocols: Authentication Header (AH) and Encapsulating Security Payload (ESP).

- AH: A protocol that provides data origin authentication, data integrity check, and anti-replay protection. AH does not encrypt packets to be protected.  
AH data is carried in the following fields:
  - Version number
  - Packet header length
  - Packet length
  - Authentication
  - Protocol
  - Source and destination addresses
  - Options
- ESP: A protocol that provides IP packet encryption mechanism besides the functions provided by AH. The encryption and authentication mechanisms can be used together or independently.

## OSPFv3 Authentication Trailer

Prior to the OSPFv3 Authentication Trailer, OSPFv3 can use only IPsec for authentication. However, on some special networks, a mobile ad hoc network (MANET) for example, IPsec is difficult to deploy and maintain. To address this problem, Authentication Trailer for OSPFv3 can be used to implement authentication.

OSPFv3 authentication encrypts OSPFv3 packets by adding the authentication field to packets to ensure network security. A local device checks the authentication field in OSPFv3 packets received from a remote device, and discards the packets if they do not contain the same authentication password as the locally configured one, thereby achieving self-protection.

In terms of authentication scope, OSPFv3 authentication is classified as follows:

- Area authentication  
This authentication mode is configured in the OSPFv3 area view and applies to packets received by all interfaces in the OSPFv3 area.
- Process authentication  
This authentication mode is configured in the OSPFv3 view and applies to all packets in the OSPFv3 process.
- Interface authentication

This authentication mode is configured in the interface view and applies to all packets received by the interface.

OSPFv3 uses HMAC-SHA256 to authenticate packets. In HMAC-SHA256 authentication, a configured password is hashed using the HMAC-SHA256 algorithm, and the ciphertext password is added to packets for authentication. This authentication mode improves password security.

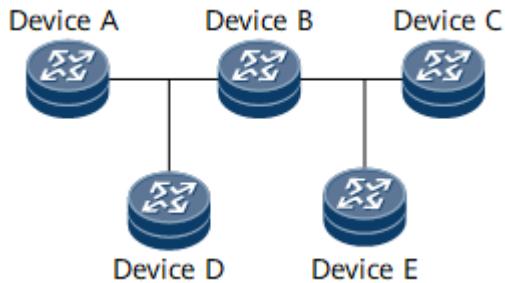

OSPFv3 carries authentication types in packet headers and authentication information in packet trailers.

The authentication types are as follows:

- 1: Simple authentication
- 2: Ciphertext authentication

## Networking Application of OSPFv3 Authentication Trailer

Figure 1-165 OSPFv3 authentication trailer on a broadcast network

Configuration requirements:

- The interface authentication configurations must be the same on all devices on the same network so that OSPFv3 neighbor relationships can be established.
- Area authentication configurations must be the same on all devices in the same area.

## OSPFv3 Neighbor Relationship Flapping Suppression

OSPFv3 neighbor relationship flapping suppression works by delaying OSPFv3 neighbor relationship reestablishment or setting the link cost to the maximum value.

## Background

If an interface carrying OSPFv3 services frequently alternates between up and down, frequent neighbor relationship flapping will occur. During the flapping, OSPFv3 frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, OSPFv3 services, and other OSPFv3-dependent services, such as LDP and BGP. OSPFv3 neighbor relationship flapping suppression can address this problem by delaying

OSPFv3 neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

## Related Concepts

**flapping\_event**: reported when the status of a neighbor relationship on an interface last changes from Full to a non-Full state. The flapping\_event triggers flapping detection.

**flapping\_count**: number of times flapping has occurred.

**detect-interval**: detection interval. The interval is used to determine whether to trigger a valid flapping\_event.

**threshold**: flapping suppression threshold. When the flapping\_count reaches or exceeds **threshold**, flapping suppression takes effect.

**resume-interval**: interval for exiting from OSPFv3 neighbor relationship flapping suppression. If the interval between two successive valid flapping\_events is longer than **resume-interval**, the flapping\_count is reset.

## Implementation

### Flapping detection

Each OSPFv3 interface on which OSPFv3 neighbor relationship flapping suppression is enabled starts a **flapping\_count**. If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than **detect-interval**, a valid flapping\_event is recorded, and the **flapping\_count** increases by 1. When the **flapping\_count** reaches or exceeds **threshold**, flapping suppression takes effect. If the interval between two successive neighbor status changes from Full to a non-Full state is longer than **resume-interval**, the **flapping\_count** is reset.

The **detect-interval**, **threshold**, and **resume-interval** are configurable.

#### NOTE

The value of **resume-interval** must be greater than that of **detect-interval**.

### Flapping suppression

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationships from being reestablished during the suppression period, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path changes frequently, interfaces use 65535 as the cost of the flapping link during Hold-max-cost suppression, which prevents traffic from passing through the flapping link.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, the Hold-max-cost mode takes effect. The mode and suppression duration can be changed manually.

If an attack causes frequent neighbor relationship flapping, Hold-down mode can minimize the impact of the attack.

 **NOTE**

When an interface enters the flapping suppression state, all neighbor relationships on the interface enter the state accordingly.

### Exiting from flapping suppression

Interfaces exit from flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding OSPFv3 process is reset.
- An OSPFv3 neighbor relationship is reset.
- A command is run to exit from flapping suppression.

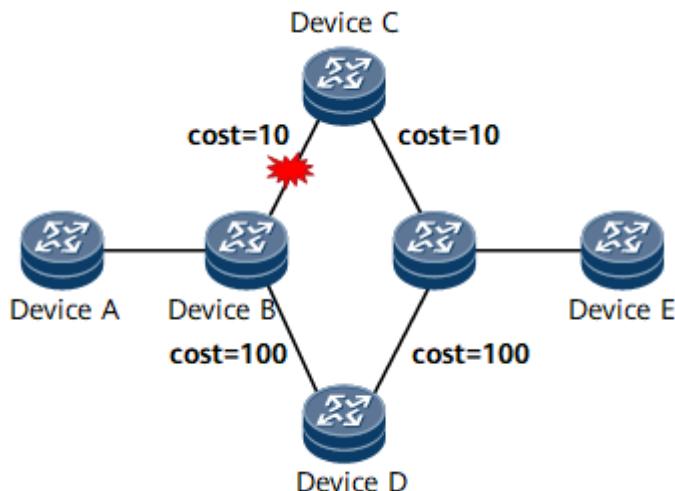

## Typical Scenarios

### Basic scenario

In [Figure 1-166](#), the traffic forwarding path is Device A -> Device B -> Device C -> Device E before a link failure occurs. After the link between Device B and Device C fails, the forwarding path switches to Device A -> Device B -> Device D -> Device E. If the neighbor relationship between Device B and Device C frequently flaps at the early stage of the path switchover, the forwarding path will be switched frequently, causing traffic loss and affecting network stability. If the neighbor flapping between Device B and Device C meets flapping suppression conditions, flapping suppression is triggered.

- If flapping suppression works in Hold-down mode, the neighbor relationship between Device B and Device C is prevented from being reestablished during the suppression period, in which traffic is forwarded along the path Device A -> Device B -> Device D -> Device E.
- If flapping suppression works in Hold-max-cost mode, 65535 is used as the cost of the link between Device B and Device C during the suppression period, and traffic is forwarded along the path Device A -> Device B -> Device D -> Device E.

**Figure 1-166** Flapping suppression in a basic scenario

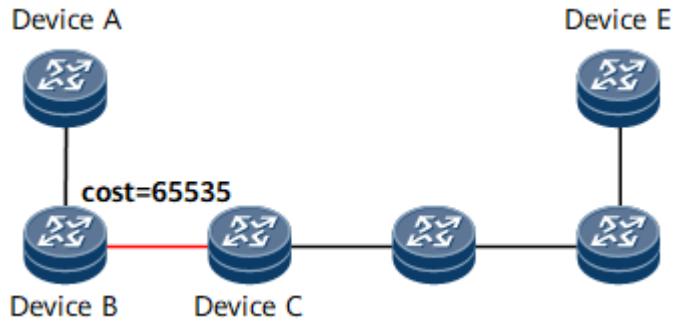

### Single-forwarding path scenario

When only one forwarding path exists on the network, the flapping of the neighbor relationship between any two devices on the path will interrupt traffic forwarding. In [Figure 1-167](#), the traffic forwarding path is Device A -> Device B -> Device C -> Device E. If the neighbor relationship between Device B and Device C flaps, and the flapping meets suppression conditions, flapping suppression takes effect. However, if the neighbor relationship between Device B and Device C is prevented from being reestablished, the whole network will be divided. Therefore, Hold-max-cost mode (rather than Hold-down mode) is recommended. If flapping suppression works in Hold-max-cost mode, 65535 is used as the cost of the link between Device B and Device C during the suppression period. After the network stabilizes and the suppression timer expires, the link is restored.

#### NOTE

By default, the Hold-max-cost mode takes effect.

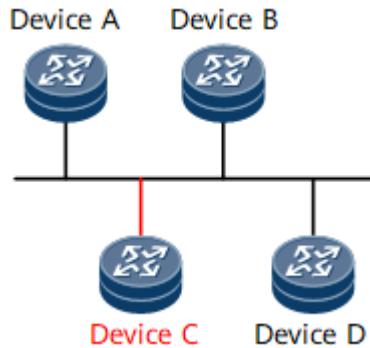

**Figure 1-167** Flapping suppression in a single-forwarding path scenario

### Broadcast scenario

In [Figure 1-168](#), four devices are deployed on the same broadcast network using switches, and the devices are broadcast network neighbors. If Device C flaps due to a link failure, and Device A and Device B were deployed at different time (Device A was deployed earlier for example) or the flapping suppression parameters on Device A and Device B are different, Device A first detects the flapping and suppresses Device C. Consequently, the Hello packets sent by Device A do not carry Device C's router ID. However, Device B has not detected the flapping yet and still considers Device C a valid node. As a result, the DR candidates identified by Device A are Device B and Device D, whereas the DR candidates identified by Device B are Device A, Device C, and Device D. Different DR candidates result in a different DR election result, which may lead to route calculation errors. In scenarios where an interface has multiple neighbors, such as on a broadcast, P2MP, or NBMA network, all neighbors on the interface are suppressed if the last flapping event that the neighbor status on the interface goes down is detected (flapping detection cannot be performed by neighbor). Specifically, if Device C flaps, Device A, Device B, and Device D on the broadcast network are all suppressed. After the network stabilizes and the suppression timer expires, Device A, Device B, and Device D are restored to normal status.

Figure 1-168 Flapping suppression on a broadcast network

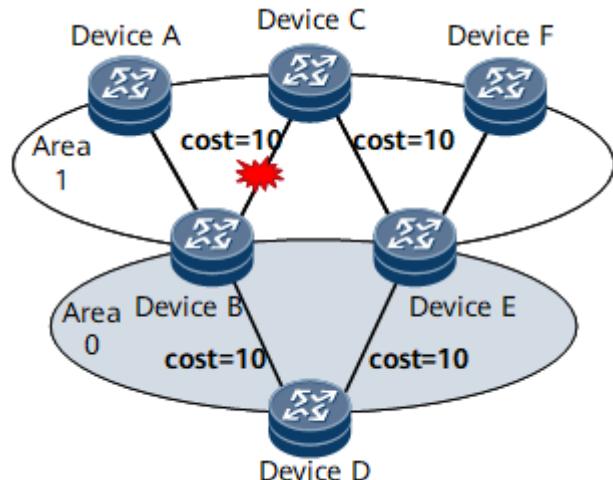

### Multi-area scenario

In [Figure 1-169](#), Device A, Device B, Device C, Device E, and Device F are connected in area 1, and Device B, Device D, and Device E are connected in backbone area 0. Traffic from Device A to Device F is preferentially forwarded along an intra-area route, and the forwarding path is Device A -> Device B -> Device C -> Device E -> Device F. If the neighbor relationship between Device B and Device C flaps and the flapping meets suppression conditions, flapping suppression takes effect in the default mode (Hold-max-cost). However, the forwarding path remains unchanged (Device A -> Device B -> Device C -> Device E -> Device F) after the neighbor flapping occurs because intra-area routes take precedence over inter-area routes during route selection regardless of costs according to OSPF route selection rules. The Hold-max-cost mode cannot suppress traffic path switching in this case. To prevent traffic loss in multi-area scenarios, configure Hold-down mode to prevent the neighbor relationship between Device B and Device C from being reestablished during the suppression period. During this period, traffic is forwarded along the path Device A -> Device B -> Device D -> Device E -> Device F.

#### NOTE

By default, the Hold-max-cost mode takes effect. The mode can be changed to Hold-down manually.

Figure 1-169 Flapping suppression in a multi-area scenario

## OSPFv3 Flush Source Tracing

### Context

If network-wide OSPFv3 LSA flush causes network instability, source tracing must be implemented as soon as possible to locate and isolate the fault source. However, OSPFv3 itself does not support source tracing. A conventional solution is isolation node by node until the faulty node is located. The solution is complex and time-consuming, which also affects user network services. To solve the preceding problem, OSPFv3 introduces a proprietary protocol, namely, the source tracing protocol. This protocol supports the flooding of flush source information. When the preceding problem occurs, you can quickly query the flush source information on any device on the network to quickly locate the fault source.

### Related Concepts

#### Source tracing

A mechanism that helps locate the device that flushes OSPFv3 LSAs. It has the following features:

- Uses a new UDP port. Source tracing packets are carried by UDP packets, and the UDP packets carry the OSPFv3 LSAs flushed by the current device and are flooded hop by hop based on the OSPFv3 topology.
- Depends on OSPFv3 neighbors for flooding and forwards packets along UDP channels, which are independent of the channels used to transmit OSPFv3 packets. Therefore, this protocol facilitates incremental deployment. In addition, source tracing does not affect the devices with the related UDP port disabled.
- Supports query of the node that flushed LSAs on any device that supports this feature after source tracing packets are flooded on the network, which speeds up fault locating and faulty node isolation by maintenance personnel.

#### Flush

Network-wide OSPFv3 LSAs are deleted.

#### PS-Hello packets

Packets used to negotiate the OSPFv3 flush source tracing capability between OSPFv3 neighbors.

#### PS-LSA

When a device flushes an OSPFv3 LSA, it generates a PS-LSA carrying information about the device and brief information about the OSPFv3 LSA.

#### PS-LSU packets

OSPFv3 flush source tracing packets that carry PS-LSAs.

#### PS-LSU ACK packets

Acknowledgment packets used to enhance the reliability of OSPFv3 flush source tracing packets.

#### OSPFv3 flush source tracing port

ID of the UDP port that receives and sends OSPFv3 flush source tracing packets.  
The ID is configurable.

## Fundamentals

OSPFv3 flush source tracing is implemented as follows:

1. Source tracing capability negotiation

After an OSPFv3 neighbor relationship is established between two devices, they need to negotiate the source tracing capability through PS-Hello packets.

2. PS-LSA generation and flooding

When a device flushes an OSPFv3 LSA, it generates a PS-LSA carrying information about the device and brief information about the OSPFv3 LSA, adds the PS-LSA to a PS-LSU packet, and floods the PS-LSU packet to source tracing-capable neighbors, which helps other devices locate the fault source and perform isolation.

 NOTE

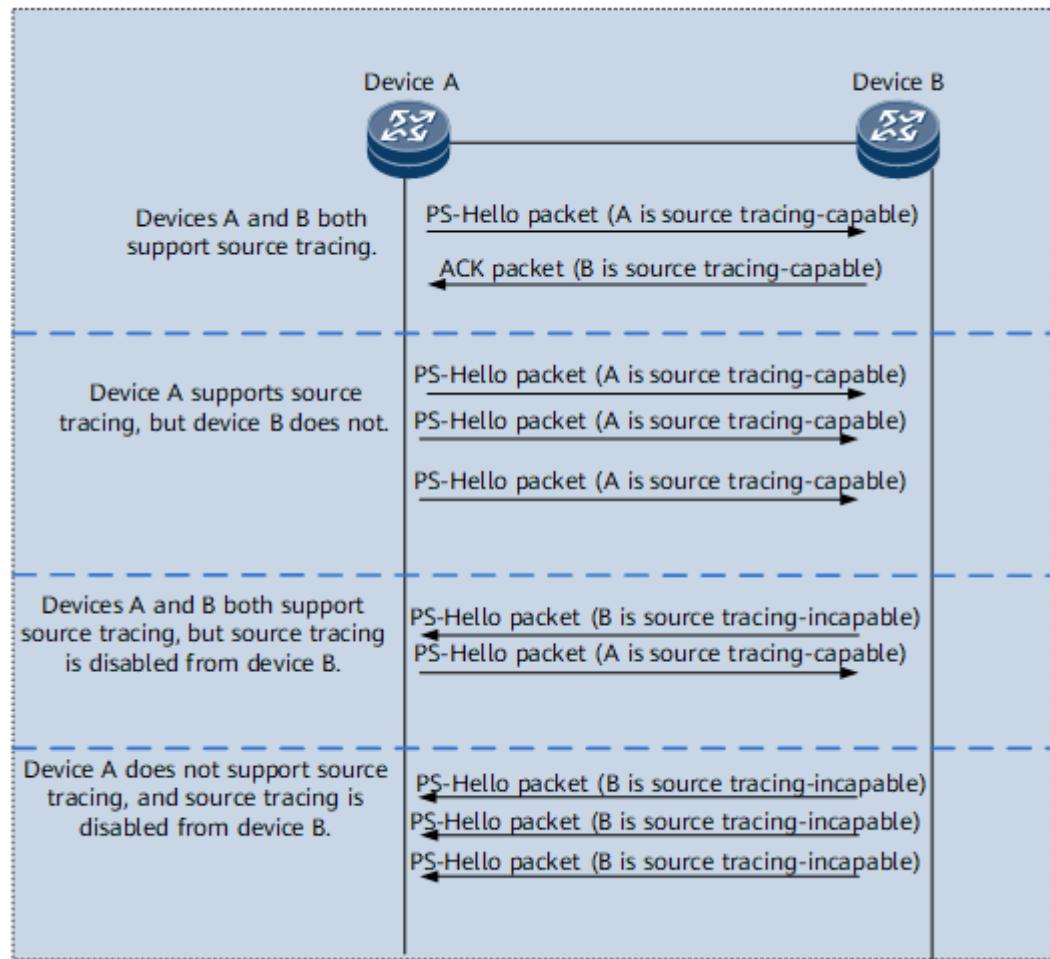

Only router-LSAs, network-LSAs, and inter-area-router-LSAs can be flushed. Therefore, a device generates a PS-LSA only when it flushes a router-LSA, network-LSA, or inter-area-router-LSA.

## Source Tracing Capability Negotiation

The source tracing protocol uses UDP to carry the proprietary protocol packets and listens to the UDP port to receive and send source tracing packets. If a source tracing-capable Huawei device sends source tracing packets to a source tracing-incapable Huawei device or non-Huawei device, the source tracing-capable Huawei device may be incorrectly identified as an attacker. Therefore, the source tracing capability needs to be negotiated between the devices. In addition, the source tracing-capable device needs to send source tracing information on behalf of the source tracing-incapable device, which also requires negotiation.

Source tracing depends on OSPFv3. Therefore, source tracing negotiation depends on OSPFv3 neighbor relationships. Specifically, after an OSPFv3 neighbor relationship is established, the local device initiates source tracing capability negotiation. [Figure 1-170](#) shows the negotiation process.

**Figure 1-170** Source tracing capability negotiation

**Table 1-76** Source tracing capability negotiation

| Whether Source Tracing Is Supported          | Source Tracing Capability Negotiation Process                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

After two retransmissions, DeviceB considers the capability negotiation complete and disables the UDP port.</li> </ol>                               |

## PS-LSA Generation and Flooding

PS-LSA: carries information about the node that flushed OSPFv3 LSAs.

- If a device flushes an LSA, it generates and floods a PS-LSA to source tracing-capable neighbors.
- If a device receives a flush LSA from a source tracing-incapable neighbor, the device generates and floods a PS-LSA to source tracing-capable neighbors. If a device receives the same flush LSA (with the same LSID and sequence number) from more than one source tracing-incapable neighbors, the device generates only one PS-LSA.
- If a device flushes a router-LSA, network-LSA, or inter-area-router-LSA, it generates a PS-LSA, adds the PS-LSA to a PS-LSU packet, and floods the PS-LSU packet to all source tracing-capable neighbors.

Figure 1-171 PS-LSA generation rules

### PS-LSA generation rules

- When DeviceA flushes a router-LSA, network-LSA, or inter-area-router-LSA, it generates a PS-LSA in which the **Flush Router** field is its router ID and the **Neighbor Router** field is 0, and adds the PS-LSA to the queue where packets are to be sent to all source tracing-capable neighbors.
- After DeviceA receives the flush LSA from source tracing-incapable DeviceB, DeviceA generates a PS-LSA in which the **Flush Router** field is its router ID and the **Neighbor Router** field is the router ID of DeviceB, and adds the PS-LSA to the queue where packets are to be sent to all source tracing-capable neighbors.
- After DeviceA receives the flush LSA from DeviceB, followed by the same flush LSA sent by DeviceC, DeviceA generates a PS-LSA in which the **Flush Router** field is its router ID and the **Neighbor Router** field is the router ID of DeviceB, and adds the PS-LSA to the queue where packets are to be sent to all source tracing-capable neighbors. No PS-LSA is generated in response to the flush LSA received from DeviceC.

### PS-LSU packet sending rules

- During neighbor relationship establishment, a device initializes the sequence number of the PS-LSU packet of the neighbor. When the device replies with a PS-LSU packet, it adds the sequence number of the PS-LSU packet of the neighbor. During PS-LSU packet retransmission, the sequence number remains unchanged. After the device receives a PS-LSU ACK packet with the same sequence number, it increases the sequence number of the neighbor's PS-LSU packet by 1.
- The neighbor manages the PS-LSA sending queue. When a PS-LSA is added to the queue which was empty, the neighbor starts a timer. After the timer expires, the neighbor adds the PS-LSA to a PS-LSU packet, sends the packet to its neighbor, and starts another timer to wait for a PS-LSU ACK packet.
- After the PS-LSU ACK timer expires, the PS-LSU packet is retransmitted.
- When the device receives a PS-LSU ACK packet with a sequence number same as that in the neighbor record, the device clears PS-LSAs from the neighbor queue, and sends another PS-LSU packet after the timer expires.
  - If the sequence number of a received PS-LSU ACK packet is less than that in the neighbor record, the device ignores the packet.
  - If the sequence number of a received PS-LSU ACK packet is greater than that in the neighbor record, the device discards the packet.

 NOTE

PS-LSU packet sending is independent among neighbors.

**PS-LSU packet receiving rules**

- When a device receives a PS-LSU packet from a neighbor, the neighbor records the sequence number of the packet and replies with a PS-LSU ACK packet.
- When the device receives a PS-LSU packet with the sequence number the same as that in the neighbor record, the device discards the PS-LSU packet.
- After the device parses a PS-LSU packet, it adds the PS-LSA in the packet to the LSDB. The device also checks whether the PS-LSA is newer than the corresponding PS-LSA in the LSDB.
  - If the received PS-LSA is newer, the device floods it to other neighbors.
  - If the received PS-LSA is the same as the corresponding local one, the device does not process the received PS-LSA.
  - If the received PS-LSA is older, the device floods the corresponding PS-LSA in the LSDB to the neighbor.
- If the device receives a PS-LSU packet from a neighbor and the neighbor does not support source tracing, the device modifies the neighbor status as source tracing capable.

## Source Tracing Security

The source tracing protocol uses UDP packets, and a private port needs to be enabled to send and receive protocol packets. Therefore, the security of the port must be considered.

The source tracing protocol inevitably increases packet receiving and sending workload and intensifies bandwidth pressure. To minimize its impact on original protocols and reduce the traffic of source tracing packets, the number of source tracing packets must be controlled.

Table 2 describes source tracing security measures.

**Table 1-77** Security measures for source tracing

| Security Measures for Source Tracing | Fundamentals                                                                                                                                                |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authentication                       | Source tracing is embedded in OSPFv3, inherits existing OSPFv3 configuration parameters, and uses OSPFv3 authentication parameters to authenticate packets. |

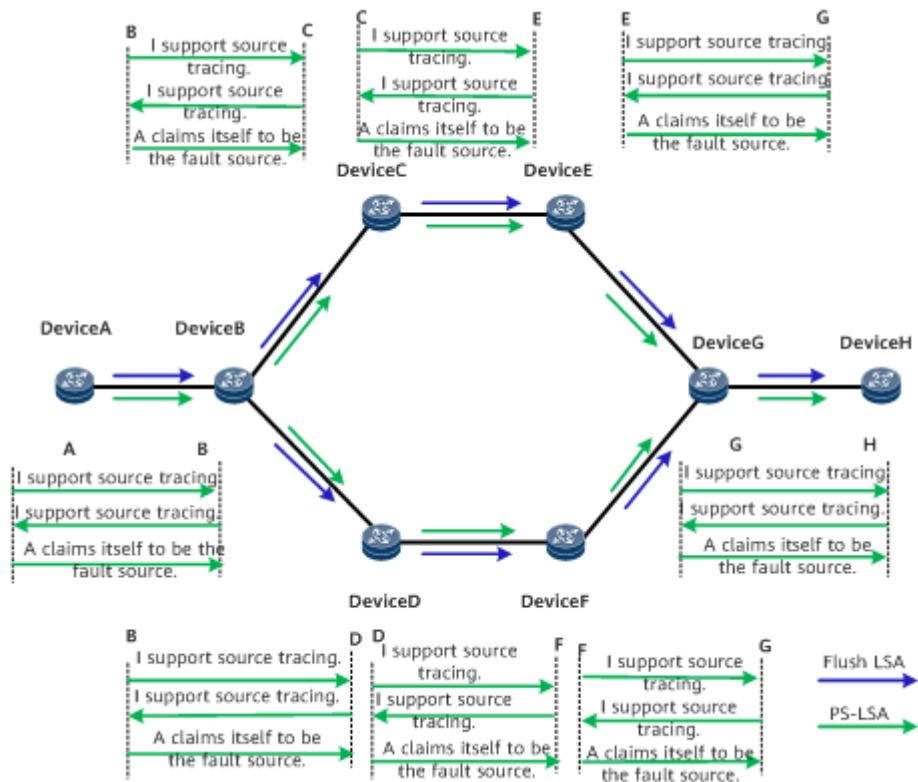

| Security Measures for Source Tracing | Fundamentals                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GTSM                                 | <p>GTSM is a security protocol that checks whether the time to live (TTL) value in each sent and received IP packet is within a pre-defined range.</p> <p>Source tracing packets can only be flooded as far as one hop. Therefore, GTSM can be used to check such packets by default.</p> <ul style="list-style-type: none"><li>• When a device sends a packet, it sets the TTL of the packet to 255.</li><li>• If the TTL is not 254 when the packet is received, the packet will be discarded.</li></ul> |
| CPU-CAR                              | <p>Interface boards can check the packets to be sent to the CPU for processing and prevent the main control board from being overloaded by a large number of packets that are sent to the CPU. The source tracing protocol needs to apply for an independent CAR channel and has small CAR values configured.</p>                                                                                                                                                                                          |

## Typical Scenarios

### Scenario where all nodes support source tracing

Assume that all nodes on the network support source tracing and DeviceA is the fault source. In this scenario, the fault source can be accurately located. [Figure 1-172](#) shows the networking.

**Figure 1-172 Scenario where all nodes support source tracing**

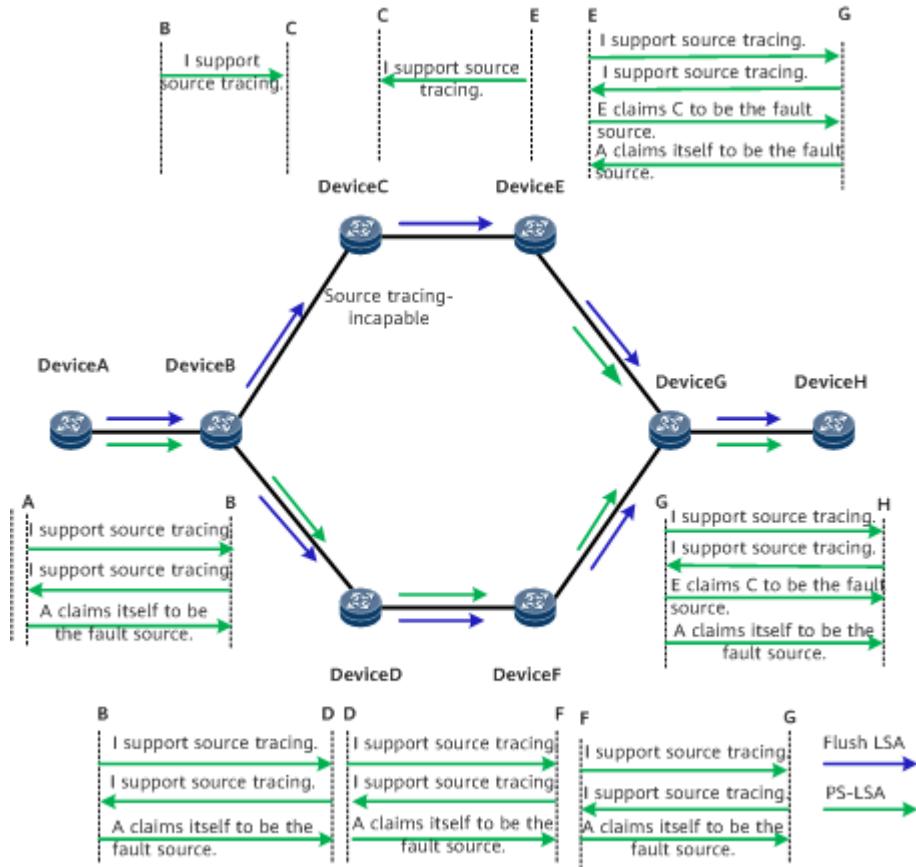

When DeviceA flushes an OSPFv3 LSA, it generates a PS-LSA that carries DeviceA information and brief information about the OSPFv3 flush LSA. Device A then floods the PS-LSA. After the fault occurs, maintenance personnel can log in to any node on the network to locate DeviceA, which keeps sending flush LSAs, and isolate DeviceA from the network.

#### Scenario where source tracing-incapable nodes are not isolated from source tracing-capable nodes

All nodes on the network except DeviceC support source tracing, and DeviceA is the fault source. In this case, the PS-LSA can be flooded on the entire network, and the fault source can be accurately located. [Figure 1-173](#) shows the networking.

**Figure 1-173 Scenario where source tracing-incapable nodes are not isolated from source tracing-capable nodes**

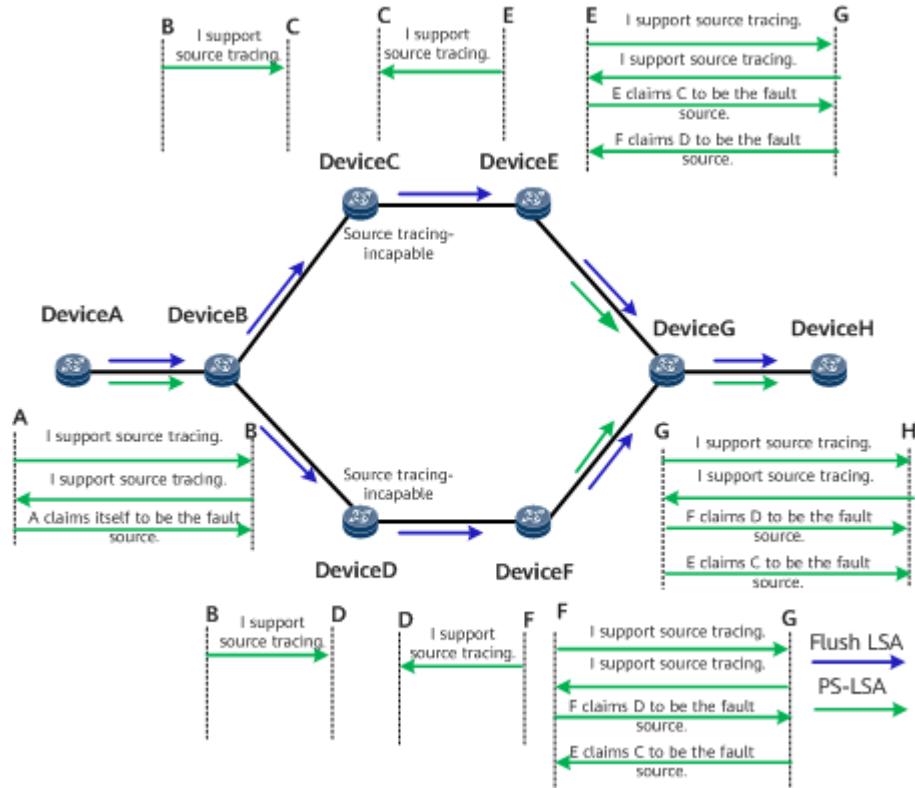

When DeviceA flushes an OSPFv3 LSA, it generates a PS-LSA that carries DeviceA information and brief information about the OSPFv3 flush LSA. Device A then floods the PS-LSA. When DeviceB and DeviceE negotiate the source tracing capability with DeviceC, they find that DeviceC does not support source tracing. Therefore, after DeviceB receives the PS-LSA from DeviceA, DeviceB sends the PS-LSA to DeviceD, but not to DeviceC. Device A sends a flush LSA to Device B. When Device C sends the flush LSA to Device E, Device E finds that Device C does not support source tracing, helps Device C generate a PS-LSA that carries information about the advertisement source (Device E) and flush source (Device C), and flushed OSPFv3 LSA, and floods the PS-LSA on the entire network.

After the fault occurs, maintenance personnel can log in to any device on the network except DeviceC to locate the fault source. Two possible fault sources can be located in this case. One fault source is advertised by Device A, which claims that it has initiated a large number of flush packets. The other fault source is advertised by Device E and it claims that Device C may initiate a large number of flush packets. Both Device A and Device C flush the same LSA. In this case, DeviceA takes precedence over DeviceC. Therefore, Device A is the fault source and measures are taken to isolate Device A. After DeviceA is isolated, the network recovers.

#### Scenario where source tracing-incapable nodes are isolated from source tracing-capable nodes

All nodes on the network except DeviceC and DeviceD support source tracing, and DeviceA is the fault source. In this case, the PS-LSA cannot be flooded on the entire network, and the fault source can only be found within a certain range. [Figure 1-174](#) shows the networking.

**Figure 1-174** Scenario where source tracing-incapable nodes are isolated from source tracing-capable nodes

When DeviceA flushes an OSPFv3 LSA, it generates a PS-LSA that carries DeviceA information and brief information about the OSPFv3 flush LSA. Device A then floods the PS-LSA. However, the PS-LSA can reach only DeviceB because DeviceC and DeviceD do not support source tracing.

During source tracing capability negotiation, DeviceE finds that DeviceC does not support source tracing, and DeviceF finds that DeviceD does not support source tracing. After DeviceE receives the flush LSA from DeviceC, DeviceE generates and floods a PS-LSA on behalf of DeviceC. Similarly, after DeviceF receives the flush LSA from DeviceD, DeviceF generates and floods a PS-LSA on behalf of DeviceD.

After the fault occurs:

- If maintenance personnel log in to DeviceA or DeviceB, the personnel can locate the fault source (DeviceA) directly. After DeviceA is isolated, the network recovers.
- If the maintenance personnel log in to DeviceE, DeviceF, DeviceG, or DeviceH, the personnel will find that DeviceE claims DeviceC to be the fault source of the OSPFv3 flush LSA and DeviceF claims DeviceD to be the fault source of the same OSPFv3 flush LSA.

- If the maintenance personnel log in to DeviceC and DeviceD, the personnel will find that the flush LSA was initiated by DeviceB, not generated by DeviceC or DeviceD.
- If the maintenance personnel log in to DeviceB, the personnel will find that DeviceA is the fault source, and isolate DeviceA. After DeviceA is isolated, the network recovers.

## Routing Loop Detection for Routes Imported to OSPFv3

Routes of an OSPFv3 process can be imported to another OSPFv3 process or the process of another protocol (such as IS-IS or BGP) for redistribution. However, if a device that performs such a route import is incorrectly configured, routing loops may occur. OSPFv3 can use the routing loop detection function to detect routing loops.

## Related Concepts

### Redistribute ID

IS-IS uses a system ID as a redistribution identifier, OSPF and OSPFv3 use a router ID + process ID as a redistribution identifier, and BGP uses a VrfID + random number as a redistribution identifier. For ease of understanding, the redistribution identifiers of different protocols are all called Redistribute IDs. When routes are distributed, the information carried in the routes contains Redistribute IDs.

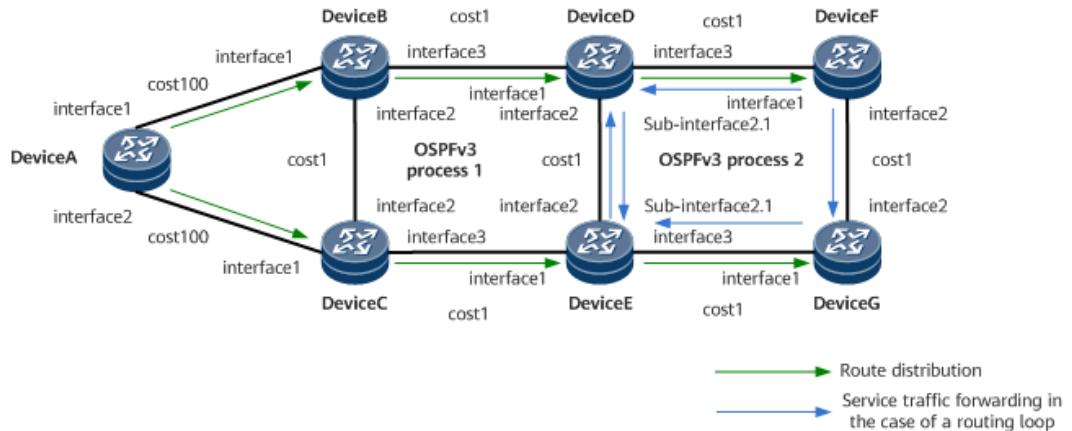

### Redistribute List

A Redistribute list may consist of multiple Redistribute IDs. Each Redistribute list of BGP contains a maximum of four Redistribute IDs, and each Redistribute list of any other routing protocol contains a maximum of two Redistribute IDs. When the number of Redistribute IDs exceeds the corresponding limit, the old ones are discarded according to the sequence in which Redistribute IDs are added.

## Background (OSPFv3 Inter-Process Mutual Route Import)

On the network shown in [Figure 1-175](#), DeviceA, DeviceB, and DeviceC run OSPFv3 process 1; DeviceF and DeviceG run OSPFv3 process 2; DeviceD and DeviceE run both of the processes. Route import between OSPFv3 process 1 and OSPFv3 process 2 is configured on DeviceD and DeviceE. The routes distributed by OSPFv3 process 1 on DeviceE are re-distributed back to OSPFv3 process 1 on DeviceD through OSPFv3 process 2. As the costs of the routes newly distributed by DeviceD are smaller, they are preferentially selected by OSPFv3 process 1, resulting in routing loops.

**Figure 1-175** Typical network diagram of OSPFv3 inter-process mutual route import

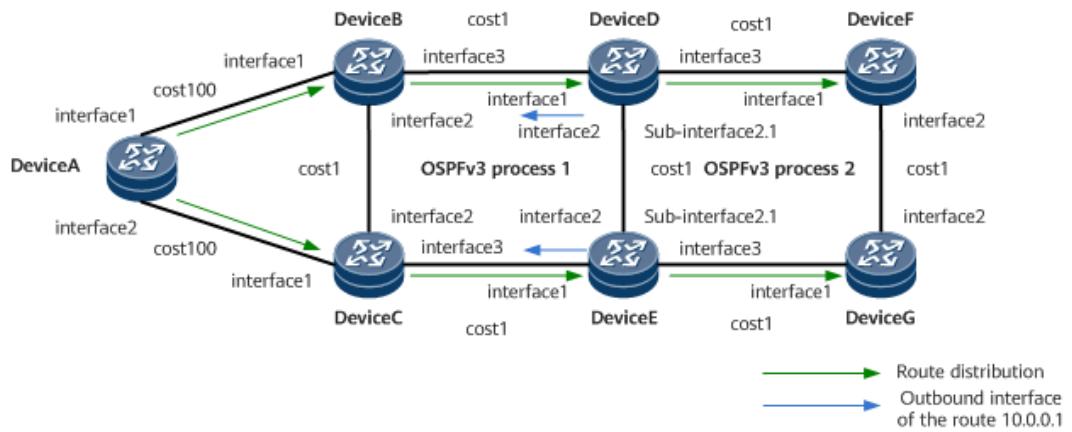

Take the route distributed by DeviceA as an example. A stable routing loop is formed through the following process:

### Phase 1

On the network shown in [Figure 1-176](#), OSPFv3 process 1 on DeviceA imports the static route 10.0.0.1 and floods a Type 5 AS-External-LSA in OSPFv3 process 1. After receiving the LSA, OSPFv3 process 1 on DeviceD and OSPFv3 process 1 on DeviceE each calculate a route to 10.0.0.1, with the outbound interfaces being interface1 on DeviceD and interface1 on DeviceE, respectively, and the cost being 102. At this point, the routes to 10.0.0.1 in OSPFv3 process 1 in the routing tables of DeviceD and DeviceE are active.

**Figure 1-176** Phase 1

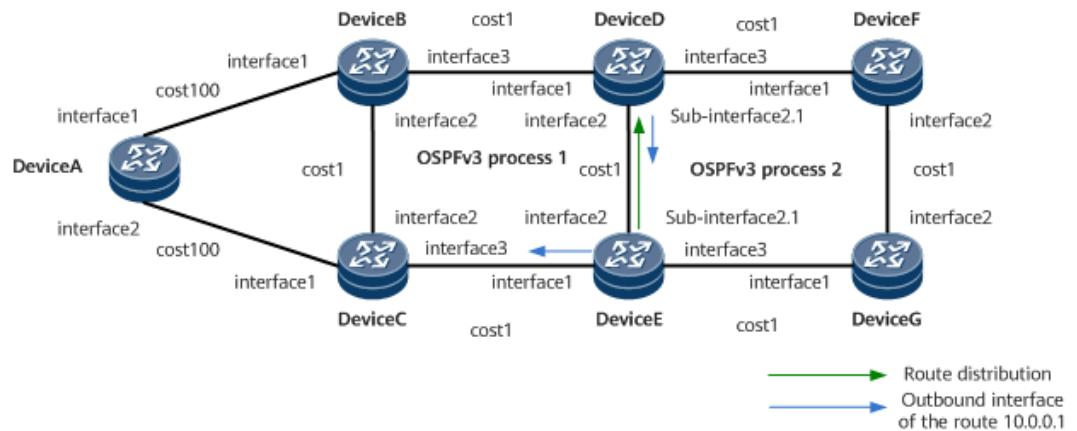

### Phase 2

In [Figure 1-177](#), DeviceD and DeviceE are configured to import routes from OSPFv3 process 1 to OSPFv3 process 2. No route-policy is configured for the import, or the configured route-policy is improper. For example, OSPFv3 process 2 on DeviceE imports routes from OSPFv3 process 1 and then floods a Type 5 AS-External-LSA in OSPFv3 process 2. After receiving the LSA, OSPFv3 process 2 on DeviceD calculates a route to 10.0.0.1, with the cost being 2, which is smaller than that (102) of the route calculated by OSPFv3 process 1. As a result, the active

route to 10.0.0.1 in the routing table of DeviceD is switched from the one calculated by OSPFv3 process 1 to the one calculated by OSPFv3 process 2, and the outbound interface of the route is sub-interface2.1.

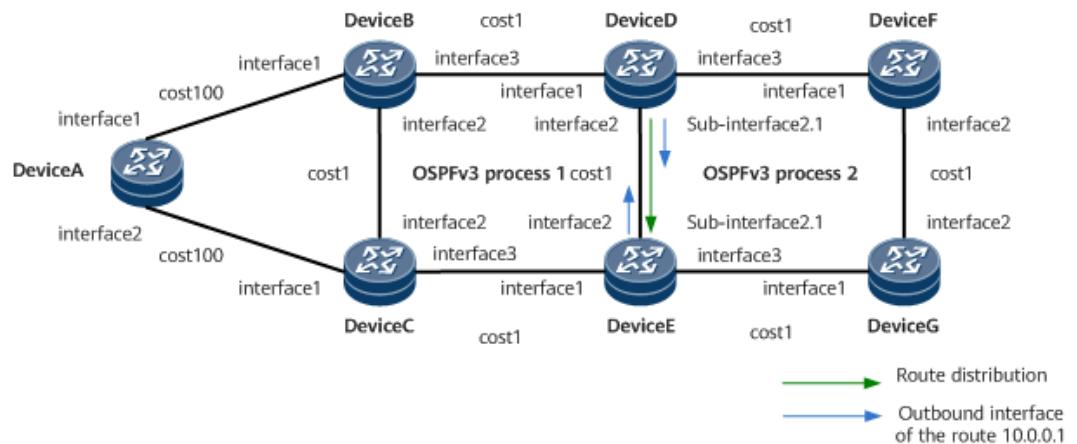

**Figure 1-177 Phase 2**

### Phase 3

In [Figure 1-178](#), DeviceD imports the route from OSPFv3 process 2 to OSPFv3 process 1 and floods a Type 5 AS-External LSA in OSPFv3 process 1. After receiving the LSA, OSPFv3 process 1 on DeviceE recalculates the route to 10.0.0.1. The cost of the route becomes 2, which is smaller than that of the previously calculated route. Therefore, the route to 10.0.0.1 in OSPFv3 process 1 on DeviceE is changed to the route distributed by DeviceD, and the outbound interface is interface 2.

**Figure 1-178 Phase 3**

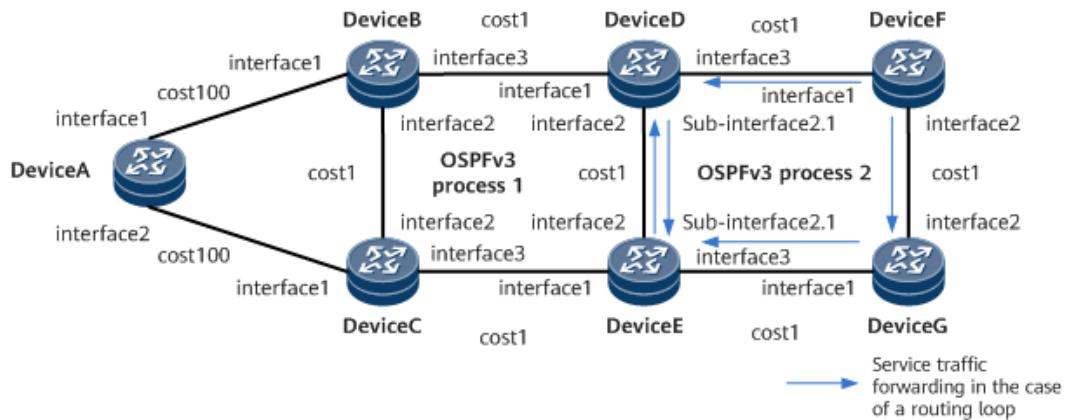

### Phase 4

After the route to 10.0.0.1 on DeviceE is updated, OSPFv3 process 2 still imports the route from OSPFv3 process 1 as the route remains active, and continues to distribute/update a Type 5 AS-External-LSA.

As a result, a stable routing loop is formed. Assuming that traffic is injected from DeviceF, [Figure 1-179](#) shows the traffic flow when the routing loop occurs.

**Figure 1-179** Traffic flow when a routing loop occurs

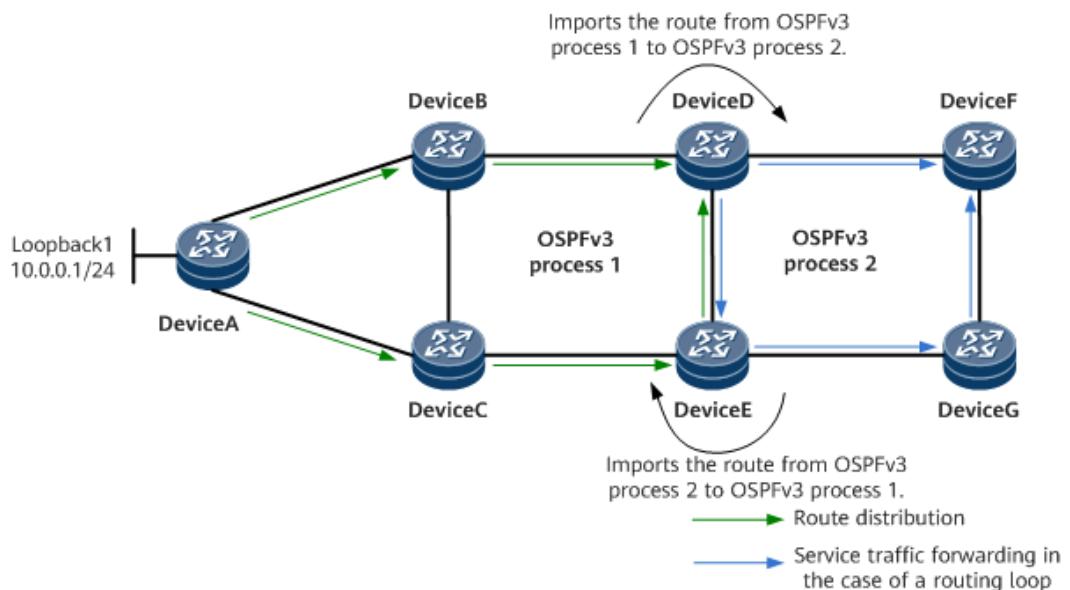

## Implementation (OSPFv3 Inter-Process Mutual Route Import)

Routing loop detection for the routes imported between OSPFv3 processes can resolve the routing loops in the preceding scenario.

When distributing a Type 5 AS-External LSA for an imported route, OSPFv3 also uses an E-AS-External-LSA to distribute to other devices the Redistribute ID of the device that redistributes the imported route. If the route is redistributed by different protocols through multiple devices, all the Redistribute IDs of these protocols on the devices are distributed through an E-AS-External-LSA. When receiving the E-AS-External-LSA, a route calculation device saves the Redistribute ID and route information of the route redistribution device. When another process of a route calculation device imports the route, the device checks whether a routing loop occurs according to the route redistribution information. If a routing loop occurs, the device attaches a large route cost to the AS-External-LSA for the imported route so that other devices preferentially select other paths after learning the route. This prevents routing loops.

**Figure 1-180** Typical networking of route import to OSPFv3

**Figure 1-180** is used to describe how a routing loop is detected and resolved.

1. DeviceA distributes its locally originated route 10.0.0.1/24 to DeviceB.
2. DeviceD learns the route distributed by DeviceB through OSPFv3 process 1 and imports the route from OSPFv3 process 1 to OSPFv3 process 2. DeviceE learns the route distributed by DeviceD through OSPFv3 process 2 and saves the Redistribute List distributed by DeviceD through OSPFv3 process 2 to the routing table when calculating routes.
3. DeviceE imports the route from OSPFv3 process 2 to OSPFv3 process 1 and redistributes the route through OSPFv3 process 1. The corresponding E-AS-External-LSA contains the Redistribute ID of OSPFv3 process 1 on DeviceE and the Redistribute ID of OSPFv3 process 2 on DeviceD. The Redistribute ID of OSPFv3 process 1 on DeviceB has been discarded from the LSA.
4. OSPFv3 process 1 on DeviceD learns the Redistribute list corresponding to the route distributed by DeviceE and saves the Redistribute list in the routing table. When importing the route from OSPFv3 process 1 to OSPFv3 process 2, DeviceD finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. OSPFv3 process 2 on DeviceD distributes a large cost when redistributing the route so that other devices preferentially select other paths after learning the route. This prevents routing loops.

 **NOTE**

In the preceding typical networking:

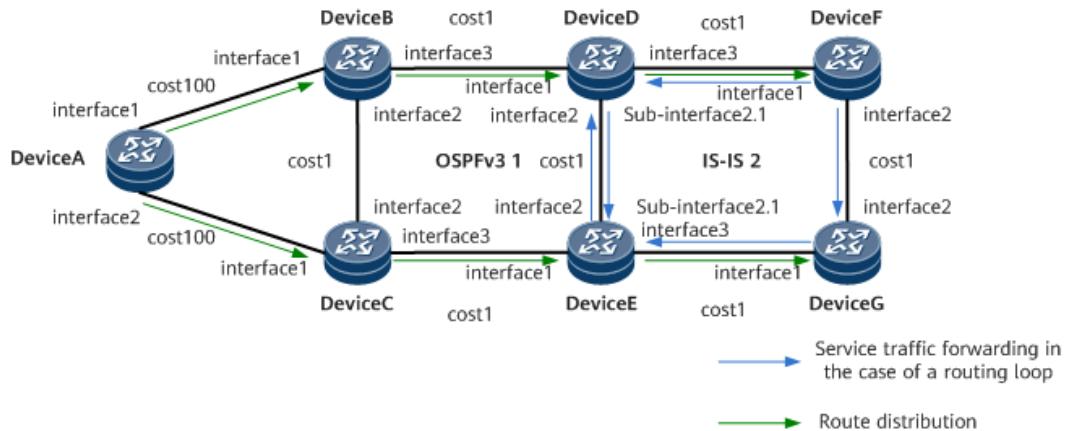

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

## Background (Mutual Route Import Between OSPFv3 and IS-IS)

On the network shown in **Figure 1-181**, DeviceA, DeviceB, and DeviceC run OSPFv3 process 1, DeviceF and DeviceG run IS-IS process 2, and DeviceD and DeviceE run both processes. Route import between OSPFv3 process 1 and IS-IS process 2 is configured on DeviceD and DeviceE. The routes distributed by OSPFv3 process 1 on DeviceE are re-distributed back to OSPFv3 process 1 on DeviceD through IS-IS process 2. As the costs of the routes newly distributed by DeviceD are smaller, they are preferentially selected by OSPFv3 process 1, resulting in routing loops.

**Figure 1-181** Traffic flow when a routing loop occurs during route import between OSPFv3 and IS-IS

## Implementation (Mutual Route Import Between OSPFv3 and IS-IS)

The following uses the networking shown in [Figure 1-181](#) as an example to describe how a routing loop is detected and resolved.

1. DeviceD learns the route distributed by DeviceB through OSPFv3 process 1 and imports the route from OSPFv3 process 1 to IS-IS process 2. When IS-IS process 2 on DeviceD distributes route information, it uses the extended prefix sub-TLV to distribute the Redistribute ID of IS-IS process 2 through an LSP. IS-IS process 2 on DeviceE learns the route distributed by DeviceD and saves the Redistribute ID distributed by IS-IS process 2 on DeviceD to the routing table during route calculation.
2. DeviceE imports the route from IS-IS process 2 to OSPFv3 process 1 and uses an E-AS-External-LSA to distribute the Redistribute ID of OSPFv3 process 1 on DeviceE when redistributing the imported route. Similarly, after OSPFv3 process 1 on DeviceD learns the route from DeviceE, DeviceD saves the Redistribute ID distributed by OSPFv3 process 1 on DeviceE to the routing table during route calculation.
3. When importing the route from OSPFv3 process 1 to IS-IS process 2, DeviceD finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. IS-IS process 2 on DeviceD distributes a large cost when distributing the imported route. Because IS-IS has a higher preference than OSPFv3 ASE, this does not affect the route selection result or resolve the routing loop.
4. DeviceE imports the route from IS-IS process 2 to OSPFv3 process 1, finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. OSPFv3 process 1 on DeviceE distributes a large cost when distributing the imported route so that other devices preferentially select other paths after learning the route. This prevents routing loops.

 NOTE

In the preceding typical networking:

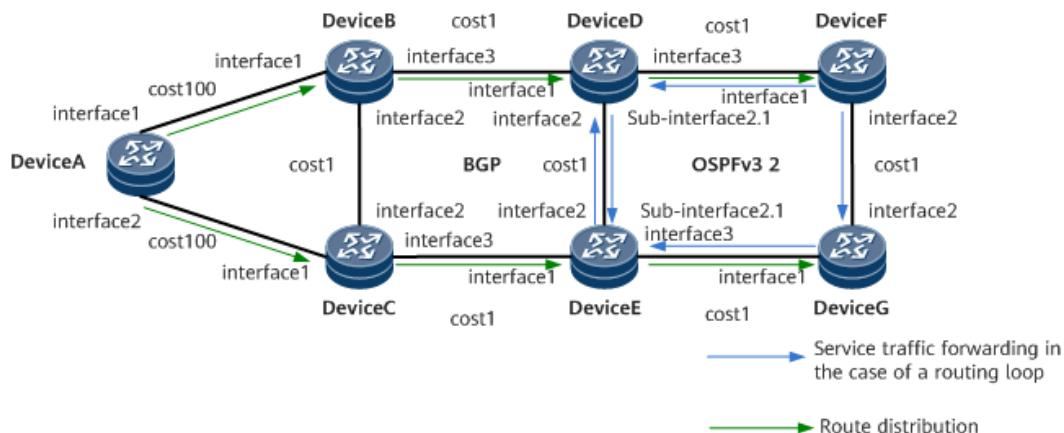

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

## Background (Mutual Route Import Between OSPFv3 and BGP)

On the network shown in [Figure 1-182](#), DeviceA, DeviceB, and DeviceC run a BGP process, DeviceF and DeviceG run OSPFv3 process 2, and DeviceD and DeviceE run both processes. Route import between BGP and OSPFv3 process 2 is configured on DeviceD and DeviceE. The routes distributed by BGP on DeviceE are redistributed back to BGP through OSPFv3 process 2 on DeviceD. Because no route-policy is configured for the import or the configured route-policy is improper, the route newly distributed by DeviceD may be selected as the optimal route by BGP, causing a routing loop.

**Figure 1-182** Traffic flow when a routing loop occurs during route import between OSPFv3 and BGP

## Implementation (Mutual Route Import Between OSPFv3 and BGP)

The following uses the networking shown in [Figure 1-182](#) as an example to describe how a routing loop is detected and resolved.

1. DeviceD learns the route distributed by DeviceB through BGP and imports the BGP route to OSPFv3 process 2. When DeviceD distributes the imported route through OSPFv3 process 2, it uses an extended prefix E-AS-External-LSA to distribute the Redistribute ID of OSPFv3 process 2 on DeviceD. DeviceE learns the route distributed by DeviceD through OSPFv3 process 2 and saves the Redistribute List distributed by DeviceD through OSPFv3 process 2 to the routing table when calculating routes.

2. DeviceE imports the route from OSPFv3 process 2 to BGP and distributes the Redistribute ID of the BGP process on DeviceE through an E-AS-External-LSA when redistributing the imported route. After BGP on DeviceD learns the route distributed by DeviceE, DeviceD saves the Redistribute ID distributed by BGP on DeviceE to the routing table during route calculation.
3. When importing the route from BGP to OSPFv3 process 2, DeviceD finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. OSPFv3 process 2 on DeviceD distributes a large link cost when distributing the imported route. Because OSPFv3 has a higher preference than BGP, this does not affect the route selection result or resolve the routing loop.
4. When importing the route from OSPFv3 process 2 to BGP, DeviceE finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. In addition, when BGP on DeviceE distributes the imported route, it reduces the preference of the route. In this way, other devices preferentially select other paths after learning this route, preventing routing loops.

 NOTE

In the preceding typical networking:

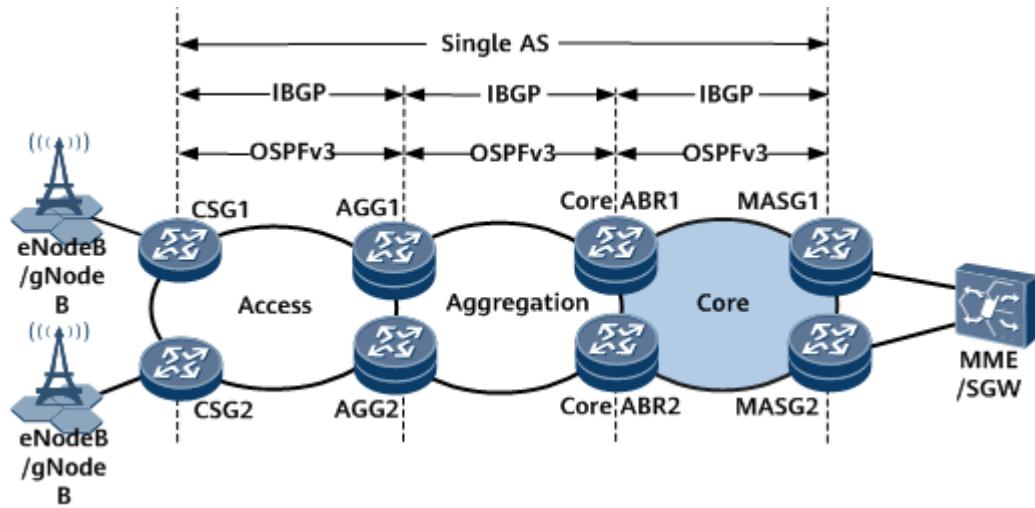

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

## Usage Scenario

**Figure 1-183** shows a typical seamless MPLS network. If the OSPFv3 process deployed at the access layer differs from that deployed at the aggregation layer, OSPFv3 inter-process mutual route import is usually configured on AGGs so that routes can be leaked between the access and aggregation layers. As a result, a routing loop may occur between AGG1 and AGG2. If routing loop detection for OSPFv3 is configured on AGG1 and AGG2, routing loops can be quickly detected and other routes can be preferentially selected, preventing routing loops.

**Figure 1-183** Routing protocol deployment on the intra-AS seamless MPLS network

### 1.1.5.2 OSPFv3 Configuration

This chapter describes the key concepts of Open Shortest Path First version 3 (OSPFv3) and provides an overview of its configuration and maintenance. OSPFv3 is applicable to large-scale networks with hundreds of devices.

#### 1.1.5.2.1 OSPFv3 Overview

OSPFv3 uses the same basic implementation mechanism as OSPFv2 but is incompatible with OSPFv2.

#### Definition

Open Shortest Path First (OSPF) is a link-state Interior Gateway Protocol (IGP) developed by the Internet Engineering Task Force (IETF).

OSPF version 2 (OSPFv2) is intended for IPv4, and OSPF version 3 (OSPFv3) is intended for IPv6.

- OSPFv3 is short for OSPF version 3.
- OSPFv3 runs over IPv6.
- OSPFv3 is an enhanced version of OSPFv2 but is an independent routing protocol.

#### Purpose

OSPFv3 is an extension of OSPF for support of IPv6.

### 1.1.5.2.2 Configuration Precautions for OSPFv3

#### Feature Requirements

**Table 1-78** Feature requirements

| Feature Requirements                                                                                                                                                                                                                                                                                                                                          | Series           | Models                                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|----------------------------------------------------------------------------------------------------|
| OSPFv3 checks whether a neighbor in the full state exists in the backbone area before advertising a default route to the stub area.                                                                                                                                                                                                                           | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/<br>NetEngine 8000 X16/NetEngine 8000E X8/<br>NetEngine 8100 X |
| The network types of the interfaces on both ends of an OSPFv3 neighbor relationship must be the same so that the interfaces can learn routes after the neighbor relationship is established. Otherwise, the neighbor relationship cannot be established and routes cannot be calculated.<br><br>You are advised to use the same network type at both ends.    | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/<br>NetEngine 8000 X16/NetEngine 8000E X8/<br>NetEngine 8100 X |
| If the OSPFv3 neighbor timeout period is too short, the neighbor relationship may go Down due to timeout, affecting services.<br><br>You are advised to use the default hello timer and dead timer, or change the dead timer to a value greater than or equal to 40s.                                                                                         | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/<br>NetEngine 8000 X16/NetEngine 8000E X8/<br>NetEngine 8100 X |
| After the device is restarted, if the BFD session status of the local device or neighbor is AdminDown, the OSPFv3 status is not affected. When the BFD session is renegotiated, if BFD reports the detection status Down but the previous detection status is Up, OSPFv3 sets the neighbor status to Down. In other cases, the OSPFv3 status is not affected. | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/<br>NetEngine 8000 X16/NetEngine 8000E X8/<br>NetEngine 8100 X |

| Feature Requirements                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Series           | Models                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|--------------------------------------------------------------------------------------------|

### 1.1.5.2.3 Configuring Basic OSPFv3 Functions

To construct an OSPFv3 network, configure basic OSPFv3 functions first.

#### Usage Scenario

OSPFv3 functions take effect only after an OSPFv3 process, the router ID, the interface, and the area ID are specified.

OSPFv3 functions can be configured in the interface view, regardless of whether OSPFv3 is enabled. If OSPFv3 is disabled from the interface, OSPFv3 functions configured on this interface are still valid.

## Pre-configuration Tasks

Before configuring basic OSPFv3 functions, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- Enable IPv6.

## (Optional) Configuring OSPFv3 Short-Timeout Neighbor Enhancement

OSPFv3 short-timeout neighbor enhancement improves neighbor stability in scenarios where there are many short-timeout neighbors.

## Context

If the configured interval at which an interface sends Hello packets is less than 10s, many OSPFv3 short-timeout neighbors may exist. (For details about setting the interval, see [Setting the Interval at Which Hello Packets Are Sent](#).) In this case, if the device has poor performance, and the CPU usage is high or a switchover is performed, the neighbors may be unstable due to scheduling issues. To improve the stability of short-timeout neighbors in scenarios where there are more than 150 OSPF and OSPFv3 short-timeout neighbors, you can configure the short-timeout neighbor enhancement function, which increases the OSPFv3 short-timeout neighbor specification.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run ospf short-timeout neighbor enhancement

OSPFv3 short-timeout neighbor enhancement is configured.

#### NOTE

- If the device has more than 150 short-timeout neighbors and this function is configured or deleted when the CPU usage is high, the neighbors may be intermittently disconnected. If this function is required, you are advised to perform this step before [configuring an OSPFv3 process](#).
- After this step is performed, short-timeout neighbor enhancement takes effect for both OSPF and OSPFv3.

### Step 3 Run commit

The configuration is committed.

----End

## Enabling OSPFv3

Creating an OSPFv3 process is a prerequisite for configuring OSPFv3 features. When creating an OSPFv3 process, you need to manually specify a router ID for it.

## Context

OSPFv3 supports multi-process. Multiple OSPFv3 processes running on one device are differentiated by process IDs. An OSPFv3 process ID is set when an OSPFv3 process is created. The process ID is only locally valid and does not affect packet exchange with other devices.

A router ID is a 32-bit unsigned integer in the format of an IPv4 address. It uniquely identifies a device in an AS. The OSPFv3 router ID must be manually set, and OSPFv3 cannot run properly without a router ID.

When configuring the router ID, ensure that the router ID is unique in an AS. If multiple OSPFv3 processes run on the same device, you are advised to specify different router IDs for the processes.

To ensure OSPFv3 stability, plan router IDs properly during network design and manually set the router IDs during network deployment.

Perform the following steps on each device that needs to run OSPFv3:

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ] [ vpn-instance vpnnname ]**

OSPFv3 is enabled, and the OSPFv3 view is displayed.

You can run the **description** command to configure a description for an OSPFv3 process for easier identification.

### Step 3 Run **router-id router-id**

A router ID is set.

When configuring the router ID, ensure that the router ID is unique in an AS. You can select the IP address of an interface as the router ID.

#### NOTE

Each router ID in an OSPFv3 process must be unique on the entire network. Otherwise, routers cannot establish OSPFv3 neighbor relationships, and the routing information is incorrect.

If a router ID conflict occurs, perform either of the following operations:

- Configure a new router ID.
- Run the **undo ospfv3 router-id auto-recover disable** command to enable the router ID automatic recovery function. After the function is enabled, the system automatically allocates a new router ID.

 NOTE

- If the automatic recovery function is enabled and a router ID conflict occurs between indirectly connected routers in one OSPFv3 area, the system replaces the conflicted router ID with a newly calculated one. The automatic recovery function takes effect on both configured and automatically generated router IDs.
- The system can replace a router ID in a maximum of three attempts in case the router ID conflict persists.

**Step 4 Run commit**

The configuration is committed.

----End

## Enabling OSPFv3 on an Interface

For an interface with multiple instances, you need to specify which instance on the interface is enabled in the OSPFv3 process when enabling OSPFv3 on the interface.

### Context

After enabling OSPFv3 in the system view, you need to enable OSPFv3 on the interface.

Because an interface may have multiple instances, you need to specify which instance of the interface is enabled in the OSPFv3 process when OSPFv3 is enabled on the interface. If no instance ID is specified, the value defaults to 0. The same instance must be enabled on the interfaces between which the neighbor relationship is set up.

Perform the following steps on the router that runs OSPFv3.

## Procedure

**Step 1 Run system-view**

The system view is displayed.

**Step 2 Run `interface interface-type interface-number`**

The interface view is displayed.

**Step 3 Run `ospfv3 process-id area area-id [ instance instance-id ]`**

OSPFv3 is enabled on the interface.

The specified area ID can be a decimal integer or in the IPv4 address format. Regardless of the specified format, the area ID is displayed as an IPv4 address.

**Step 4 (Optional) Run `ospfv3 network-type { broadcast | nbma | p2mp [ non-broadcast ] | p2p } [ instance instance-id ]`**

A network type is configured for the interface.

When an interface supports multi-instance, specify `instance-id` when enabling OSPFv3 on the interface. If `instance-id` is not specified, the default value 0 is

adopted. In this case, the configured network type of the interface is different from the actual network type. This step is mandatory in such a case.

**Step 5 Run commit**

The configuration is committed.

----End

## Creating an OSPFv3 Area

After an AS is divided into different areas and OSPFv3 interfaces and areas to which these interfaces belong are specified, OSPFv3 can discover and calculate routes in the AS.

## Procedure

**Step 1 Run system-view**

The system view is displayed.

**Step 2 Run ospfv3 [ *process-id* ]**

The OSPFv3 view is displayed.

**Step 3 Run area *area-id***

The OSPFv3 area view is displayed.

The area ID can be a decimal integer or in the IPv4 address format, but it is displayed in the IPv4 address format.

The description of an OSPFv3 area helps identify special processes by the **description** command.

**Step 4 Run commit**

The configuration is committed.

----End

## (Optional) Configuring the router to Comply with Route Selection Rules Defined in a Standard Protocol

You can configure the router to comply with the route selection rule defined in RFC 1583 or RFC 5340.

## Context

RFC 5340 and RFC 1583 define route selection rules differently. After enabling OSPFv3 on a device, you can configure the device to comply with route selection rules defined in either standard protocol as required. By default, a device complies with the route selection rules defined in RFC 5340. If you want the device to comply with the other protocol, you need to configure the device to comply with the rules defined in RFC 1583. Such configurations ensure that all OSPFv3-enabled devices in an AS comply with the same route selection rules defined in the same standard protocol.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ] [ vpn-instance vpnnname ]**

OSPFv3 is enabled, and the OSPFv3 view is displayed.

### Step 3 Run **rfc1583 compatible**

The router is configured to comply with the route selection rule defined in RFC 1583, rather than RFC 5340.

### Step 4 Run **commit**

The configuration is committed.

----End

## (Optional) Configuring an Alarm Threshold for the Number of LSAs Learned by OSPFv3

You can configure an alarm threshold for the number of LSAs learned by OSPFv3 so that an alarm is reported when this threshold is reached or exceeded.

## Context

If the number of external routes that OSPFv3 imports and advertises exceeds the routing table capacity of a device, the device may restart unexpectedly. To prevent this problem and ensure that the device runs properly, you can set an alarm threshold for the number of LSAs learned by OSPFv3 and enable overload control.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **maximum received-lsa threshold value [ overload-limit ]**

An alarm threshold is configured for the number of LSAs learned by OSPFv3. You can determine whether to enable overload control as required.

- If an alarm threshold is configured but overload control is not, only an alarm is reported when this threshold is reached or exceeded.
- If both an alarm threshold and overload control are configured, an alarm is reported when this threshold is reached or exceeded. In addition, OSPFv3 no longer learns new LSAs when the following conditions are met:
  - The number of LSAs learned by OSPFv3 reaches or exceeds the alarm threshold.
  - The memory is in the danger state, and the memory used by the OSPFv3 LSDB component ranks in the top 3.

- The **ospf memory-overload control** command configuration exists (The corresponding function is enabled by default).

#### Step 4 Run **commit**

The configuration is committed.

----End

### (Optional) Configuring the Maximum Number of Packet Retransmission Attempts

When no response to DD packets, Update packets, or Request packets is received, the retransmission mechanism is used and the maximum number of packet retransmission attempts is set to prevent dead loops caused by repeated transmissions.

#### Context

If no response is received when the maximum number of packet retransmission attempts is reached, the neighbor relationship will be interrupted.

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

##### Step 3 Run **retransmission-limit [ max-number ]**

The maximum number of OSPFv3 packet retransmission attempts is set.

##### Step 4 Run **commit**

The configuration is committed.

----End

### (Optional) Disabling an Interface from Receiving and Sending OSPFv3 Packets

Disabling an interface from receiving and sending OSPFv3 packets prevents other network devices from obtaining OSPFv3 routing information and prevents the local device from receiving routing updates advertised by other network devices.

#### Context

To prevent a device interface from sending its OSPFv3 routing information to other devices on the network and disable the device interface from receiving routing updates from other devices, you can suppress the interface from sending and receiving OSPFv3 packets. After an interface is disabled from receiving and sending OSPFv3 packets, the interface can still advertise its routes but cannot exchange Hello packets with others. Therefore, no neighbor relationship can be established between the interface and others. This can enhance the networking adaptability of OSPFv3 and reduce system resource consumption.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run ospfv3 [ *process-id* ]

The OSPFv3 process view is displayed.

### Step 3 Run silent-interface *interface-type interface-number*

The interface is disabled from receiving and sending OSPFv3 packets.

#### NOTE

In different processes, you can suppress the same interface from sending and receiving OSPFv3 packets. However, the **silent-interface** configuration takes effect only in the specified process of an interface, not all processes associated with the interface.

### Step 4 Run commit

The configuration is committed.

----End

## Verifying the Basic OSPFv3 Configuration

After configuring basic OSPFv3 functions, verify information about neighbors, interfaces, and the OSPFv3 routing table.

## Prerequisites

Basic OSPFv3 functions have been configured.

## Procedure

- Run the **display ospfv3 [ *process-id* ] [ area *area-id* ] peer [ *interface-type interface-number* ] [ verbose ]** command in any view to view information about OSPFv3 neighbors.
- Run the **display ospfv3 [ *process-id* ] [ area *area-id* ] [ *interface-type interface-number* ]** command in any view to view information about an OSPFv3 interface.
- Run the **display ospfv3 [ *process-id* ] routing** command in any view to view information about an OSPFv3 routing table.
- Run the **display ospfv3 [ *process-id* ] cumulative** command in any view to view OSPFv3 statistics.
- Run the **display ospfv3 [ *process-id* ] error [ lsa | interface *interface-type interface-number* ]** command in any view to view OSPFv3 errors.
- Run the **display ospfv3 [ *process-id* ] next-hop** command in any view to view the OSPFv3 next-hop routing table.
- Run the **display ospfv3 [ *process-id* ] request-list [ statistics | [ area *area-id* | peer *router-id* | interface *interface-type interface-number* ] \* ]** command in any view to view the statistics of the request list of OSPFv3.

- Run the **display ospfv3 [ process-id ] retrans-list [ statistics | { area area-id } peer router-id | interface interface-type interface-number } \* ]** command in any view to view the statistics of the OSPFv3 retransmission list.
- Run the **display ospfv3 [ process-id ] spf-statistics [ verbose ]** command in any view to view OSPFv3 route calculation statistics.
- Run the **display ospfv3 [ process-id ] statistics updated-lsa [ originate-router advertising-router-id | history ]** command in any view to view the frequent updates of the Link State Advertisements (LSAs) that the Link-state Database (LSDB) receives.
- Run the **display ospfv3 [ process-id ] topology [ area area-id ] [ statistics | verbose ]** command in any view to view information about the topology in an OSPFv3 area.

----End

#### 1.1.5.2.4 Configuring OSPFv3 Attributes on Different Types of Networks

By setting network types for OSPFv3 interfaces and adjusting OSPFv3 attributes, you can build OSPFv3 networks flexibly.

#### Usage Scenario

Based on the types of link layer protocols, OSPFv3 classifies networks into the following types:

- P2MP: Because P2MP is not a link layer protocol, each P2MP network is changed from a network of another type.
- NBMA: If the link layer protocol is X.25, OSPFv3 defaults the network type to NBMA.
- Broadcast: If the link layer protocol is GigabitEthernet or FDDI, OSPFv3 defaults the network type to broadcast.
- P2P: If the link layer protocol is PPP, LAPB, OSPFv3 defaults the network type to P2P.

You can change network types and configure OSPFv3 features to flexibly build networks without changing link layer protocols.

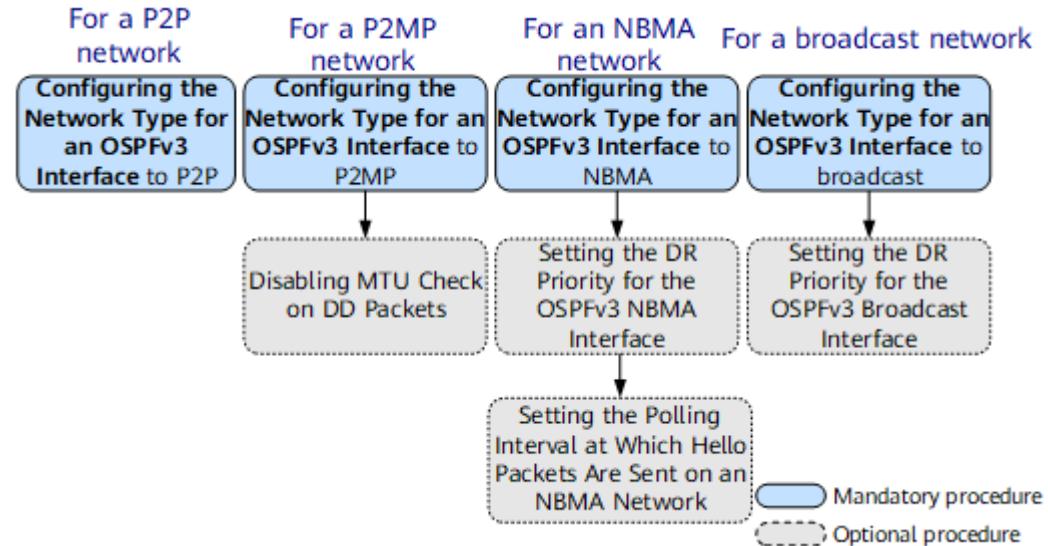

#### Pre-configuration Tasks

Before configuring OSPFv3 attributes on different types of networks, complete the following tasks:

- Configure a link layer protocol.
- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPFv3 functions](#).

## Configuration Procedures

Figure 1-184 Flowchart for configuring OSPFv3 attributes on different types of networks

## Configuring the Network Type for an Interface

OSPFv3 classifies networks into broadcast, P2P, P2MP, and NBMA networks based on link layer protocols. By configuring network types for interfaces, you can change the network types of interfaces.

### Context

By default, the network type of an interface is determined by the physical interface. The network type of Ethernet interfaces is **broadcast**.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

#### Step 3 Run **ospfv3 network-type { broadcast | nbma | p2mp [ non-broadcast ] | p2p } [ instance instance-id ]**

The network type is configured for the OSPFv3 interface.

After a new network type is configured for an interface, the network type of the original interface is replaced.

#### NOTE

The network types of two OSPFv3 interfaces at both ends of a link must be identical. Otherwise, the OSPFv3 neighbor relationship cannot be established.

#### Step 4 Run commit

The configuration is committed.

----End

### (Optional) Setting the DR Priority for the OSPFv3 Broadcast or NBMA Interface

You can specify the Designated Router (DR) priority for each interface on a broadcast or a non-broadcast multiple access (NBMA) network for DR/Backup Designated Router (BDR) election on the network.

### Context

When configuring broadcast networks or NBMA networks, you can specify the DR priority for each interface for DR/BDR election on the network. The greater the value, the higher the priority.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run **interface** *interface-type interface-number*

The interface view is displayed.

#### Step 3 Run **ospfv3 dr-priority** *priority*[ **instance** *instance-id* ]

The DR priority of the OSPFv3 interface is set.

#### Step 4 (Optional) Run **ospfv3 timer wait** *interval* [ **instance** *instance-id* ]

The wait timer on an OSPFv3 interface is set.

If no Backup Seen event is received within the *interval*, the designated router (DR) election starts. Setting a proper value for the wait timer can slow down changes of the DR and the backup designated router (BDR) on the network, reducing network flapping. When setting the wait timer, note the following points:

- The wait timer takes effect only on broadcast and NBMA interfaces.
- The value of the wait timer cannot be greater than the value of the dead timer.

#### Step 5 Run commit

The configuration is committed.

----End

### Follow-up Procedure

#### NOTICE

Changing the priority leads to a DR/BDR re-election and interrupts the OSPFv3 adjacency between routers. Therefore, changing the priority is not recommended.

Reconfiguring the DR priority for an interface does not change the DR or BDR on the network. To reelect a DR or BDR, perform either of the following operations.

- Restart the OSPFv3 processes on all the routers.
- Run the **shutdown** and then **undo shutdown** commands on the interfaces where neighbor relationships are established.

## (Optional) Setting the Polling Interval at Which Hello Packets Are Sent on an NBMA Network

On an NBMA network, a device sends Hello packets to a neighbor that is Down at a polling interval.

### Context

Perform the following steps on the router running OSPFv3.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The OSPFv3 interface view is displayed.

#### Step 3 Run **ospfv3 timer poll interval [ instance instance-id ]**

The polling interval at which Hello packets are sent is set on the NBMA interface.

The parameter **poll interval** specifies the polling interval at which Hello packets are sent.

#### Step 4 Run **commit**

The configuration is committed.

----End

## (Optional) Disabling MTU Check on DD Packets

After you prevent an interface from checking the Maximum Transmission Unit (MTU) field in received Database Description (DD) packets, the device can receive packets with the MTU field as 0.

### Context

Perform the following steps on the router that runs OSPFv3:

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

**Step 3 Run `ospfv3 mtu-ignore [ instance instance-id ]`**

The MTU check on DD packets is disabled.

After the command is used, the interface does not check the MTU field of received DD packets.

**Step 4 Run `commit`**

The configuration is committed.

----End

## Verifying the Configuration of OSPFv3 Attributes in Different Types of Networks

After configuring attributes of OSPFv3 interfaces on different types of networks, verify information about OSPFv3 interfaces.

### Prerequisites

OSPFv3 interface attributes on different types of networks have been configured.

### Procedure

**Step 1 Run the `display ospfv3 [ process-id ] interface [ no-peer | area area-id ] [ interface-type interface-number ]` command in any view to view information about an OSPFv3 interface.**

----End

### 1.1.5.2.5 Adjusting OSPFv3 Route Selection

By adjusting OSPFv3 route selection, you can enable OSPF to meet the requirements of complex networks.

### Usage Scenario

To meet the requirements of complex networks, you can adjust OSPFv3 route selection rule by configuring the following OSPFv3 route attributes:

- Cost on the OSPFv3 interface
- Load balancing among equal-cost routes

### Pre-configuration Tasks

Before adjusting OSPFv3 route selection, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPFv3 functions](#).

### Setting the Link Cost on an OSPFv3 Interface

OSPFv3 can automatically calculate the link cost for an interface based on the interface bandwidth. You can also set the link cost for the interface.

## Context

You can control the route cost by setting different link costs for OSPFv3 interfaces.

Perform the following steps on the router that runs OSPFv3:

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 3 Run **ospfv3 cost value [ instance instanceId ]**

The link cost is set on the OSPFv3 interface.

If you do not set the cost of an OSPFv3 interface using the **ospfv3 cost cost** command, OSPFv3 automatically calculates the cost for the interface based on the interface bandwidth. The calculation formula is as follows: Cost of the interface = Bandwidth reference value/Interface bandwidth. The integer of the calculated result is the cost of the interface. If the calculated result is smaller than 1, the cost value is 1. Changing the bandwidth reference value can change the cost of an interface.

Perform the following steps to change the bandwidth reference value:

#### 1. Run **system-view**

The system view is displayed.

#### 2. Run **ospfv3 [ process-id ]**

OSPFv3 is enabled, and the OSPFv3 view is displayed.

#### 3. Run **bandwidth-reference value**

The bandwidth reference value is set.

#### 4. Run **commit**

The configuration is committed.

### Step 4 Run **commit**

The configuration is committed.

----End

## Setting the Maximum Number of Equal-Cost Routes

Routes of the same routing protocol with the same destination and cost are called equal-cost routes, and traffic can be load-balanced among these routes.

## Context

Perform the following steps on the router that runs OSPFv3:

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **maximum load-balancing number**

The maximum number of equal-cost routes is set.

If the number of equal-cost routes is greater than *number* specified in the **maximum load-balancing** command, routes are selected for load balancing based on the following criteria:

1. Route priority: Routes with smaller priority values are selected for load balancing. For details about route priority configuration, see [Step 4](#).
2. Interface index: If routes have the same priority, those with greater interface index values are selected for load balancing.
3. Next hop IP address: If routes have the same priority and interface index, those with larger IP addresses are selected for load balancing.

### Step 4 (Optional) Run **nexthop neighbor-id { interface-name | interfaceType interfaceNum } weight value**

The preference for equal-cost routes is set.

OSPFv3 selects a next hop from these equal-cost routes according to the weight. The smaller the weight is, the higher the route preference is.

### Step 5 Run **commit**

The configuration is committed.

----End

## Setting the convergence priority for OSPFv3 routes

You can adjust and optimize route selection by setting the convergence priority for OSPFv3 routes.

## Context

You can set a convergence priority for the OSPFv3 routes matching the specified IPv6 prefix list. The configuration takes effect on the public network only.

OSPFv3 route calculation, LSA flooding, and LSDB synchronization can be implemented according to the configured priority. Therefore, route convergence can be controlled.

When an LSA meets multiple priorities, the highest priority takes effect.

OSPFv3 calculates LSAs in the sequence of intra-area routes, inter-area routes, and AS external routes. This command enables OSPFv3 to calculate the three types of routes separately according to the specified route calculation priorities. The convergence priority sequence is as follows: critical > high > medium > low. To

speed up the processing of LSAs with the higher priority, during LSA flooding, the LSAs need to be placed into the corresponding critical, high, medium, and low queues according to priorities.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ip ipv6-prefix *ipv6-prefix-name* [ index *index-number* ] matchMode *ipv6-address masklen* [ match-network ] [ greater-equal *greater-equal-value* ] [ less-equal *less-equal-value* ]**

An IPv6 prefix list is configured.

### Step 3 Run **ospfv3 [ *process-id* ]**

The OSPFv3 view is displayed.

### Step 4 Run **prefix-priority { critical | high | medium | very-low } ipv6-prefix *ipv6-prefix-name***

The convergence priority for OSPFv3 routes is set.

### Step 5 Run **commit**

The configuration is committed.

----End

## Configuring an OSPFv3 Interface to Automatically Adjust the Link Cost

Configuring an OSPFv3 interface to automatically adjust the link cost based on link quality facilitates route selection control and improves network reliability.

## Context

A bit error refers to the deviation between a bit that is sent and the bit that is received. The bit error rate (BER) refers to the number of bit errors divided by the total number of bits transferred during a studied time interval. During data transmission, a high BER will degrade or even interrupt services in extreme cases.

To prevent this problem, configure OSPFv3 interfaces to automatically adjust link costs based on link quality so that unreliable links are not used by the optimal routes.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface *interface-type* *interface-number***

The interface view is displayed.

### Step 3 Run **ipv6 enable**

IPv6 is enabled on the interface.

**Step 4** Run **ospfv3 process-id area area-id [ instance instance-id ]**

OSPFv3 is enabled on the interface.

**Step 5** Run **ospfv3 link-quality low incr-cost { cost | max-reachable } [ instance instance-id ]**

The OSPFv3 interface is enabled to automatically adjust the link cost based on link quality.

 **NOTE**

The *cost* parameter specifies the link cost adjustment value. After this parameter is specified:

- If the link quality changes from good to low, the link cost equals the original link cost plus the adjustment value. The maximum link cost allowed is 65535.
- If the link quality changes from low to good, the original link cost applies.

**Step 6** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration of OSPFv3 Route Selection

After setting OSPF route attributes, verify information about OSPFv3 interfaces and the routing table.

## Prerequisites

OSPFv3 route attributes have been configured.

## Procedure

- Run the **display ospfv3 [ process-id ] interface [ no-peer | area area-id ] [ interface-type interface-number ]** command in any view to view information about an OSPFv3 interface.
- Run the **display ospfv3 [ process-id ] routing** command in any view to view information about an OSPFv3 routing table.
- Run the **display ospfv3 [ process-id ] ecmp-group** command in any view to view information about OSPFv3 ECMP groups.

----End

### 1.1.5.2.6 Controlling OSPFv3 Routing Information

This section describes how to control OSPFv3 routing information.

## Usage Scenario

Through the configuration in this section, you can control the advertising and receiving of OSPFv3 routing information and configure OSPFv3 to import external routes.

You can control the following types of routes:

- Routes outside the local OSPFv3 area

This function can be configured on any router that runs OSPFv3. For example, you can enable the router to filter received routes and set the maximum number of equal-cost routes.

- Routes inside the local OSPFv3 area

This function can be configured only on ABRs. For example, when an ABR has multiple routes to a destination in the local area, you can configure the ABR to summarize the routes and send only a summary LSA to the backbone area.

## Pre-configuration Tasks

Before controlling OSPFv3 routing information, complete the following tasks:

- Enable IPv6.
- [Configure basic OSPFv3 functions](#).

## Configuring OSPFv3 to Import External Routes

Importing the routes discovered by other routing protocols can enrich OSPFv3 routing information.

## Context

Because OSPFv3 is a link-state routing protocol and cannot filter LSAs to be advertised directly, it can only filter routes when importing them. As such, only the routes that match the filtering conditions can be converted into LSAs and advertised.

### NOTICE

OSPFv3 and other dynamic routing protocols such as IS-IS and BGP often import routes from each other. If no routing policy is configured or a routing policy is incorrectly configured on a device where IS-IS, OSPFv3, and BGP import routes from each other, a Layer 3 routing loop may occur due to a route selection result change. As a result, services are compromised. For details about the cause of the loop, see [Routing Loop Detection for Routes Imported to OSPFv3](#).

## Procedure

### Step 1 Run `system-view`

The system view is displayed.

### Step 2 Run `ospfv3 [ process-id ]`

The OSPFv3 view is displayed.

### Step 3 Run `default { cost costvalue | tag tagvalue | type typevalue } *`

The default cost is set for imported routes.

**Step 4** Run **import-route { bgp [ permit-ibgp ] | direct | static | unr } [ { cost *cost* | inherit-cost } | tag *tag* | type *type* | { route-policy *route-policy-name* | route-filter *route-filter-name* } ] \***

The device is configured to import external routes.

 **NOTE**

The **import-route** command cannot be used to import the default route from another AS.

**Step 5** (Optional) Run **import-route limit *limit-number* [ threshold-alarm { upper-limit *upper-limit-value* | lower-limit *lower-limit-value* } ] \***

A limit is configured on the number of imported external routes to be advertised by OSPFv3.

If OSPFv3 imports a large number of external routes and advertises them to a device with a small routing table capacity, the device may restart unexpectedly. To prevent this problem, configure a limit on the number of imported external routes to be advertised by OSPFv3.

Ensure that *upper-limit-value* is greater than or equal to *lower-limit-value*.

**Step 6** Run **commit**

The configuration is committed.

----End

## Configuring OSPFv3 to Advertise Default Routes to OSPFv3 Areas

You can configure OSPFv3 to advertise default routes to OSPFv3 areas. Only the routes that meet the conditions can be converted into LSAs and advertised.

### Context

Perform the following steps on the router that runs OSPFv3:

### Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

**Step 3** Run **default-route-advertise [ always | cost *cost* | type *type* | tag *tag* | { route-policy *route-policy-name* | route-filter *route-filter-name* } | permit-preference-less-than *preference-value* ] \***

The device is configured to advertise default routes to OSPFv3 areas.

 **NOTE**

To prevent loops, you are advised to specify **permit-preference-less-than** to prevent low-priority active default routes from being imported. This parameter is used only when **always** is not specified.

#### Step 4 Run commit

The configuration is committed.

----End

### Configuring OSPFv3 to Filter Received Routes

After receiving Link State Advertisements (LSAs), OSPFv3 determines whether to add the calculated routes to the local routing table based on a filtering policy.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run ospfv3 [ process-id ]

The OSPFv3 view is displayed.

#### Step 3 Run any of the following commands as required:

- Configure a basic ACL:

- a. Run **quit**

Return to the system view.

- b. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**

The ACL view is displayed.

- c. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ] \***

A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:

If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

- d. Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

- e. Run **filter-policy { acl6-number| acl6-name acl6-name } import**

An import policy that is based on the ACL is configured to filter received routes.

- Based on an IPv6 prefix list:

Run **filter-policy ipv6-prefix ipv6-prefix-name import**

An import policy that is based on an IPv6 prefix list is configured to filter received routes.

- Based on a route-policy:

Run **filter-policy route-policy route-policy-name import**

An import policy that is based on a route-policy is configured to filter received routes.

- Based on a route-filter:

Run **filter-policy route-filter route-filter-name import**

An import policy that is based on a route-filter is configured to filter received routes.

The **filter-policy import** command is used to filter the routes calculated by OSPFv3. Only the routes that match the filtering rules are added to the routing table and can be advertised. Routes that do not match the filtering rules can be added to the OSPFv3 routing table but not to the routing information base (RIB) and cannot be advertised. Therefore, the LSDB is not affected regardless of whether the received routes match the filtering rules.

#### Step 4 Run commit

The configuration is committed.

----End

### Configuring OSPFv3 to Filter the Routes to Be Advertised

After filtering conditions are set for imported routes, only the routes that pass the filtering can be advertised.

## Context

When OSPFv3 receives LSAs, it can filter the received routes based on a filtering policy before advertising them to neighbors.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 (Optional) Run **default-route-advertise [ [ always | permit-calculate-other | cost cost | type type | tag tag | distribute-delay delay | route-policy route-policy-name | route-filter route-filter-name } | permit-preference-less-than preference-val ] ] \***

The device is configured to advertise default routes to OSPFv3 areas.

To prevent loops, you are advised to specify **permit-preference-less-than** to prevent low-priority active default routes from being imported. This parameter is used only when **always** is not specified.

### Step 4 Run any of the following commands as required:

- Configure a basic ACL:

#### a. Run **quit**

Return to the system view.

#### b. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**

The ACL view is displayed.

#### c. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ] \***

A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.

- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:
  - If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.  
Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.  
Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.
- d. Run **ospfv3 [ process-id ]**  
The OSPFv3 view is displayed.
- e. Run **filter-policy { acl-number | acl6-name acl6-name } export [ bgp | direct | static | unr | { isis | ospfv3 | ripng } [ process-id ] ]**  
An export policy is configured to filter the routes that are imported using the **import-route** command and are to be advertised. Only the matched routes can be advertised.
- Based on an IPv6 prefix list:  
Run **filter-policy ipv6-prefix ipv6-prefix-name export [ bgp | direct | static | unr | { isis | ospfv3 | ripng } [ process-id ] ]**  
An export policy is configured to filter the routes that are imported using the **import-route** command and are to be advertised. Only the matched routes can be advertised.

You can specify the protocol type or *process-id* to match the routes of a specified protocol or process. If no protocol type or *process-id* is specified, OSPFv3 filters all imported routes.

#### Step 5 Run commit

The configuration is committed.

----End

### Configuring OSPFv3 to Filter LSAs in an Area

Filtering LSAs in an area can prevent unnecessary LSA transmission. This reduces the size of the LSDB on the neighboring device and speeds up network convergence.

### Context

After filtering conditions are set for the incoming or outgoing Type 3 LSAs (Inter-Area-Prefix LSAs) in an area, only the Type 3 LSAs that meet the filtering conditions can be received or advertised.

This function is applicable only to the ABR.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **area area-id**

The OSPFv3 area view is displayed.

### Step 4 Filter incoming or outgoing Type 3 LSAs in the area.

- Filter incoming Type 3 LSAs in the area. Run any of the following commands as required:

- Configure a basic ACL:

- i. Run **quit**

Return to the OSPFv3 view.

- ii. Run **quit**

Return to the system view.

- iii. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**

The ACL view is displayed.

- iv. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ] \***

A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:  
If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

v. Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

vi. Run **area area-id**

The OSPFv3 area view is displayed.

vii. Run **filter { acl6-number | acl6-name acl6-name } import**

Incoming Type 3 LSAs in the area are filtered based on the ACL.

- Based on an IPv6 prefix list:

Run **filter ipv6-prefix ipv6-prefix-name import**

Incoming Type 3 LSAs in the area are filtered based on an IP prefix list.

- Based on a route-policy:

Run **filter route-policy route-policy-name import**

Incoming Type 3 LSAs in the area are filtered based on a route-policy.

- Based on a route-filter:

Run **filter route-filter route-filter-name import**

Incoming Type 3 LSAs in the area are filtered based on a route-filter.

- Filter outgoing Type 3 LSAs in the area. Run any of the following commands as required:

- Configure a basic ACL:

i. Run **quit**

Return to the OSPFv3 view.

ii. Run **quit**

Return to the system view.

iii. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**

The ACL view is displayed.

iv. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ] \***

A rule is configured for the ACL. When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
  - If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
  - If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
  - If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
  - Routes can be filtered using a blacklist or whitelist:  
If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.  
Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.  
Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.
- v. Run **ospfv3 [ process-id ]**  
The OSPFv3 view is displayed.
  - vi. Run **area area-id**  
The OSPFv3 area view is displayed.
  - vii. Run **filter { acl6-number | acl6-name acl6-name } export**  
Outgoing Type 3 LSAs in the area are filtered based on the ACL.
    - Based on an IPv6 prefix list:  
Run **filter ipv6-prefix ipv6-prefix-name export**  
Outgoing Type 3 LSAs in the area are filtered based on an IP prefix list.
    - Based on a route-policy:  
Run **filter route-policy route-policy-name export**  
Outgoing Type 3 LSAs in the area are filtered based on a route-policy.
    - Based on a route-filter:  
Run **filter route-filter route-filter-name export**  
Outgoing Type 3 LSAs in the area are filtered based on a route-filter.

#### Step 5 Run commit

The configuration is committed.

----End

#### (Optional) Configuring OSPFv3 to Discard Specified LSAs

You can configure a device to discard specified LSAs in an OSPFv3 process.

## Context

OSPFv3 can be configured to discard specified LSAs in the following scenarios:

- When devices on the entire network restart repeatedly due to abnormal LSAs and you have located the LSA that causes protocol restarts, you can configure this function as a last resort to prevent the device from restarting continuously. However, if this function is incorrectly configured, routing loops may occur.
- If an LSA is identified as an attack packet, which is not supposed to appear in the local area, and has caused serious problems, such as device restarts, you can configure this function to filter out the LSA under the condition that the attack source cannot be located temporarily and that the LSA does not affect topology path computation.
- If an LSA is identified as an attack packet, which is not supposed to appear in the local area, and it affects topology path computation and has caused serious problems, such as network-wide device restarts, you can configure this function on each device to discard the LSA to prevent it from participating in network-wide calculation.

### NOTE

To filter out the LSA that affects topology path computation, you must ensure that it is removed from all the LSDBs on the entire network. Otherwise, routing loops may occur.

- If an LSA is identified as an unreachable residual LSA and the device that advertised the LSA becomes permanently unreachable, you can configure this function to filter out the LSA upon reception under the condition that the LSA does not affect topology path computation.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **ignore-receive-lsa advertise-router adv-rtr-id [ lsa-type type-value [ area { area-id | area-idipv4 } ] | link-state-id ls-id ] \***

The device is configured to discard LSAs of a specified type.

 NOTE

- You are not advised to run this command to filter out the LSAs that exist on the network as running this command may filter out normal LSAs.
- This command cannot be used to defend against attacks as it goes against protocol processing rules and affects services. Therefore, exercise caution when running this command.
- As an attack LSA can have any key, it is difficult to defend against the LSA using this command. Therefore, you are advised to directly isolate the attack source.
- If this command is incorrectly configured, services cannot be restored even if the **undo ignore-receive-lsa advertise-router adv-rtr-id [ lsa-type type-value [ area { area-id | area-id|ipv4 } ] | link-state-id ls-id ] \* command** is run. In this case, you may need to reset the process or neighbor to restore services.
- If the fault is caused by a bug, you are advised to run this command temporarily. After the patch is installed, run the **undo ignore-receive-lsa advertise-router adv-rtr-id [ lsa-type type-value [ area { area-id | area-id|ipv4 } ] | link-state-id ls-id ] \* command** immediately and check whether services are affected. If services are affected, re-establish all neighbor relationships to restore services.

**Step 4 Run commit**

The configuration is committed.

----End

## Configuring OSPFv3 Route Summarization

Routes with the same IPv6 prefix can be summarized into one route. On a large-scale OSPFv3 network, route lookup may slow down because of the large size of the routing table. To reduce the routing table size and simplify management, configure route summarization. With route summarization, if a link connected to a device within an IPv6 address range that has been summarized alternates between Up and Down, the link status change is not advertised to the devices beyond the IPv6 address range. This prevents route flapping and improves network stability.

## Context

OSPFv3 route summarization is classified as follows:

- Route summarization on an ABR, which is configured using the **abr-summary** command. When an ABR transmits routing information to other areas, it generates Type 3 LSAs for each network segment. If contiguous segments exist in this area, run the **abr-summary** command to summarize these segments into one segment so that the ABR sends only one summarized LSA.
- Route summarization on an ASBR, which is configured using the **asbr-summary** command. The ASBR summarizes routes of imported Type 5 LSAs within the summarized address range. If a large number of routes with the same IPv6 prefix are imported, run the **asbr-summary** command to summarize them into one route.

## Procedure

- Configure route summarization on an ABR.
  - a. Run **system-view**

- The system view is displayed.
- b. Run **ospfv3** [ *process-id* ]
- The OSPFv3 view is displayed.
- c. Run **area** *area-id*
- The OSPFv3 area view is displayed.
- d. Run **abr-summary** *ipv6-address prefix-length* [ **not-advertise** | **cost** *cost-value* | **hold-max-cost** *interval* ] \* The ABR is configured to summarize intra-area routes.
- The **not-advertise** parameter indicates that the routes in this network segment are not advertised.
  - The **cost** *cost-value* parameter specifies a cost for the summary route.
  - The **hold-max-cost** *interval* parameter specifies the period during which the maximum cost is advertised in the summary route.
- e. Run **commit**
- The configuration is committed.
- Configure route summarization on an ASBR.
- a. Run **system-view**
- The system view is displayed.
- b. Run **ospfv3** [ *process-id* ]
- The OSPFv3 view is displayed.
- c. Run **asbr-summary** *ipv6-address prefix-length* [ **not-advertise** | **tag** *tag-value* | **cost** *cost-value* | **distribute-delay** *interval* ] \*
- The ASBR is configured to summarize the routes imported by OSPFv3.
- The **cost** *cost-value* parameter specifies a cost for the summary route.
  - The **tag** *tag-value* parameter specifies a tag value used to control summary route advertisement.
  - The **not-advertise** parameter indicates that the summary IPv6 routes that match the specified IPv6 prefix or prefix length are not advertised.
  - The **distribute-delay** *interval* parameter sets a delay for advertising a summary route. This ensures that the summary route advertised each time contains more valid routes and prevents network flapping caused by incorrect routing information.
- d. Run **commit**
- The configuration is committed.

----End

## Verifying the Configuration of OSPFv3 Routing Information Control

After controlling OSPFv3 routing information, verify the OSPFv3 LSDB.

### Prerequisites

OSPFv3 routing information has been controlled.

### Procedure

- Run the **display ospfv3 [ process-id ] lsdb** command to view the OSPFv3 LSDB.
- Run either of the following commands to check OSPFv3 route information:
  - Run the **display ospfv3 [ process-id ] abr-summary-list [ ipv6-address prefix-length ]** command to check information about the summarized routes on an ABR.
  - Run the **display ospfv3 [ process-id ] asbr-summary [ ipv6-address prefix-length ] [ verbose ]** command to check information about the summarized routes on an ASBR.

----End

### 1.1.5.2.7 Configuring OSPFv3 Delay Advertisement

With OSPFv3 delay advertisement, intra-domain link delay information can be collected and flooded.

### Usage Scenario

Traditional path computation algorithms compute the optimal path to a destination address based on costs. However, the path computed in this way may not have the minimum delay. For services that have stringent requirements on delay, path computation can be performed based on the delay rather than on the cost to ensure that service traffic is transmitted along the path with the minimum delay. After OSPFv3 delay advertisement is configured, OSPFv3 collects and floods intra-domain link delay information and reports the information to the controller through BGP-LS. The controller then computes paths on the P2P network based on delay constraints.

### Pre-configuration Tasks

Before configuring delay advertisement, configure TWAMP Light to detect delay information. The configuration is as follows:

- Configure the TWAMP Light controller function on the local end.
  - a. Configure the TWAMP Light client function, and create a test session.
    - i. Run **system-view**  
The system view is displayed.
    - ii. Run **nqa twamp-light**  
The TWAMP Light view is displayed.
    - iii. Run **client**

- The TWAMP Light client function is enabled, and the TWAMP Light client view is displayed.
- iv. Run **test-session session-id sender-ipv6 sender-address-v6 reflector-ipv6 reflector-address-v6 sender-port sender-port reflector-port reflector-port [ dscp dscp-value | padding padding-length | padding-type padding-type | description description ] \***  
A test session is created on the initiator.
  - v. Run **quit**  
Return to the TWAMP Light view.
- b. Configure the TWAMP Light Sender and start the TWAMP Light performance test.
    - i. Run **sender**  
The TWAMP Light Sender function is enabled, and the TWAMP Light Sender view is displayed.
    - ii. Run **test start-continual test-session session-id [ period { 10 | 100 | 1000 | 30000 } ] [ time-out time-out ]**  
Continual measurement is started.
    - iii. Run **commit**  
The configuration is committed.
- Configure the TWAMP Light Responder on the peer end.
    - a. Run **system-view**  
The system view is displayed.
    - b. Run **nqa twamp-light**  
The TWAMP Light view is displayed.
    - c. Run **responder**  
The TWAMP Light Responder function is enabled, and the TWAMP Light Responder view is displayed.
    - d. Run **test-session session-id local-ipv6 local-ipv6-address remote-ipv6 remote-ipv6-address local-port local-port remote-port remote-port interface { interface-type interface-number | interface-name } [ anti-loop-on ] [ description description ]**  
A test session is created on the reflector.
    - e. Run **commit**  
The configuration is committed.

For details about how to configure TWAMP Light, see TWAMP Light.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

An OSPFv3 process is created, and the OSPFv3 view is displayed.

*process-id* specifies an OSPFv3 process. If *process-id* is not specified, the default process ID 1 is used.

**Step 3** Run **router-id** *router-id*

A router ID is configured.

A router ID uniquely identifies an OSPFv3 process in an AS. If no router ID is configured, the OSPFv3 process cannot run.

**Step 4** Run **metric-delay** [ **average** | **variation** ] **advertisement enable**

OSPFv3 delay advertisement is configured.

**Step 5** (Optional) Run **metric-delay normalize interval** *interval-value* [ **offset** *offset-value* ]

The link delay tolerance in the OSPFv3 process is configured.

For the delay-based path computation algorithm, the delay differences of links are different, and the differences may be small. However, even if the delay differences are small, only one optimal path can be generated according to the existing SPF algorithm, and load balancing cannot be implemented within a certain delay tolerance range. As a result, link resources on the network cannot be fully utilized. To resolve this problem to the greatest extent, normalization processing may be performed on the link delays with a small difference or a difference within an acceptable range so that load balancing can be implemented and link resources on the network can be fully utilized.

**Step 6** (Optional) Run **metric-delay suppress timer** *timer-value* **percent-threshold** *percent-value* **absolute-threshold** *absolute-value*

Delay advertisement suppression is configured.

If delay variation occurs frequently, the delay-based route calculation changes frequently. As a result, routing information is flooded and reported repeatedly. In this case, you can configure this function to suppress delay advertisement.

**Step 7** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After the configuration is complete, run the **display ospfv3 traffic-eng** command to check the delay information advertised by OSPFv3.

### 1.1.5.2.8 Disabling DN Bit Setting in OSPFv3 LSAs

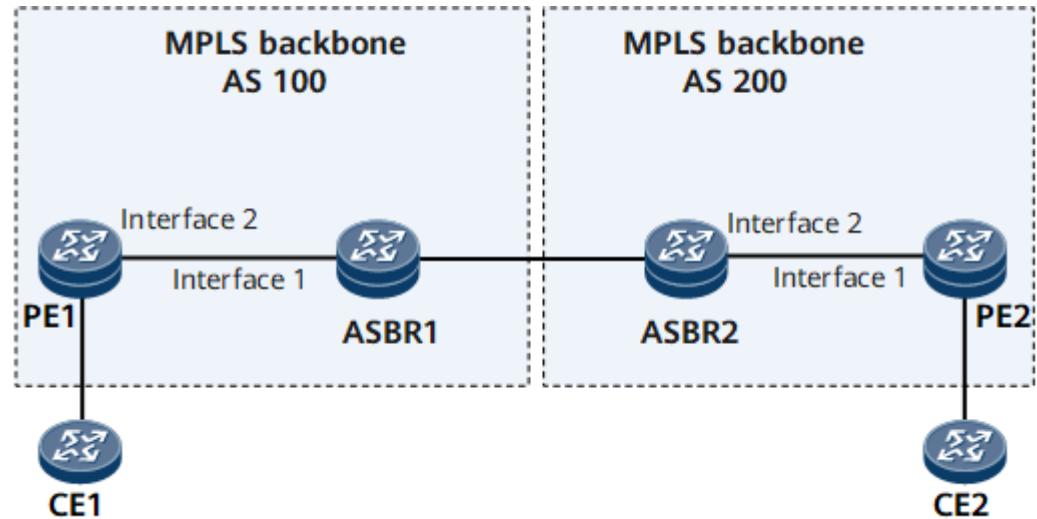

In a VPN Option A scenario, disabling DN bit setting in OSPFv3 LSAs allows PEs in different ASs to communicate with each other.

## Usage Scenario

[Figure 1-185](#) shows a VPN Option A scenario where an OSPFv3 neighbor relationship is established between ASBR1 and ASBR2. Each of the ASBRs imports

BGP routes from the connected PE to the OSPFv3 process, generates LSAs, and advertises the LSAs to the peer ASBR. The ASBRs, however, cannot use the received LSAs to generate OSPFv3 routes. This is because LSAs with the DN bit set cannot be used for route calculation, as defined in a standard protocol. Consequently, no OSPFv3 routes will be imported into BGP processes on the ASBRs, and no BGP routes will be advertised to the connected PEs, causing traffic loss. To prevent this issue, you can disable DN bit setting in OSPFv3 LSAs.

**Figure 1-185** OSPFv3 application in the VPN Option A scenario

## Pre-configuration Tasks

Configure a VPN instance before disabling DN bit setting in OSPFv3 LSAs.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ] [ vpn-instance vpnname ]**

An OSPFv3 process bound to the existing VPN instance is started, and the view of the OSPFv3 process is displayed.

An OSPFv3 process can be bound to only one VPN instance. If an OSPFv3 process is not bound to any VPN instance before being started, this process is a public network process. The public network OSPFv3 process cannot be bound to a VPN instance.

#### NOTE

Deleting a VPN instance or disabling the IPv6 address family in the VPN instance will delete all the associated OSPFv3 processes.

### Step 3 Run **router-id router-id**

A router ID is configured.

A router ID uniquely identifies an OSPFv3 process in an AS. If no router ID is configured, the OSPFv3 process cannot run.

**Step 4** Run **import-route bgp [ cost cost | { route-policy route-policy-name | route-filter route-filter-name } | tag tag | type type ]\***

The device is configured to import BGP routes into OSPFv3.

**Step 5** Run **dn-bit-set disable { summary | ase | nssa }**

DN bit setting in OSPFv3 LSAs is disabled.

**Step 6** Run **commit**

The configuration is committed.

----End

### 1.1.5.2.9 Configuring OSPFv3 Neighbor Relationship Flapping Suppression

OSPFv3 neighbor relationship flapping suppression works by delaying OSPFv3 neighbor relationship reestablishment or setting the link cost to the maximum value.

#### Usage Scenario

If an interface carrying OSPFv3 services alternates between up and down, OSPFv3 neighbor relationship flapping occurs on the interface. During the flapping, OSPFv3 frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, OSPFv3 services, and other OSPFv3-dependent services. OSPFv3 neighbor relationship flapping suppression can address this problem by delaying OSPFv3 neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

#### Pre-configuration Tasks

Before configuring OSPFv3 neighbor relationship flapping suppression, complete the following tasks:

- Configure an IP address for each interface to ensure that neighboring devices are reachable at the network layer.
- [Configure basic OSPFv3 functions](#).

#### Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** (Optional) Disable OSPFv3 neighbor relationship flapping suppression globally.

- Run the **ospfv3 [ process-id ]** command to enter the OSPFv3 view.
- Run the **suppress-flapping peer disable** command to disable OSPFv3 neighbor relationship flapping suppression.

To disable the function globally, perform this step.

**Step 3** Run **interface interface-type interface-number**

The interface view is displayed.

**Step 4** (Optional) Run **ospfv3 suppress-flapping peer disable**

OSPFv3 neighbor relationship flapping suppression is disabled on the interface.

To disable the function on one of the interfaces, perform this step.

**Step 5** Configure an OSPFv3 neighbor relationship flapping suppression mode, which can be Hold-down or Hold-max-cost mode.

- Hold-down mode:

Run the **ospfv3 suppress-flapping peer hold-down interval [ instance instance-id ]** command to configure the Hold-down mode and set its duration.

If flooding and topology changes frequently occur during OSPFv3 neighbor relationship establishment, you can configure the Hold-down mode to prevent OSPFv3 neighbor relationship reestablishment within a period of time. This prevents frequent LSDB synchronization and a large number of packets from being exchanged.

- Hold-max-cost mode:

If user service traffic is frequently switched, you can configure OSPFv3 neighbor relationship flapping suppression to work in Hold-max-cost mode. In this mode, the link cost is set to the maximum value (Max-cost) within a period of time, preventing user service traffic from passing through flapping links.

- a. (Optional) Set the maximum cost for OSPFv3 links. If the value needs to be modified, perform this step.

- i. Run **quit**

Return to the system view.

- ii. Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

- iii. Run **maximum-link-cost cost**

The maximum cost of OSPFv3 is set.

- iv. Run **quit**

Return to the system view.

- v. Run **interface interface-type interface-number**

The interface view is displayed.

- b. (Optional) Run **ospfv3 suppress-flapping peer hold-max-cost disable [ instance instance-id ]**

The Hold-max-cost neighbor relationship flapping mode is disabled.

To disable the Hold-max-cost neighbor relationship flapping suppression mode, perform this step.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

**Step 6** (Optional) Run **ospfv3 suppress-flapping peer { detecting-interval *detecting-interval* | threshold *threshold* | resume-interval *resume-interval* }\* [ instance *instance-id* ]**

Detection parameters are configured for OSPFv3 neighbor relationship flapping suppression.

Each OSPFv3 interface on which OSPFv3 neighbor relationship flapping suppression is enabled starts a flapping counter. If the interval between two successive neighbor status changes from Full to a non-Full state is shorter than *detecting-interval*, a valid flapping\_event is recorded, and the flapping\_count is incremented by 1.

When the flapping\_count reaches or exceeds *threshold*, flapping suppression takes effect.

If the interval between two successive neighbor status changes from Full to a non-Full state is longer than *resume-interval*, the flapping\_count is reset.

 **NOTE**

The value of *resume-interval* must be greater than that of *detecting-interval*.

You can configure detection parameters for OSPFv3 neighbor relationship flapping suppression on specific interfaces according to network conditions. However, using the default values of these parameters is recommended.

**Step 7** Run **quit**

Return to the system view.

**Step 8** Run **commit**

The configuration is committed.

**Step 9** Run **quit**

Return to the user view.

**Step 10** (Optional) Run **reset ospfv3 *process-id* suppress-flapping peer [ interface-type *interface-number* ] [ notify-peer ]**

The OSPFv3 interface is configured to exit neighbor relationship flapping suppression.

To exit neighbor relationship flapping suppression in advance after the fault that causes OSPFv3 neighbor relationship flapping is rectified, perform this step.

 NOTE

Interfaces exit flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding OSPFv3 process is reset.
- An OSPFv3 neighbor relationship is reset using the **reset ospfv3 peer** command.
- OSPFv3 neighbor relationship flapping suppression is disabled globally using the **suppress-flapping peer disable** command in the OSPFv3 view.
- The **reset ospfv3 suppress-flapping peer** command is run to exit flapping suppression.

----End

## Verifying the Configuration

Run the **display ospfv3 [ process-id ] interface [ no-peer | area area-id ] [ interface-type interface-number ]** command to check the status of OSPFv3 neighbor relationship flapping suppression.

### 1.1.5.2.10 Configuring Routing Loop Detection for Routes Imported to OSPFv3

Routing loop detection for routes imported into OSPFv3 enables a device to check whether routes advertised by the device are imported back. If routes advertised by the device are imported back, the device advertises a large link cost for the routes to prevent routing loops.

## Usage Scenario

Routing loops may occur when an OSPFv3 process imports routes. If routing loop detection is enabled for routes imported to OSPFv3 on a device and this device detects that it imports a route advertised by itself, it sends this route with a large link cost to other devices. After receiving this route, these devices preferentially select other paths, thereby preventing routing loops.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 (Optional) Run **clear route loop-detect ospfv3 alarm-state**

The routing loop detection alarm state exits, and related alarms are cleared.

 NOTE

After detecting an OSPFv3 routing loop, the device reports an alarm. Because the device cannot automatically detect whether the routing loop is eliminated, you need to run this command after the routing loop is eliminated to prevent the device from advertising a large cost for imported routes and manually clear the OSPFv3 routing loop alarm. If this command is executed when the routing loop has not been eliminated, the alarm is reported again.

### Step 3 Run **route loop-detect ospfv3 enable**

Routing loop detection is enabled for routes imported to OSPFv3.

 NOTE

To reduce the impact of routing loops on services, you are advised to enable routing loop detection for routes imported to OSPFv3.

**Step 4 Run commit**

The configuration is committed.

----End

### 1.1.5.2.11 Disabling OSPFv3 Interface Flapping Suppression

OSPFv3 interface flapping suppression is globally enabled by default. If this function is not needed, you can disable it.

#### Usage Scenario

If OSPFv3 interfaces frequently alternate between up and down, the interfaces will flap, and protocol packets will be frequently exchanged, affecting OSPFv3 services and other services relying on OSPFv3. Interface flapping suppression can address this issue. This function allows a device to delay interface state changes to up. If this function is not needed, you can disable it.

#### Pre-configuration Tasks

Before configuring OSPFv3 interface flapping suppression, [configure basic OSPFv3 functions](#).

#### Procedure

**Step 1 Run system-view**

The system view is displayed.

**Step 2 Run ospfv3 suppress-flapping interface disable**

OSPFv3 interface flapping suppression is disabled.

**Step 3 Run commit**

The configuration is committed.

----End

#### Checking the Configuration

Run the **display current-configuration configuration ospfv3** command to check the status of OSPFv3 interface flapping suppression.

### 1.1.5.2.12 Configuring OSPFv3 Flush Source Tracing

OSPFv3 flush source tracing helps improve fault locating efficiency.

#### Usage Scenario

If network-wide OSPFv3 LSAs are deleted, flush LSAs are flooded, which adversely affects network stability. In this case, source tracing must be implemented to

locate the root cause of the fault immediately to minimize the impact. However, OSPFv3 itself does not support source tracing. A conventional solution is isolation node by node until the faulty node is located, but the solution is complex and time-consuming. To address this problem, enable OSPFv3 flush source tracing.

 NOTE

The following steps are optional, and choose them as required.

## Pre-configuration Tasks

Before configuring OSPFv3 flush source tracing, complete the following task:

- Configure an IP address for each interface to ensure that neighboring devices are reachable at the network layer.
- [Configure basic OSPFv3 functions](#).

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** (Optional) Run **ospfv3 flush-source-trace disable**

OSPFv3 flush source tracing is disabled globally.

To disable OSPFv3 flush source tracing globally, perform this step.

**Step 3** Run **interface *interface-type* *interface-number***

The interface view is displayed.

**Step 4** (Optional) Run **ospfv3 flush-source-trace block**

OSPFv3 flush source tracing is disabled on the interface.

To disable OSPFv3 flush source tracing on an interface, perform this step.

**Step 5** Run **quit**

Return to the system view.

**Step 6** Run **ospfv3 [ *process-id* ] [ **vpn-instance** *vpn-instance-name* ]**

The OSPFv3 process is started, and the OSPFv3 view is displayed.

**Step 7** Run **quit**

Return to the system view.

**Step 8** Run **ospfv3 flush-source-trace port *port-number***

A UDP port number is configured for OSPFv3 flush source tracing packets.

An OSPFv3 flush source tracing port is used to send and receive OSPFv3 flush source tracing packets and is represented by a UDP port number. If the port number used by UDP packets conflicts with that of another application, perform this step.

### Step 9 Run commit

The configuration is committed.

### Step 10 Run quit

Return to the user view.

### Step 11 Run **reset ospfv3 [ process-id ] flush-source-trace**

OSPFv3 flush source tracing is reset.

If a large number of OSPFv3 flush source tracing statistics exist on a device, you can run the **reset ospfv3 flush-source-trace** command to reset the statistics and restart source tracing. If the command is run, all dynamic source tracing statistics are deleted, and the device needs to re-negotiate the source tracing capability with neighboring devices.

----End

## Verifying the Configuration

Run the **display ospfv3 [ process-id ] [ area area-id-integer ] flush-source-trace analysis-info** command to check information about determined and suspected faulty nodes identified by OSPFv3 flush source tracing.

### 1.1.5.2.13 Configuring an OSPFv3 Hostname

Compared with router IDs, OSPFv3 hostnames are easier to memorize. Therefore, using hostnames to identify routers can facilitate network management.

## Usage Scenario

To facilitate network management, configure dynamic OSPFv3 hostnames to identify routers.

Either dynamic or static OSPFv3 hostnames can be configured. In dynamic mode, a hostname can be configured on and advertised by the local device. The mapping between the local device's router ID and hostname can then be queried on a remote router that successfully learns this dynamic hostname.

## Pre-configuration Tasks

Before configuring a hostname, complete the following tasks:

- Configure an IP address for each interface to ensure that neighboring routers can use the IP addresses to communicate with each other.
- Configure basic OSPFv3 functions.**

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **hostname host-name**

A dynamic OSPFv3 hostname is configured.

#### NOTE

If the *host-name* parameter is specified, the value of *host-name* is advertised as the dynamic hostname. If only the **hostname** command is run and *host-name* is not specified, the device name specified in the **sysname** command is advertised as the dynamic hostname.

### Step 4 Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

Run the following command to check dynamic OSPFv3 hostnames:

- **display ospfv3 [ process-id ] hostname-table**

### 1.1.5.2.14 Configuring an OSPFv3 Stub Area

A non-backbone area in the edge of an AS can be configured as a stub area so that routes from other areas on the OSPFv3 network or AS external routes are not transmitted. This reduces bandwidth and storage resource consumption on the router, routing table size, and the amount of routing information to be transmitted.

## Usage Scenario

The number of LSAs can be reduced by partitioning an AS into different areas. To reduce the number of entries in the routing table and the number of LSAs to be transmitted in a non-backbone area, configure the non-backbone area on the border of the AS as a stub area.

Configuring a stub area is optional. A stub area generally resides on the border of an AS. For example, a non-backbone area with only one ABR can be configured as a stub area. In a stub area, the number of entries in the routing table and the amount of routing information to be transmitted greatly decrease.

Note the following points when configuring a stub area:

- The backbone area (Area 0) cannot be configured as a stub area.
- If an area needs to be configured as a stub area, all the routers in this area must be configured with stub attributes using the **stub** command.
- An ASBR cannot exist in a stub area. External routes are not transmitted in the stub area.

## Pre-configuration Tasks

Before configuring a stub area, complete the following tasks:

- Configuring IP addresses for interfaces to ensure that neighboring routers are reachable at the network layer

- **Configuring Basic OSPFv3 Functions**

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

**Step 3** Run **area area-id**

The OSPFv3 area view is displayed.

**Step 4** Run **stub**

The specified area is configured as a stub area.

 **NOTE**

- All routers in a stub area must be configured with stub attributes using the **stub** command.
- Configuring or deleting stub attributes will update routing information in the area. Stub attributes can be deleted or configured again only after the routing update is complete.

**Step 5** (Optional) Run **stub no-summary**

The ABR is prevented from sending Type 3 LSAs (Summary LSAs) to the stub area.

**Step 6** (Optional) Run **stub default-route-advertise backbone-peer-ignore**

The device is configured to advertise default routes and ignore the status of the neighbors in the backbone area.

**Step 7** (Optional) Run **default-cost cost**

The cost of the default route to the stub area is set.

To ensure the reachability of AS external routes, the ABR in the stub area generates a default route and advertises the route to the other routers in the stub area.

**Step 8** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

Run the **display ospfv3 [ process-id ] lsdb** command, and you can view LSDB information, including the types of LSAs and link state IDs.

When Router is in a common area, there are AS external routes in the routing table. After the area where Router resides is configured as a stub area, AS external routes are invisible.

### 1.1.5.2.15 Configuring an OSPFv3 NSSA

By configuring a non-backbone area on the border of an autonomous system (AS) as a not-so-stubby area (NSSA), you can reduce the size of the routing table and the amount of routing information to be transmitted.

#### Usage Scenario

An excessive number of entries in a routing table wastes network resources and causes high CPU usage. To reduce the number of entries in a routing table and the amount of routing information to be transmitted, configure a non-backbone area on the border of an AS as a stub area or an NSSA. For details about how to configure an OSPFv3 stub area, see [1.1.5.2.14 Configuring an OSPFv3 Stub Area](#).

OSPFv3 stub areas cannot import external routes from outside an AS, nor can they learn the external routes imported by the other areas in the same AS. To import external routes to an area and minimize resource consumption, configure the area as an NSSA. NSSAs can import the external routes (outside an AS) and advertise them within the entire AS, without learning external routes from the other areas in the AS. This reduces the consumption of bandwidth and storage resources on the router.

NSSA attributes must be configured on all routers in an NSSA.

#### Pre-configuration Tasks

Before configuring an OSPFv3 NSSA, complete the following tasks:

- Configure an IP address for each interface to ensure that neighboring devices can communicate with each other at the network layer.
- [Configure basic OSPFv3 functions](#).

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

##### Step 3 (Optional) Run **lsa-forwarding-address { standard | zero-translate }**

The OSPFv3 forwarding address (FA) function is enabled.

##### Step 4 Run **area area-id**

The OSPFv3 area view is displayed.

##### Step 5 Run **nssa [ { default-route-advertise [ backbone-peer-ignore | cost cost-value | type type-value | tag tag-value ] \* } | no-import-route | no-summary | translator-always | translator-interval interval-value | set-n-bit | suppress-forwarding-address ] \***

The specified area is configured as an NSSA.

The usage scenarios of the **nssa** command parameters are as follows:

- To allow default Type 7 LSA generation, specify **default-route-advertise**. After this parameter is specified, a Type 7 LSA default route will be generated on an ABR, regardless of whether the route ::/0 exists in the ABR's routing table. On an ASBR, however, a Type 7 LSA default route can be generated only if the route ::/0 exists in the ASBR's routing table.
- If an ASBR also functions as an ABR, specifying **no-import-route** prevents OSPFv3 from advertising the external routes imported using the **import-route** command to the NSSA.
- To reduce the number of LSAs to be transmitted to the NSSA, specify **no-summary** on an ABR. This prevents the ABR from transmitting Summary LSAs (Type 3 LSAs) to the NSSA.

 **NOTE**

After the **nssa default-route-advertise backbone-peer-ignore no-summary** command is run, the ABR generates both the default Type 7 LSA and default Type 3 LSA as long as the backbone area contains interfaces that are up, regardless of whether neighbor relationships in Full state exist. In this case, the default Type 3 LSA preferentially takes effect.

- After **set-n-bit** is set, the DD packets sent by the router carry the N-bit of 1.
- If multiple ABRs are deployed in the NSSA, OSPFv3 automatically selects an ABR (generally the ABR with the largest router ID) as a translator to translate Type 7 LSAs into Type 5 LSAs. Each change of a translator causes LSA flooding. To prevent this issue, specify **translator-always** on an ABR to configure the ABR as a fixed translator. To allow two ABRs to participate in load balancing, configure **translator-always** on the ABRs.
- To ensure service continuity during translator switching, specify the **translator-interval** parameter. The value of *interval-value* must be greater than the flooding interval.
- To disable translated Type 5 LSAs from carrying an FA, specify the **suppress-forwarding-address** parameter.

**Step 6 Run commit**

The configuration is committed.

----End

## Verifying the Configuration

After the configuration is complete, verify it.

- Run the **display ospfv3 [ process-id ] routing [ [ ipv6-address prefix-length ] | abr-routes | asbr-routes | ase-routes | inter-routes | intra-routes | nssa-routes ] [ verbose ]** command to check the OSPFv3 routing table information.
- Run the **display ospfv3 [ process-id ] lsdb [ area area-id ] [ [ originate-router advertising-router-id | hostname hostname ] | self-originate ] { grace | inter-prefix | inter-router | intra-prefix | link | network | router | router-information | nssa } [ link-state-id ] [ age { min-value min-age-value | max-value max-age-value } \* ]** command to check the OSPFv3 LSDB information.

### 1.1.5.2.16 Configuring OSPFv3 IP FRR

If a link fails, OSPFv3 IP FRR rapidly switches traffic to a backup link, which prevents traffic interruption and improves OSPFv3 network reliability.

#### Usage Scenario

As networks develop, services such as Voice over IP (VoIP) and on-line video services require high-quality real-time transmission. However, OSPFv3 takes more than 50 ms to rectify a fault, which cannot meet the requirement for real-time transmission of these services.

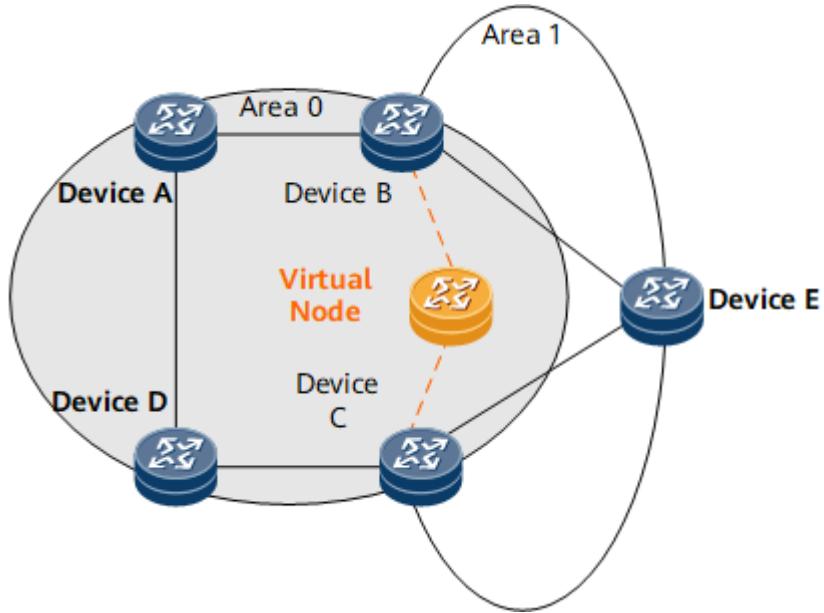

Nevertheless, if an OSPFv3 fault occurs, traffic can be switched to a new link only after the fault detection that lasts several milliseconds, fault notification to the routing control plane that lasts several milliseconds, new topology information generation and flooding that last tens of milliseconds, Shortest Path First (SPF) calculation that lasts tens of milliseconds, and new route notification and adding that last hundreds of milliseconds.

OSPFv3 IP FRR calculates a backup link in advance. If the primary link fails, OSPFv3 IP FRR rapidly switches traffic to the backup link without interrupting traffic. This protects traffic and greatly improves OSPFv3 network reliability.

OSPFv3 IP FRR is applicable to services that are sensitive to the packet delay and packet loss.

OSPFv3 LFA FRR uses the SPF algorithm to calculate the shortest path from each neighbor (root node) that provides a backup link to the destination node and store the node-based backup next hop, which applies to single-node routing scenarios. As networks are increasingly diversified, two ABRs or ASBRs are deployed to improve network reliability. In this case, OSPFv3 FRR in a scenario where multiple nodes advertise the same route is needed. In [Figure 1-186](#), Device B and Device C function as ABRs to forward area 0 and area 1 routes. Device E advertises an intra-area route. Upon receipt of the route, Device B and Device C translate it into a Type 3 LSA and flood the LSA to area 0. After OSPFv3 FRR is enabled on Device A, Device A considers Device B and Device C as its neighbors. Without a fixed neighbor as the root node, Device A fails to calculate FRR backup next hop. To address this problem, a virtual node is simulated between Device B and Device C and used as the root node of Device A, and Device A uses the LFA algorithm to calculate the backup next hop. This solution converts multi-node routing into single-node routing.

**Figure 1-186 OSPFv3 FRR in the scenario where multiple nodes advertise the same route**

After OSPFv3 IP FRR is configured, the lower layer needs to fast respond to a link change so that traffic can be fast switched to the backup link. After FRR and BFD are bound, link failures can be detected rapidly so that traffic is rapidly switched to the backup link if the primary link fails.

## Pre-configuration Tasks

Before configuring OSPFv3 IP FRR, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPFv3 functions](#).

## Enabling OSPFv3 IP FRR

With OSPF IP FRR and loop-free backup links, a device can switch traffic to a backup link immediately if the primary link fails.

## Context

Perform the following steps on the router:

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ] [ vpn-instance vpnname ]**

An OSPFv3 process is enabled, and the OSPFv3 view is displayed.

### Step 3 Run frr

The OSPFv3 IP FRR view is displayed.

### Step 4 Run loop-free-alternate

OSPFv3 IP FRR is enabled, and a loop-free backup link is generated.

OSPFv3 can generate a loop-free backup link only when the OSPFv3 IP FRR traffic protection inequality is met.

### Step 5 (Optional) Run **frr-policy route { route-policy route-policy-name | route-filter route-filter-name }**

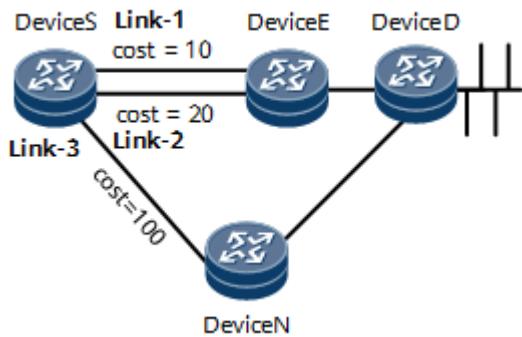

An OSPFv3 IP FRR filtering policy is configured.

After the OSPFv3 IP FRR filtering policy is configured, only the OSPFv3 backup routes that match the filtering rules in the policy can be added to the forwarding table.

### Step 6 (Optional) Run **tiebreaker { node-protecting | lowest-cost } preference preference**

The solution of selecting a backup path for OSPFv3 IP FRR is configured. By default, the solution of selecting a backup path for OSPFv3 IP FRR is node-protection path first. In actual networking scenarios, the solution may need to be changed to smallest-cost path first due to considerations such as interface forwarding capacity and link cost. In **Figure 1-187**, the primary path is Link-1 (DeviceS -> DeviceE -> DeviceD), and Link-2 and Link-3 (DeviceS -> DeviceN -> DeviceD) are backup path candidates. By default, Link-3 is selected as the backup path. To change the solution of selecting a backup path to smallest-cost path first, run the **tiebreaker** command. After the command is run, Link-2 is selected as the backup path.

**Figure 1-187** Solution of selecting a backup path for OSPFv3 IP FRR

### Step 7 Run commit

The configuration is committed.

----End

## (Optional) Binding IP FRR and BFD

Binding IP FRR and BFD enables the lower layer to fast respond to a link change so that traffic can be rapidly switched to the backup link if the primary link fails.

### Context

Binding the BFD session status to the link status of an interface ensures that link failures are detected rapidly and that traffic is rapidly switched to the backup link.

- If IP FRR of an OSPFv3 process is bound to BFD, IP FRR on all interfaces in the OSPFv3 process is bound to BFD.
- If only a small number of interfaces need to have IP FRR bound to BFD, bind IP FRR on each interface to BFD one by one.

Perform the following steps on the router where IP FRR and BFD need to be associated:

### Procedure

- Bind IP FRR and BFD in an OSPFv3 process.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **ospfv3**  
An OSPFv3 process is enabled, and the OSPFv3 view is displayed.
  - c. Run **bfd all-interfaces frr-binding**  
IP FRR and BFD are bound in the OSPFv3 process.
  - d. Run **commit**  
The configuration is committed.
- Bind IP FRR and BFD on a specified OSPFv3 interface.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **interface *interface-type interface-number***  
An interface view is displayed.
  - c. Run **ospfv3 bfd frr-binding**  
IP FRR and BFD are bound on the interface.
  - d. Run **commit**  
The configuration is committed.

----End

### Follow-up Procedure

The BFD configuration on an interface takes precedence over that in an OSPFv3 process. If BFD is enabled on an interface, a BFD session is established based on the BFD parameters set on the interface.

## (Optional) Blocking FRR on an OSPFv3 Interface

If FRR is not required on certain OSPFv3 interfaces, FRR needs to be blocked on these interfaces.

### Context

If an interface runs key services, ensure that the backup path does not pass through this interface so that services will not be affected after FRR calculation.

Perform the following steps on the interfaces of the device where OSPFv3 IP FRR has been configured:

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface *interface-type* *interface-number***

The view of the OSPFv3 interface running FRR is displayed.

#### Step 3 Run **ospfv3 frr block**

FRR is blocked on the OSPFv3 interface.

#### Step 4 Run **commit**

The configuration is committed.

----End

### Verifying the Configuration of OSPFv3 IP FRR

After configuring OSPFv3 IP FRR, you can view information about the primary and backup links.

### Prerequisites

OSPFv3 IP FRR has been configured.

### Procedure

- Run the **display ospfv3 [ *process-id* ] routing verbose** command to view the primary and backup links after OSPFv3 IP FRR is enabled.

----End

### 1.1.5.2.17 Configuring BFD for OSPFv3

To speed up OSPFv3 convergence when the link status changes, you can configure BFD for OSPFv3. After detecting a link failure, BFD notifies the routing protocol of the failure, which triggers fast convergence. When the neighbor relationship is Down, the BFD session is deleted dynamically.

## Usage Scenario

To speed up OSPFv3 convergence when the link status changes, you can configure BFD for OSPFv3 links.

BFD detects links much faster than keep-alive protocols do. If OSPFv3 is bound to BFD sessions, BFD can notify OSPFv3 of link failures immediately, and then OSPFv3 perform route calculation and convergence in the new network topology.

## Pre-configuration Tasks

Before configuring BFD for OSPFv3, complete the following tasks:

- Configure a link layer protocol.
- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPFv3 functions](#).

## Configuring BFD Globally

On the two devices that need to establish a BFD session, you can configure BFD for all the interfaces in a certain OSPFv3 process.

### Context

Perform the following steps on the router that runs OSPFv3:

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **bfd**

BFD is enabled globally.

#### Step 3 Run **commit**

The configuration is committed.

----End

## Configuring BFD for OSPFv3

After enabling BFD for OSPFv3, you need to configure BFD parameters in the OSPFv3 process.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **bfd all-interfaces enable**

BFD is enabled for the OSPFv3 process to create BFD sessions.

### Step 4 (Optional) Run **bfd all-interfaces { min-transmit-interval *Tx-Value* | min-receive-interval *Rx-Value* | detect-multiplier *Mul-Value* }<sup>\*</sup>**

BFD parameters are configured for the OSPFv3 process.

The default interval at which BFD packets are transmitted and the default detection multiplier are recommended. As such, this step can be skipped.

The parameters need to be configured based on network conditions and requirements on network reliability. A short transmission interval for BFD packets can be set for a link that requires higher reliability, and a long transmission interval can be used for a link that has low reliability requirements.

#### NOTE

- Actual interval at which BFD packets are transmitted on the local device = Max { *Tx-Value* (interval at which BFD packets are transmitted) set on the local device, *Rx-Value* (interval at which BFD packets are received) set on the peer device }
- Actual interval at which BFD packets are received on the local device = Max { *Tx-Value* (interval at which BFD packets are transmitted) set on the peer device, *Rx-Value* (interval at which BFD packets are received) set on the local device }
- Actual period for BFD detection on the local device = Actual interval at which BFD packets are received on the local device x Detection multiplier specified by *Mul-Value* on the peer device

For example:

- On the local device, the interval at which packets are transmitted is set to 200 ms, the interval at which packets are received is set to 300 ms, and the detection multiplier is set to 4.
- On the peer device, the interval at which packets are transmitted is set to 100 ms, the interval at which packets are received is set to 600 ms, and the detection multiplier is set to 5.

Then:

- On the local device, the actual interval at which BFD packets are transmitted is 600 ms (calculated by Max { 200 ms, 600 ms }); the actual interval at which BFD packets are received is 300 ms (calculated by Max { 100 ms, 300 ms }); the actual detection period is 1500 ms (calculated by 300 ms x 5).
- On the peer device, the actual interval at which BFD packets are transmitted is 300 ms (calculated by Max { 100 ms, 300 ms }); the actual interval at which BFD packets are received is 600 ms (calculated by Max { 200 ms, 600 ms }); the actual detection period is 2400 ms (calculated by 600 ms x 4).

### Step 5 (Optional) Disable a specified interface from creating a BFD session.

After BFD is configured for an OSPFv3 process, all interfaces on which neighbor relationships are in Full state in the OSPFv3 process create BFD sessions. If BFD is not required on specific interfaces, disable these interfaces from creating BFD sessions.

1. Run **quit**

Return to the system view.

2. Run **interface *interface-type* *interface-number***

The interface view is displayed.

3. Run **ospfv3 bfd block**

The interface is disabled from creating a BFD session.

4. Run **quit**

Return to the system view.

5. Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

**Step 6** (Optional) Run **bfd all-interfaces incr-cost { cost | max-reachable } [ wtr <wtr-value> ]**

The OSPFv3 process is enabled to adjust the cost based on the status of the associated BFD session.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

The delay configured for an interface to restore the cost based on the BFD session status takes precedence over that configured for a process to restore the cost based on the BFD session status.

**Step 7** Run **commit**

The configuration is committed.

----End

## (Optional) Configuring BFD for a Specified Interface

To configure BFD only on a specified interface, or enable an interface to detect link failures faster after BFD for OSPFv3 is enabled globally, configure BFD on the specified interface.

## Context

To configure BFD only on a specified interface, or enable an interface to detect link failures faster after BFD for OSPFv3 is enabled globally, perform the following steps on the interface:

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **interface *interface-type* *interface-number***

The interface view is displayed.

**Step 3** Run **ospfv3 bfd enable [ instance *instance-id* ]**

BFD is enabled on the interface to create BFD sessions.

When BFD is configured globally and the neighbor state is Full, BFD sessions are established using default BFD parameters.

To set parameters for BFD sessions as required, run the **ospfv3 bfd { min-transmit-interval *min-transmit-value* | min-receive-interval *min-receive-value* | detect-multiplier *detect-multiplier-value* | frr-binding } \* [ instance *instance-id* ] }** command.

If BFD for OSPFv3 is configured for an Eth-Trunk with multiple physical interfaces added in a VLAN and **per-link one-arm-echo** is not specified, the BFD session may go down even if only one of the physical interfaces goes down. As a result, the OSPFv3 neighbor relationship also goes down. If **per-link one-arm-echo** is specified in this case, the BFD session goes down only if all the physical interfaces are down, which ensures that the OSPFv3 neighbor relationship can be established normally.

#### NOTE

- The configuration of BFD on an interface takes precedence over that in a process. That is, if BFD session parameters are configured for both a process and an interface, the parameters on the interface will be used to establish BFD sessions on the interface.
- If the parameters of BFD sessions are set but the **ospfv3 bfd enable** command is not run, BFD is not enabled on the interface.

The default interval at which BFD packets are transmitted and the default detection multiplier are recommended. As such, this step can be skipped.

The parameters need to be configured based on network conditions and requirements on network reliability. A short transmission interval for BFD packets can be set for a link that requires higher reliability, and a long transmission interval can be used for a link that has low reliability requirements.

#### NOTE

- Actual interval at which BFD packets are transmitted on the local device = Max { *min-transmit-value* (interval at which BFD packets are transmitted) set on the local device, *min-receive-value* (interval at which BFD packets are received) set on the peer device }
- Actual interval at which BFD packets are received on the local device = Max { *min-transmit-value* (interval at which BFD packets are transmitted) set on the peer device, *min-receive-value* (interval at which BFD packets are received) set on the local device }
- Actual period for BFD detection on the local device = Actual interval at which BFD packets are received on the local device x Detection multiplier specified by *detect-multiplier-value* on the peer device

For example:

- On the local device, the interval at which BFD packets are transmitted is set to 200 ms, the interval at which BFD packets are received is set to 300 ms, and the detection multiplier is set to 4.
- On the peer device, the interval at which BFD packets are transmitted is set to 100 ms, the interval at which BFD packets are received is set to 600 ms, and the detection multiplier is set to 5.

Then:

- On the local device, the actual interval at which BFD packets are transmitted is 600 ms (calculated through Max { 200 ms, 600 ms }); the actual interval at which BFD packets are received is 300 ms (calculated through Max { 100 ms, 300 ms }); the actual detection period is 1500 ms (calculated through 300 ms x 5).
- On the peer device, the actual interval at which BFD packets are transmitted is 300 ms (calculated through Max { 100 ms, 300 ms }); the actual interval at which BFD packets are received is 600 ms (calculated through Max { 200 ms, 600 ms }); the actual detection period is 2400 ms (calculated through 600 ms x 4).

**Step 4** (Optional) Run **ospfv3 bfd incr-cost { cost | max-reachable } [ wtr <wtr-value> ]**

The OSPFv3 interface is enabled to adjust the cost based on the BFD session status.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

**Step 5** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration of BFD for OPSFv3

After configuring BFD for OSPFv3, verify information about the BFD session.

## Prerequisites

BFD for OSPFv3 has been configured.

## Procedure

- Run the **display ospfv3 [ process-id ] bfd session [ interface-type interface-number ] [ neighbor-id ] [ verbose ]** command to check information about the BFD session.

----End

### 1.1.5.2.18 Configuring OSPFv3 Authentication

Configuring OSPFv3 authentication enables a device to authenticate sent and received OSPFv3 packets, protecting the device against attacks through forged OSPFv3 packets.

## Usage Scenario

OSPFv3 IPsec uses a complete set of IPsec mechanisms to authenticate sent and received OSPFv3 packets, protecting devices against forged OSPFv3 packets.

However, on some special networks, a mobile ad hoc network (MANET) for example, IPsec is difficult to deploy and maintain. To address this problem, Authentication Trailer for OSPFv3 can be used to implement authentication.

If Authentication Trailer for OSPFv3 is used, an authentication field is added to each OSPFv3 packet for encryption. When receiving an OSPFv3 packet from a remote device, the local device discards the packet if the authentication password carried in the packet is different from the local one, protecting the local device against potential attacks.

## Pre-configuration Tasks

Before configuring OSPFv3 authentication, complete the following tasks:

- Enable IPv6.
- **Configure basic OSPFv3 functions.**
- If keychain authentication needs to be used, configure basic keychain functions.

## Configuring OSPFv3 IPsec

OSPFv3 IPsec provides a set of IPsec mechanisms to authenticate sent and received OSPFv3 packets, protecting devices against invalid OSPFv3 packets.

## Usage Scenario

OSPFv3 IPsec uses a set of IPsec mechanisms to authenticate sent and received OSPFv3 packets, protecting devices against invalid OSPFv3 packets.

### ?1. Configuring an IPsec Proposal

Proposal defines encryption and authentication algorithms to authenticate OSPFv3 protocol packets.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run ipsec proposal *proposal-name*

A security proposal is created and the security proposal view is displayed.

### Step 3 Run encapsulation-mode transport

The protocol packet encapsulation mode is configured.

### Step 4 (Optional) Run transform { ah | esp | ah-esp }

A security protocol is configured.

Because AH does not support encryption in IPsec scenarios, ESP is recommended.

### Step 5 An authentication algorithm and an encryption algorithm are configured based on the selected security protocol.

- If Authentication Header (AH) is configured, run the **ah authentication-algorithm { md5 | sha1 | sha2-256 | sha2-384 | sha2-512 }** command to configure an authentication algorithm.

To help provide high security, do not use the MD5 or SHA1 algorithm as an AH authentication algorithm.

- If ESP is configured, run the **esp authentication-algorithm { md5 | sha1 | sha2-256 | sha2-384 | sha2-512 }** command to configure an authentication algorithm.

 **NOTE**

To help provide high security, do not use the MD5 or SHA1 algorithm as an ESP authentication algorithm.

- If ESP is configured, run the **esp encryption-algorithm { des | 3des | aes { 128 | 192 | 256 } }** command to configure an ESP encryption algorithm.

 **NOTE**

To help provide high security, do not use the DES or 3DES algorithm as an ESP encryption algorithm.

**Step 6 Run commit**

The configuration is committed.

----End

## ??. Configuring an IPsec SA

To create a manual IPsec tunnel, you need to use the SPI, string-key, authentication-hex, or encryption-hex.

### Procedure

**Step 1 Run system-view**

The system view is displayed.

**Step 2 Run ipsec sa *sa-name***

An SA is created, and the SA view is displayed.

**Step 3 Run proposal *proposal-name***

A security proposal is applied to the SA.

 **NOTE**

A security proposal must be configured before it can be associated with protocol packet flows.

One SA can use only one security proposal. If a security proposal has been applied to an SA, the SA can use another security proposal only after the original one is deleted.

**Step 4 Run sa spi { inbound | outbound } { ah | esp } *spi-number***

An SPI is set.

 **NOTE**

The SPI uniquely identifies an SA. The inbound and outbound SPIs are set, and the inbound SPI on the local end must be the same as the outbound SPI on the peer end.

**Step 5 To configure the authentication key, run either of the following commands:**

1. Run **sa authentication-hex { inbound | outbound } { ah | esp } [ cipher ] *key-cipher-key***

- An authentication key in hexadecimal format or ciphertext is set.
2. Run **sa string-key { inbound | outbound } { ah | esp } [ cipher ] string-cipher-key**

An authentication key in string format is set.

 NOTE

An authentication key for outgoing protocol packets on the local end must be identical with that for incoming protocol packets on the peer end.

If multiple authentication keys are configured, the latest one takes effect.

Updating keys periodically is recommended.

- Step 6** (Optional) Run **sa encryption-hex { inbound | outbound } esp [ cipher ] hex-cipher-key**

An encryption key is set.

- Step 7** Run **commit**

The configuration is committed.

----End

### ?.3. Enabling OSPFv3 IPsec

A Security Association (SA) configured in an OSPFv3 process or OSPFv3 area is used to authenticate packets of the process.

#### Context

Perform the following steps on the router that runs OSPFv3:

#### Procedure

- Enable IPsec in an OSPFv3 process.
  - a. Run **system-view**

The system view is displayed.
  - b. Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.
  - c. Run **ipsec sa sa-name**

An SA is configured in the process.

An OSPFv3 process can be associated with multiple OSPFv3 areas. An SA applied in the OSPFv3 process can be used in the associated areas.
  - d. Run **commit**

The configuration is committed.
- Enable IPsec in an OSPFv3 area.
  - a. Run **system-view**

The system view is displayed.
  - b. Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

- c. Run **area area-id**

The OSPFv3 area view is displayed.

- d. Run **ipsec sa sa-name**

An SA is configured in the OSPFv3 area.

 NOTE

The SA configured on an OSPFv3 area takes precedence over that configured in an OSPFv3 process.

- e. Run **commit**

The configuration is committed.

- Enable IPsec in an OSPFv3 area.

- a. Run **system-view**

The system view is displayed.

- b. Run **interface interface-type interface-number**

The interface view is displayed.

- c. Run **ospfv3 ipsec sa sa-name**

An SA in the view of an OSPFv3 interface is configured.

 NOTE

- The SA configured in the interface view takes precedence over that configured in the OSPFv3 area view or the OSPFv3 process view.
- The **ospfv3 ipsec sa** command can be used on all the OSPFv3 instances of an interface.

- d. Run **commit**

The configuration is committed.

----End

## Configuring OSPFv3 Authentication Trailer

Open Shortest Path First version 3 (OSPFv3) supports packet authentication, enabling OSPFv3 devices to receive only the OSPFv3 packets that are authenticated. If packets fail to be authenticated, OSPFv3 neighbor relationships cannot be established. This section describes how to configure an authentication mode.

## Usage Scenario

OSPFv3 authentication trailer supports HMAC-SHA256 authentication and HMAC-SM3 authentication.

 NOTE

By default, authentication is not configured for OSPFv3 areas, processes, or interfaces. You are advised to configure an authentication mode to ensure system security.

For security purposes, you are advised not to use weak security algorithms in OSPFv3. If you need to use such an algorithm, run the **undo crypto weak-algorithm disable** command to enable the weak security algorithm function first.

When configuring an authentication password, select the ciphertext mode because the password is saved in the configuration file as a plaintext if you select the plaintext mode, which has a high risk. To ensure device security, change the password periodically.

## Procedure

- Configure area authentication.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **ospfv3 [ process-id ]**  
The OSPFv3 view is displayed.
  - c. Run **area area-id**  
The OSPFv3 area view is displayed.
  - d. Run **authentication-mode { hmac-sha256 | hmac-sm3 } key-id KeyId { plain PlainText | [ cipher ] CipherText }**  
An authentication mode is configured for the OSPFv3 area.

 NOTE

When area authentication is used, all the routers in the area must have the same area authentication mode and password.

- e. Run **commit**  
The configuration is committed.
- Configure process authentication.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **ospfv3 [ process-id ]**  
The OSPFv3 view is displayed.
  - c. Run **authentication-mode { hmac-sha256 | hmac-sm3 } key-id KeyId { plain PlainText | [ cipher ] CipherText }**  
An authentication mode is configured for the OSPFv3 process.
  - d. Run **commit**  
The configuration is committed.
- Configure interface authentication.
  - a. Run **system-view**  
The system view is displayed.

- b. Run **interface interface-type interface-number**  
The interface view is displayed.
- c. Run **ospfv3 authentication-mode { hmac-sha256 | hmac-sm3 } key-id KeyId { plain PlainText | [ cipher ] CipherText } [ instance instanceId ]**  
An authentication mode is configured for the OSPFv3 interface.

 NOTE

Interface authentication takes precedence over area authentication. For interfaces on the same subnet, the configured authentication mode and password must be identical. This requirement does not apply to the interfaces on different subnets.

- d. Run **commit**

The configuration is committed.

----End

## Configuring OSPFv3 Process Authentication

OSPFv3 supports packet authentication, with which devices accept only the OSPFv3 packets that are authenticated. If OSPFv3 packets fail to be authenticated, OSPFv3 neighbor relationships cannot be established. Configuring OSPFv3 process authentication improves OSPFv3 network security.

## Context

With the increase in attacks on TCP/IP networks and inherent defects and flawed implementation of the TCP/IP protocol suite, the attacks have increasing impacts on the networks. Attacks on network devices may even cause a network crash or lead to network unavailability. Configuring OSPFv3 process authentication improves OSPFv3 network security.

 NOTE

By default, no authentication mode is configured for an OSPFv3 process. You are advised to configure an authentication mode to ensure system security.

OSPFv3 authentication takes effect in descending order of priority as follows: interface authentication, area authentication, and process authentication.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Configure an authentication mode for the OSPFv3 process as required.

- To configure the HMAC-SHA256 or HMAC-SM3 authentication mode for the OSPFv3 process, run the **authentication-mode { hmac-sha256 | hmac-sm3 } key-id KeyId { plain PlainText | [ cipher ] CipherText } command**.

If you choose **plain**, the password will be saved as a cleartext in the configuration file, which provokes high security risks. To improve system

- security, choose ciphertext authentication and change the password periodically.
- To configure keychain authentication for the OSPFv3 process, run the **authentication-mode { keychain *Keychain-Name* }** command.

 **NOTE**

Before configuring keychain authentication, you need to run the **keychain** command to create a keychain, and then run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm, respectively, for this keychain. Otherwise, OSPFv3 authentication will fail.

**Step 4 Run commit**

The configuration is committed.

----End

## Configuring OSPFv3 Area Authentication

OSPFv3 supports packet authentication, with which devices accept only the OSPFv3 packets that are authenticated. If OSPFv3 packets fail to be authenticated, OSPFv3 neighbor relationships cannot be established. Configuring OSPFv3 area authentication improves OSPFv3 network security.

## Context

With the increase in attacks on TCP/IP networks and inherent defects and flawed implementation of the TCP/IP protocol suite, the attacks have increasing impacts on the networks. Attacks on network devices may even cause a network crash or lead to network unavailability. Configuring OSPFv3 area authentication improves OSPFv3 network security. If area authentication is used, the authentication mode and password configurations on all the interfaces in the area must be identical.

 **NOTE**

By default, no authentication mode is configured for an OSPFv3 area. For security purposes, you are advised to configure an authentication mode.

OSPFv3 authentication takes effect in descending order of priority as follows: interface authentication, area authentication, and process authentication.

## Procedure

**Step 1 Run system-view**

The system view is displayed.

**Step 2 Run ospfv3 [ *process-id* ]**

The OSPFv3 view is displayed.

**Step 3 Run area *area-id***

The OSPFv3 area view is displayed.

**Step 4 Configure an authentication mode for the OSPFv3 area as required.**

- To configure the HMAC-SHA256 or HMAC-SM3 authentication mode for the OSPFv3 area, run the **authentication-mode { hmac-sha256 | hmac-sm3 }** **key-id KeyId { plain PlainText | [ cipher ] CipherText }** command.  
If you choose **plain**, the password will be saved as a cleartext in the configuration file, which provokes high security risks. To improve system security, choose ciphertext authentication and change the password periodically.
- To configure keychain authentication for the OSPFv3 area, run the **authentication-mode { keychain Keychain-Name }** command.

 **NOTE**

Before configuring keychain authentication, you need to run the **keychain** command to create a keychain, and then run the **key-id**, **key-string**, and **algorithm** commands to configure a key ID, a password, and an authentication algorithm, respectively, for this keychain. Otherwise, OSPFv3 authentication will fail.

#### Step 5 Run commit

The configuration is committed.

----End

### Configuring OSPFv3 Interface Authentication

OSPFv3 supports packet authentication, with which devices accept only the OSPFv3 packets that are authenticated. If OSPFv3 packets fail to be authenticated, OSPFv3 neighbor relationships cannot be established. Configuring OSPFv3 interface authentication improves OSPFv3 network security.

### Context

With the increase in attacks on TCP/IP networks and inherent defects and flawed implementation of the TCP/IP protocol suite, the attacks have increasing impacts on the networks. Attacks on network devices may even cause a network crash or lead to network unavailability. Configuring OSPFv3 interface authentication improves OSPFv3 network security. Interface authentication takes effect between neighboring devices' interfaces on which an authentication mode and password are configured. Interface authentication takes precedence over area authentication. For interfaces on the same subnet, the configured authentication mode and password must be identical. This requirement does not apply to the interfaces on different subnets.

 **NOTE**

By default, no authentication mode is configured for an OSPFv3 interface. For security purposes, you are advised to configure an authentication mode.

OSPFv3 authentication takes effect in descending order of priority as follows: interface authentication, area authentication, and process authentication.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run `interface interface-type interface-number`

The interface view is displayed.

### Step 3 Configure an authentication mode for the OSPFv3 interface as required.

- To configure the HMAC-SHA256 or HMAC-SM3 authentication mode for the OSPFv3 interface, run the `ospfv3 authentication-mode { hmac-sha256 | hmac-sm3 } key-id KeyId { plain PlainText | [ cipher ] CipherText } [ instance instanceld ]` command.  
If you choose **plain**, the password will be saved as a cleartext in the configuration file, which provokes high security risks. To improve system security, choose ciphertext authentication and change the password periodically.
- To configure keychain authentication for the OSPFv3 interface, run the `ospfv3 authentication-mode { keychain Keychain-Name } [ instance instanceld ]` command.

#### NOTE

Before configuring keychain authentication, you need to run the `keychain` command to create a keychain, and then run the `key-id`, `key-string`, and `algorithm` commands to configure a key ID, a password, and an authentication algorithm, respectively, for this keychain. Otherwise, OSPFv3 authentication will fail.

### Step 4 Run `commit`

The configuration is committed.

----End

## Verifying the Configuration

After configuring OSPFv3 authentication, you can check the configurations.

## Prerequisites

OSPFv3 authentication has been configured.

## Procedure

- Run the `display ospfv3 [ process-id ]` command to view the SA applied in a specified process.
- Run the `display ospfv3 [ process-id ] area [ area-id ]` command to view the SA applied in a specified area.
- Run the `display ospfv3 [ process-id ] interface [ area { area-id | area-id|ipv4 } ] [ interfaceType interfaceNum | interfaceName ]` command to check the SA applied to the interface.

----End

### 1.1.5.2.19 Configuring OSPFv3 Fast Convergence

By adjusting OSPFv3 timers, you can implement OSPF fast network convergence.

## Pre-configuration Tasks

Before configuring OSPFv3 fast convergence, complete the following tasks:

- Configure a link layer protocol.
- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPFv3 functions](#).

## Setting the Interval at Which Hello Packets Are Sent

You can adjust the value of the Hello timer to change the speed of OSPFv3 neighbor relationship establishment and the network convergence speed.

### Context

Hello packets are periodically sent to the neighbor router to detect and maintain the neighbor relationship and to elect the DR and the BDR. Based on standard protocols, the Hello timer values of neighbors must be the same. The value of the Hello timer is inversely proportional to the route convergence speed and network load.

### Procedure

#### Step 1 Run `system-view`

The system view is displayed.

#### Step 2 Run `interface interface-type interface-number`

The interface view is displayed.

#### Step 3 Run `ospfv3 timer hello interval [ conservative ] [ instance instance-id ]`

The interval at which the interface sends Hello packets is set.

The **conservative** parameter indicates that the conservative mode is enabled for the neighbor dead timer. If the conservative mode is enabled, the value configured for the dead timer using the `ospfv3 timer dead` command takes effect even when the value is less than 10s.

To speed up OSPFv3 convergence in the case of a link failure, configuring BFD for OSPFv3 is recommended. If the remote end does not support BFD for OSPFv3 or the user does not want to have BFD for OSPFv3 enabled, you are advised to specify **conservative** when running the `ospfv3 timer hello` command. In conservative mode, the value set for the dead timer using the `ospfv3 timer dead` command takes effect even if the value is less than 10 seconds; otherwise, route convergence is performed based on the OSPFv3 neighbor dead timer, which takes a long time and has a great impact on services.

#### NOTE

This interval must not be less than the time taken to perform an active/standby switchover. Otherwise, an intermittent protocol interruption may occur during a switchover. The default timer value is recommended.

#### Step 4 Run commit

The configuration is committed.

----End

### Setting the Dead Time of the Neighbor Relationship

If a device does not receive a Hello packet from its neighbor within the dead interval, the device considers the neighbor Down.

### Context

Perform the following steps on the OSPFv3 router:

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run interface *interface-type interface-number*

The interface view is displayed.

#### Step 3 Run ospfv3 timer dead *interval* [ *instance instance-id* ]

A dead timer is configured for the neighboring router.

#### NOTE

If the dead timer is shorter than 10s, the neighbor relationship may be torn down. To prevent this issue, the dead timer of 10 seconds takes effect if the value of **dead interval** is less than 10 seconds. However, if the **ospfv3 timer hello** command is run, the **conservative** parameter is specified to enable the conservative mode for the neighbor dead timer, and the configured dead timer is less than 10s, the system still uses the configured value to determine whether a neighbor is down.

#### Step 4 Run commit

The configuration is committed.

----End

### Configuring OSPFv3 Sham Hello

With OSPFv3 sham hello, device can exchange Hello and LSU and LSAck packets to maintain OSPFv3 neighbor relationships, which strengthens the neighbor detection mechanism.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run ospfv3 [ *process-id* ]

The OSPFv3 view is displayed.

**Step 3 Run sham-hello enable**

OSPFv3 sham hello is enabled.

**Step 4 Run commit**

The configuration is committed.

----End

## Setting the Interval at Which LSAs Are Updated

You can set the interval at which LSAs are updated based on network connections and router resources.

### Context

To prevent excessive consumption of network bandwidth and router resources caused by frequent network connection or route flapping, you can set the **intelligent-timer** parameter to specify the interval for updating LSAs on a stable network that requires fast route convergence. In this manner, topology or route changes can be immediately advertised to the network through LSAs, speeding up route convergence on the network.

### Procedure

**Step 1 Run system-view**

The system view is displayed.

**Step 2 Run ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

**Step 3 Run lsa-originate-interval { 0 | intelligent-timer max-interval start-interval hold-interval [ other-type interval ] | other-type interval [ intelligent-timer max-interval start-interval hold-interval ] }**

The device is configured to set the interval for updating OSPFv3 LSAs based on the intelligent SPF timer.

**Step 4 (Optional) Run lsa-originate-interval suppress-flapping interval [ threshold count ]**

The suppression period that takes effect when sent OSPFv3 LSAs flap is configured.

If no flapping occurs among sent OSPFv3 LSAs, the configuration of the **lsa-originate-interval** command prevents the device from frequently sending LSAs. If sent OSPFv3 LSAs flap, the configuration of the **lsa-originate-interval suppress-flapping** command minimizes the impact of the flapping on services. The larger value of the two intervals is used as the suppression period.

**Step 5 Run commit**

The configuration is committed.

----End

## Setting the Interval at Which LSAs Are Received

You can set the interval at which LSAs are received based on network connections and router resources.

### Context

Setting the interval at which LSAs are received can prevent network connections or frequent route flapping from causing frequent update of LSAs. After the interval is set on a router, the router updates an LSA only after the specified interval expires.

On a stable network that requires fast route convergence, you can change the interval at which OSPFv3 LSAs are received to 0s. In this manner, the device can fast respond to topology or route changes, which speeds up route convergence.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

#### Step 3 Run **lsa-arrival-interval { interval | intelligent-timer max-interval start-interval hold-interval }**

The interval at which LSAs are received is configured.

#### Step 4 (Optional) Run **lsa-arrival-interval suppress-flapping interval [ threshold count ]**

The suppression period that takes effect when received OSPFv3 LSAs flap is configured.

If no flapping occurs among received OSPFv3 LSAs, the configuration of the **lsa-arrival-interval** command prevents the device from frequently receiving LSAs. If received OSPFv3 LSAs flap, the configuration of the **lsa-arrival-interval suppress-flapping** command minimizes the impact of the flapping on services. The larger value of the two intervals is used as the suppression period.

#### Step 5 Run **commit**

The configuration is committed.

----End

## Setting a Period During Which OSPFv3 Keeps the Maximum Cost in Local LSAs

When an OSPFv3 interface changes from down to up, if a period during which OSPFv3 keeps the maximum cost in local LSAs is configured, traffic is switched back to the recovered link only after the period elapses.

### Context

When an OSPFv3 interface changes from down to up, the OSPFv3 neighbor relationship is re-established. After OSPFv3 routes converge, traffic is switched

back. Because OSPFv3 route convergence is very fast, many services that depend on OSPFv3 routes may require delayed OSPFv3 route switchback. In this case, you can run the **ospfv3 peer hold-max-cost** command to specify a period during which OSPFv3 keeps the maximum cost in local LSAs. After the OSPFv3 neighbor relationship reaches Full state, the traffic forwarding path remains unchanged during the specified period. After this period expires, the maximum cost is restored to the original cost of the recovered link, and traffic is switched back to the recovered link.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The view of the interface that will run OSPFv3 is displayed.

### Step 3 Run **ipv6 enable**

IPv6 is enabled on the specified interface.

### Step 4 Run **ospfv3 process-id area area-id [ instance instance-id ]**

An OSPFv3 process is enabled, and the area to which the process belongs is specified.

### Step 5 Run **ospfv3 peer hold-max-cost timer hold-max-cost-value [ instance instance-id ]**

The period during which OSPFv3 keeps the maximum cost in local LSAs is set.

### Step 6 Run **commit**

The configuration is committed.

----End

## Disabling OSPFv3 LSA Aging Management

By default, the OSPFv3 LSA aging management function is enabled. To disable this function, perform this task.

## Context

LSAs are aged out if their LS age field encounters an exception, and this may cause LSA flapping or incorrect route calculation. For example, if the aging time carried in a received LSA is 2500 seconds, the device considers the LSA abnormal and reduces the aging time to 500 seconds. As a result, the LSA is aged out far sooner than expected. To address this issue, the OSPFv3 LSA aging management function is enabled by default. If the aging time in a received LSA is longer than 1800 seconds, OSPFv3 considers the LSA abnormal and changes the aging time to 1700 seconds. This operation is performed for each abnormal LSA until the aging time values of all LSAs in the area are the same. This ensures that routes can be calculated correctly.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **lsa-age refresh disable**

OSPFv3 LSA aging management is disabled.

### Step 4 Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After configuring OSPFv3 fast convergence, verify brief information about OSPFv3.

## Prerequisites

OSPFv3 fast convergence has been configured.

## Procedure

- Run the **display ospfv3 [ process-id ] interface [ area area-id ] [ interface-type interface-number ]** command to view information about an OSPFv3 interface.
- Run the **display ospfv3 [ process-id ]** command to check brief OSPFv3 information.

----End

### 1.1.5.2.20 Configuring the OSPFv3 GR Helper

To avoid traffic interruption and route flapping caused by the active/standby switchover, you can enable OSPFv3 GR.

## Context

GR ensures normal traffic forwarding and non-stop forwarding of key services during the restart of routing protocols. GR is one of high availability (HA) technologies. HA technologies comprise a set of comprehensive techniques, such as fault-tolerant redundancy, link protection, faulty node recovery, and traffic engineering. As a fault-tolerant redundancy technology, GR is widely used to ensure non-stop forwarding of key services during master/slave main control board switchover and system upgrade.

#### NOTE

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports only the GR Helper.

## Pre-configuration Tasks

Before configuring OSPFv3 GR, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- **Configure basic OSPFv3 functions.**

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 process-id**

The OSPFv3 view is displayed.

### Step 3 Configure a basic ACL:

1. Run **helper-role [ { ip-prefix ip-prefix-name | acl-number acl-number | acl-name acl-name } | max-grace-period period | planned-only | lsa-checking-ignore ]**\*

OSPFv3 GR is enabled.

2. Run **quit**

Return to the system view.

3. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**

The ACL view is displayed.

4. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ]**\*

A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

### Step 4 Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

Run the following command to check the preceding configuration:

- Run the **display ospfv3 [ process-id ] graceful-restart-information** command to view the OSPFv3 GR Helper status.

### 1.1.5.2.21 Configuring OSPFv3 to Report Network Topology Information to BGP-LS

After OSPFv3 topology information is advertised to BGP-LS, BGP-LS reports the information to a controller, which implements path planning.

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **ospfv3 [ process-id ]**

OSPFv3 is enabled, and the OSPFv3 view is displayed.

##### Step 3 Run **bgp-ls enable**

The OSPFv3 process is enabled to advertise topology information.

##### Step 4 Run **bgp-ls identifier [ identifier-value ]**

OSPFv3 topology advertisement is configured, and a topology ID is specified.

##### Step 5 Run **commit**

The configuration is committed.

----End

### 1.1.5.2.22 Improving OSPFv3 Network Stability

A stable OSPFv3 network features less route flapping, normal router performance, and high network performance.

#### Usage Scenario

By setting timers, you can reduce the number of unnecessary packets on networks and the load on the device, and improve network performance.

By adjusting the SPF calculation interval, you can mitigate resource consumption due to frequent network changes.

#### Pre-configuration Tasks

Before improving the security of an OSPFv3 network, complete the following tasks:

- Configure a link layer protocol.
- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [Configure basic OSPF3 functions](#).

#### Setting the OSPFv3 Preference

If multiple dynamic routing protocols run on a device, the device needs to select optimal routes from the routes of these protocols. In this case, you can set a priority for each routing protocol. In this manner, when different protocols discover

the routes to the same destination, the route discovered by the protocol with the highest priority is selected.

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

**Step 3** Run **preference [ ase ] { preference | route-policy route-policy-name | route-filter route-filter-name } \***

A preference is set for OSPFv3.

**Step 4** Run **commit**

The configuration is committed.

----End

## Setting the Delay in Transmitting LSAs on the Interface

It takes time to transmit OSPFv3 packets on a link. Therefore, a certain delay is added to the aging time of an LSA before the LSA is sent. This configuration is especially necessary on low-speed links.

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **interface interface-type interface-number**

The OSPFv3 interface view is displayed.

**Step 3** Run **ospfv3 trans-delay interval [ instance instance-id ]**

The delay in transmitting LSAs is set on the interface.

**Step 4** Run **commit**

The configuration is committed.

----End

## Setting the Interval at Which LSAs Are Retransmitted Between Adjacent Routers

You can set an appropriate interval at which LSAs are retransmitted based on network conditions in order to accelerate convergence.

## Context

After sending an LSA to its neighbor, a device waits for a response. If the device does not receive an acknowledgement packet within the Nth LSA retransmission interval, the device retransmits the LSA to the neighbor.

First LSA retransmission interval = Configured interval at which LSAs are retransmitted, which is *interval*

Second LSA retransmission interval = Configured interval at which LSAs are retransmitted, which is *interval*

Third LSA retransmission interval = Configured interval at which LSAs are retransmitted, which is *interval*

Fourth LSA retransmission interval = Configured interval at which LSAs are retransmitted (*interval*) x 2

Fifth LSA retransmission interval = Configured interval at which LSAs are retransmitted (*interval*) x 2<sup>2</sup>

... ...

Nth LSA Retransmission Interval = Configured interval at which LSAs are retransmitted (*interval*) x 2^(n-3).

If *interval* x 2^(n-3) is greater than 30, the Nth LSA retransmission interval is 30.

If the configured interval at which LSAs are retransmitted (*interval*) is greater than 30, the Nth LSA retransmission interval equals *interval*.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The OSPFv3 interface view is displayed.

### Step 3 Run **ospfv3 timer retransmit interval [ instance instance-id ]**

An interval for retransmitting LSAs to the adjacent device is configured.

Set the LSA retransmission interval to a proper value. An excessively short interval will cause unnecessary retransmission. Generally, the interval should be longer than the time taken for round-trip packet transmission between two ends.

### Step 4 Run **commit**

The configuration is committed.

----End

## Configuring a Route Calculation Delay to Suppress Frequent LSA Flapping

### Context

Frequent OSPFv3 LSA flapping may lead to route flapping, adversely affecting services. To address this problem, run the **maxage-lsa route-calculate-delay** command to configure the device to delay route calculation when it receives a MaxAge Router LSA, which suppresses the frequent OSPFv3 LSA flapping that may occur.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

### Step 3 Run **maxage-lsa route-calculate-delay delay-interval**

A route calculation delay is configured and will be triggered when the device receives a MaxAge Router LSA.

### Step 4 Run **commit**

The configuration is committed.

----End

## Configuring the SPF Timer

By setting the interval for Shortest Path First (SPF) calculation, you can reduce resource consumption caused by frequent network changes.

## Context

Whenever the Link-state Database (LSDB) of OSPFv3 changes, the shortest path should be recalculated. Calculating the shortest path each time the LSDB changes consumes enormous resources and lowers the efficiency of the device. In this case, you can adjust values of *delay-interval* and *hold-interval* to prevent bandwidth exhaustion and route consumption caused by frequent network changes. You can use the **intelligent-timer** parameter to configure the device to perform SPF calculation at an interval (at the millisecond level) based on an intelligent timer. This speeds up network convergence.

## Procedure

- Configure an SPF normal timer.

- Run **system-view**

The system view is displayed.

- Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

- Run **spf timers delay-interval hold-interval**

An SPF normal timer is configured.

- Run **commit**

The configuration is committed.

- Configure an SPF intelligent timer.

- Run **system-view**

The system view is displayed.

b. Run **ospfv3** [*process-id*]

The OSPFv3 view is displayed.

c. Run **spf-schedule-interval** { *delay-interval hold-interval* | **intelligent-timer** *max-interval start-interval hold-interval-1 millisecond interval2* }

The SPF intelligent timer is set.

The interval for SPF calculation based on the intelligent timer is described as follows:

- i. The initial interval for SPF calculation is specified by *start-interval*.
- ii. The interval for SPF calculation for the nth ( $n \geq 2$ ) time equals *hold-interval-1*  $\times 2^{(n - 2)}$ .
- iii. After the interval specified by *hold-interval-1*  $\times 2^{(n - 2)}$  reaches the maximum interval specified by *max-interval*, OSPFv3 keeps using the maximum interval for SPF calculation.
- iv. If no flapping occurs during the interval from the end of the last SPF calculation to the start of the next SPF calculation, and the interval exceeds the maximum interval specified by *max-interval*, the intelligent timer exits.
- v. If no flapping occurs in the previous interval but occurs in the current interval, SPF calculation is delayed for a period of *start-interval*. After the SPF calculation is complete, the current interval will be applied when waiting for the next SPF calculation.

 NOTE

The normal SPF timer and intelligent SPF timer are mutually exclusive.

d. Run **commit**

The configuration is committed.

----End

## Configuring a Stub Router

When the device is overloaded and cannot forward any other packets, you can configure it as a stub router. After the router is configured as a stub router, other OSPFv3 devices do not use this device to forward data, but they can have a route to this stub router.

## Context

A stub router controls traffic and instruct other OSPFv3 devices not to use it to forward data. Other OSPFv3 devices can have a route to the stub router.

The link cost in the Router LSAs generated by the stub router is set to the maximum value (65535).

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

**Step 2** Run **ospfv3 [ process-id ]**

The OSPFv3 view is displayed.

**Step 3** Run **stub-router [[ on-startup [ interval ] ] | [ intra-area-prefix-lsa ] | [ external-lsa [ externallsa-metric ] ] | [ inter-area-prefix-lsa [ interareaprefixlsa\_metric ] ] ]\***

A stub router is configured.

The parameter **on-startup [ interval ]** specifies the interval during which the device remains a stub router.

 **NOTE**

The stub router configured through this command has nothing to do with the routers in a stub area.

**Step 4** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After improving the OSPFv3 network stability, verify brief information about OSPFv3 and the IP routing table.

## Procedure

- Run the **display ospfv3 [ process-id ] interface [ no-peer | area area-id ] [ interface-type interface-number ]** command to view information about an OSPFv3 interface.
- Run the **display ospfv3 [ process-id ] routing** command to check information about the OSPFv3 routing table.
- Run the **display ospfv3 [ process-id ] statistics maxage-lsa** command to check information about MaxAge Router-LSAs.

----End

### 1.1.5.2.23 Configuring the Network Management Function of OSPFv3

OSPFv3 supports the network management function. You can configure the OSPFv3 Management Information Base (MIB) and bind it to an OSPFv3 process through Simple Network Management Protocol (SNMP). In this manner, the OSPFv3 MIB manages multicast information exchanged between the Network Management Station (NMS) and agents.

## Pre-configuration Tasks

Before configuring the network management function of OSPFv3, complete the following tasks:

- Configure a link layer protocol.
- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.

- **Configure basic OSPFv3 functions.**

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ospfv3 mib-binding process-id**

The OSPFv3 process is bound to the MIB.

### Step 3 Run **commit**

The configuration is committed.

----End

## Checking the Configurations

Run the following command to check the previous configuration:

- Run the **display current-configuration** command to check whether an OSPFv3 process has been bound to the OSPFv3 MIB.

### 1.1.5.2.24 Whitelist Session-CAR for OSPFv3

You can configure whitelist session-CAR for OSPFv3 to isolate bandwidth resources by session for OSPFv3 packets. This configuration prevents bandwidth preemption among OSPFv3 sessions in the case of a traffic burst.

## Context

When OSPFv3 packets suffer a traffic burst, bandwidth may be preempted among different OSPFv3 sessions. To resolve this problem, you can configure whitelist session-CAR for OSPFv3 to isolate bandwidth resources by session. If the default parameters of whitelist session-CAR for OSPFv3 do not meet service requirements, you can adjust them as required.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **whitelist session-car ospfv3 { cir cir-value | cbs cbs-value | pir pir-value | pbs pbs-value } \***

Parameters of whitelist session-CAR for OSPFv3 are configured.

In normal cases, you are advised to use the default values of these parameters.

### Step 3 (Optional) Run **whitelist session-car ospfv3 disable**

Whitelist session-CAR for OSPFv3 is disabled.

By default, whitelist session-CAR for OSPFv3 is enabled. In normal cases, you are advised to keep this function enabled. Disable it if it becomes abnormal or adversely affects other services.

#### Step 4 Run commit

The configuration is committed.

----End

### Verifying the Configuration

After configuring whitelist session-CAR for OSPFv3, verify the configuration.

- Run the **display cpu-defend whitelist-v6 session-car ospfv3 statistics slot slot-id** command to check statistics about whitelist session-CAR for OSPFv3 on a specified interface board.

#### 1.1.5.2.25 Configuring Micro-Isolation CAR for OSPFv3

By default, micro-isolation CAR is enabled for OSPFv3, implementing micro-isolation protection for OSPFv3 packets based on interfaces and destination IP addresses to protect session establishment.

### Context

By default, micro-isolation CAR is enabled for OSPFv3, implementing micro-isolation protection for OSPFv3 packets based on interfaces and destination IP addresses to protect session establishment. When OSPFv3 packets encounter a traffic burst, a large number of OSPFv3 packets may preempt interface bandwidth resources. In the case of an attack, a large number of invalid packets sent to other IP addresses may preempt the bandwidth. Therefore, you are advised not to disable this function.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run **micro-isolation protocol-car ospfv3 { cir cir-value | cbs cbs-value | pir pir-value | pbs pbs-value }\***

Micro-isolation CAR parameters are configured for OSPFv3.

In normal cases, you are advised to use the default values of these parameters. *pir-value* must be greater than or equal to *cir-value*, and *pbs-value* must be greater than or equal to *cbs-value*.

#### Step 3 (Optional) Run **micro-isolation protocol-car ospfv3 disable**

Micro-isolation CAR is disabled for OSPFv3.

By default, micro-isolation CAR for OSPFv3 is enabled. To disable this function, run the **micro-isolation protocol-car ospfv3 disable** command. If this function is disabled, micro-isolation protection is no longer implemented for OSPFv3 packets based on interfaces and destination IP addresses. In normal cases, you are advised to keep micro-isolation CAR enabled for OSPFv3.

#### Step 4 Run commit

The configuration is committed.

----End

### 1.1.5.2.26 Configuring the Threshold Alarm Function for the Number of OSPFv3 Neighbors

If the alarm function is configured for the number of OSPFv3 neighbors and the number of OSPFv3 neighbors exceeds the threshold, an alarm is generated.

#### Context

When the number of established OSPFv3 neighbor relationships exceeds the specifications of the device, establishing more OSPFv3 neighbor relationships may cause the neighbor status to be unstable. To prevent this problem, you can enable the alarm function for the number of OSPFv3 neighbor relationships so that an alarm is generated when the number of OSPFv3 neighbor relationships exceeds the upper alarm threshold.

#### Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **ospfv3 peer alarm-threshold *threshold-value upper-limit upper-value lower-limit lower-value***

The threshold alarm function is configured for the number of OSPFv3 neighbors.

**Step 3** Run **commit**

The configuration is committed.

----End

### 1.1.5.2.27 Maintaining OSPFv3

Maintaining OSPFv3 involves resetting OSPFv3 and clearing OSPFv3 statistics.

#### Clearing OSPFv3 Statistics

This section describes how to clear OSPFv3 statistics, including statistics about OSPFv3 counters and statistics about session-CAR.

#### Context

**NOTICE**

OSPFv3 information cannot be restored after you clear it. Exercise caution when clearing it.

To clear OSPFv3 information, run the following reset commands in the user view.

## Procedure

- Run the **reset ospfv3 { process-id| all } counters [ neighbor [ interface-type interface-number ] [ nbrrouter-id ] ]** command to reset OSPFv3 counters.
- Run the **reset ospfv3 { process-id| all } counters maxage-lsa** command to delete the statistics about router-LSAs that have reached the aging time.
- Run the **reset ospfv3 { process-id| all } frr** command to perform OSPFv3 IP FRR calculation again.
- Run the **reset ospfv3 { process-id| all } peer [ interface-type interface-number ] router-id** command to restart an OSPFv3 neighbor.
- Run the **reset cpu-defend whitelist-v6 session-car ospfv3 statistics slot slot-id** command to clear statistics about whitelist session-CAR for OSPFv3 on a specified interface board.

----End

## Resetting OSPFv3

Restarting OSPFv3 can reset OSPFv3.

## Context

### NOTICE

Resetting an OSPFv3 connection interrupts the OSPFv3 adjacency between devices. Therefore, exercise caution when resetting an OSPFv3 connection.

After modifying the OSPFv3 routing policy or protocol, reset the OSPFv3 connection to validate the modification. To reset OSPFv3 connections, run the following commands as required in the user view.

## Procedure

- Run the **reset ospfv3 { process-id| all } command** to restart the OSPFv3 process.
- Run the **reset ospfv3 { process-id| all } peer [ interface-type interface-number ] router-id** command to restart an OSPFv3 neighbor.
- Run the **reset ospfv3 { process-id| all } redistribution** command to import routes again.

----End

## Disabling OSPFv3 Memory Overload Control

The OSPFv3 memory overload control function is enabled by default. You can disable this function if necessary.

## Context

By default, OSPFv3 memory overload control is enabled. When the system memory is overloaded, each module needs to take necessary measures to control

the memory usage. Upon receiving a memory overload notification from the system, the OSPFv3 module no longer imports new routes and starts to control neighbor relationship establishment based on the memory overload condition to enhance OSPFv3 resilience. In this case, new neighbor relationships cannot be established. For existing neighbor relationships, if they are in the Full state, they will be retained; if they are in a non-Full state, they are not reestablished until the memory recovers from overload.

## Procedure

- Step 1** Run the **system-view** command to enter the system view.
- Step 2** Run the **ospf memory-overload control disable** command to disable OSPFv3 memory overload control.

To reduce the impact of memory overload on services, you are advised not to disable OSPFv3 memory overload control.

- Step 3** Run the **commit** command to commit the configuration.

----End

## Disabling OSPFv3 CPU Overload Control

The OSPFv3 CPU overload control function is enabled by default. You can disable this function if necessary.

## Context

By default, OSPFv3 CPU overload control is enabled. If a device's CPU is overloaded, each module takes necessary measures to control its own CPU usage accordingly. Upon receiving a CPU overload notification from the system, the OSPFv3 module controls the speeds of some internal computing processes and the establishment of neighbor relationships based on the CPU overload condition to enhance the resilience of OSPFv3. In this case, new neighbor relationships cannot be established. For original neighbor relationships, if a neighbor relationship is in the Full state, it will be retained; if a neighbor relationship is in a non-Full state, establishment of the neighbor relationship is paused and can continue only after the CPU recovers from overload.

## Procedure

- Step 1** Run **system-view**

The system view is displayed.

- Step 2** Run **ospf cpu-overload control disable**

OSPFv3 CPU overload control is disabled.

To minimize the impact of CPU overload upon services, you are advised not to disable OSPFv3 CPU overload control.

### Step 3 Run commit

The configuration is committed.

----End

## 1.1.5.2.28 Configuration Examples for OSPFv3

This section provides several OSPFv3 configuration examples.

### Example for Configuring Basic OSPFv3 Functions

This section describes how to configure basic OSPFv3 functions, including enabling OSPF on each router and specifying network segments in different areas.

### Networking Requirements

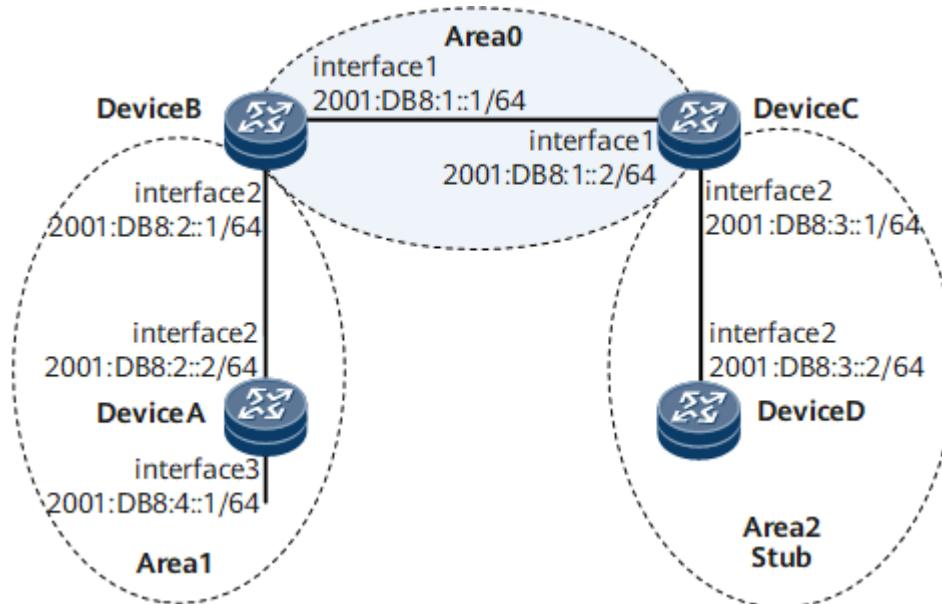

On the network shown in [Figure 1-188](#), all routers run OSPFv3. The entire AS is divided into three areas. DeviceB and DeviceC serve as ABRs to forward inter-area routes.

After the configuration is complete, each router should learn the routes to all network segments in the AS.

**Figure 1-188** Networking for configuring OSPFv3 areas

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

### Configuration Notes

When configuring basic OSPFv3 functions, note the following rules:

- The backbone area is responsible for forwarding inter-area routes. In addition, the routing information between non-backbone areas must be forwarded through the backbone area. OSPFv3 defines the following rules for the backbone area:
  - Connectivity must be available between non-backbone areas and the backbone area.
  - Connectivity must be available over the backbone area.
- The intervals at which Hello, Dead, and Poll packets are sent on the local interface must be the same as those on the remote interface. Otherwise, the OSPFv3 neighbor relationship cannot be established.
- To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication." OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

## Configuration Roadmap

The configuration roadmap is as follows:

1. Enable basic OSPFv3 functions on each router.
2. Specify network segments in different areas.

## Data Preparation

To complete the configuration, you need the following data:

| Device Name | Router ID | Process ID | IPv6 Address                                                   |
|-------------|-----------|------------|----------------------------------------------------------------|
| Device A    | 1.1.1.1   | 1          | Area 1:<br>2001:DB8:4::1/64<br>and<br>2001:DB8:2::2/64         |
| Device B    | 2.2.2.2   | 1          | Area 0:<br>2001:DB8:1::1/64<br><br>Area 1:<br>2001:DB8:2::1/64 |
| Device C    | 3.3.3.3   | 1          | Area 0:<br>2001:DB8:1::2/64<br><br>Area 2:<br>2001:DB8:3::1/64 |
| Device D    | 4.4.4.4   | 1          | Area 2:<br>2001:DB8:3::2/64                                    |

## Procedure

**Step 1** Assign an IPv6 address to each interface. For configuration details, see [Configuration Files](#) in this section.

**Step 2** Configure basic OSPFv3 functions.

# Configure DeviceA.

```
[~DeviceA] ospfv3
[*DeviceA-ospfv3-1] router-id 1.1.1.1
[*DeviceA-ospfv3-1] area 0.0.0.1

Example for Configuring OSPFv3 DR Election

This section describes how to set the DR priority on an interface for DR election on a broadcast network.

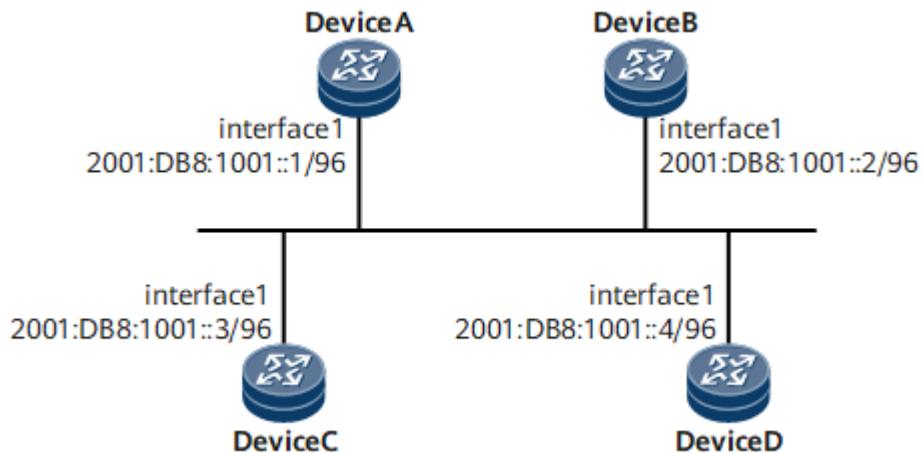

Networking Requirements

On the network shown in [Figure 1-189](#), DeviceA has the highest priority (100) on the network and is elected as the DR; DeviceC has the second highest priority and is elected as the BDR. DeviceB has the priority of 0 and cannot be elected as a DR or a BDR; no priority is configured for DeviceD, and therefore, and DeviceD uses the default value (1).

Figure 1-189 Networking for configuring OSPFv3 DR election

 NOTE

Interface 1 in this example represents GE 1/0/0.

Configuration Notes

Reconfiguring the DR priority for the router does not change the DR or BDR on a network. You can use either of the following methods to re-elect a DR or BDR. However, the following methods will disconnect OSPFv3 adjacencies and therefore are not recommended.

- Restart the OSPFv3 processes on all routers.
- Configure the **shutdown** and **undo shutdown** commands on the interfaces where the OSPFv3 neighbor relationships are established.

To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication". OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

Configuration Roadmap

1. Configure the router ID on each router, enable OSPFv3, and specify the network segment.
2. Check the DR/BDR status with the default priority.
3. Configure the DR priority on the interface and check the DR/BDR status.

Data Preparation

To complete the configuration, you need the following data:

- Router ID (1.1.1.1) and DR priority (100) of Device A
- Router ID (2.2.2.2) and DR priority (0) of Device B
- Router ID (3.3.3.3) and DR priority (2) of Device C
- Router ID (4.4.4.4) and DR priority (1, default value) of Device D

Procedure

Step 1 Assign an IPv6 address to each interface.

For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure basic OSPFv3 functions.

Configure DeviceA, enable OSPFv3, and set its router ID to 1.1.1.1.

```
[*DeviceA] ospfv3
[*DeviceA-ospfv3-1] router-id 1.1.1.1
[*DeviceA-ospfv3-1] quit
[*DeviceA] interface gigabitethernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] ospfv3 1 area 0
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] commit
```

Configure DeviceB, enable OSPFv3, and set its router ID to 2.2.2.2.

```
[*DeviceB] ospfv3
[*DeviceB-ospfv3-1] router-id 2.2.2.2
[*DeviceB-ospfv3-1] quit
[*DeviceB] interface gigabitethernet 1/0/0
[*DeviceB-GigabitEthernet1/0/0] ospfv3 1 area 0
[*DeviceB-GigabitEthernet1/0/0] quit
[*DeviceB] commit
```

Configure DeviceC, enable OSPFv3, and set its router ID to 3.3.3.3.

```
[*DeviceC] ospfv3
[*DeviceC-ospfv3-1] router-id 3.3.3.3
[*DeviceC-ospfv3-1] quit
[*DeviceC] interface gigabitethernet 1/0/0
[*DeviceC-GigabitEthernet1/0/0] ospfv3 1 area 0
[*DeviceC-GigabitEthernet1/0/0] quit
[*DeviceC] commit
```

Configure DeviceD, enable OSPFv3, and set its router ID to 4.4.4.4.

```
[*DeviceD] ospfv3
[*DeviceD-ospfv3-1] router-id 4.4.4.4
[*DeviceD-ospfv3-1] quit
[*DeviceD] interface gigabitethernet 1/0/0
[*DeviceD-GigabitEthernet1/0/0] ospfv3 1 area 0
[*DeviceD-GigabitEthernet1/0/0] quit
[*DeviceD] commit
```

Display the neighbors of DeviceA. You can view the DR priority and the neighbor status. By default, the DR priority is 1. DeviceD is the DR, and DeviceC is the BDR.

NOTE

The router with the greatest router ID is the DR when routers have the same priority. If an Ethernet interface of the router becomes a DR, the other broadcast interfaces of the router have the highest priority in DR election. That is, the DR cannot be preempted.

```
[~DeviceA] display ospfv3 peer
OSPFv3 Process (1)
Total number of peer(s): 3
Peer(s) in full state: 2
OSPFv3 Area (0.0.0.0)
Neighbor ID   Pri  State          Dead Time  Interface  Instance ID
2.2.2.2      1    2-Way/DROther  00:00:32   GE1/0/0      0
3.3.3.3      1    Full/Backup    00:00:36   GE1/0/0      0
4.4.4.4      1    Full/DR       00:00:38   GE1/0/0      0
```

Display the neighbors of DeviceD. The command output shows that all neighbors of DeviceD are in the Full state.

```
[~DeviceD] display ospfv3 peer
OSPFv3 Process (1)
Total number of peer(s): 3
Peer(s) in full state: 3
OSPFv3 Area (0.0.0.0)
Neighbor ID   Pri  State          Dead Time  Interface  Instance ID
1.1.1.1      1    Full/DROther  00:00:32   GE1/0/0      0
2.2.2.2      1    Full/DROther  00:00:35   GE1/0/0      0
3.3.3.3      1    Full/Backup    00:00:30   GE1/0/0      0
```

Step 3 Set the DR priority of the interface.

Set the DR priority of DeviceA to 100.

```
[~DeviceA] interface gigabitethernet 1/0/0
[~DeviceA-GigabitEthernet1/0/0] ospfv3 dr-priority 100
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] commit
```

Set the DR priority of DeviceB to 0.

```
[~DeviceB] interface gigabitethernet 1/0/0
[~DeviceB-GigabitEthernet1/0/0] ospfv3 dr-priority 0
[*DeviceB-GigabitEthernet1/0/0] quit
[*DeviceB] commit
```

Set the DR priority of DeviceC to 2.

```
[~DeviceC] interface gigabitethernet 1/0/0
[~DeviceC-GigabitEthernet1/0/0] ospfv3 dr-priority 2
[*DeviceC-GigabitEthernet1/0/0] quit
[*DeviceC] commit
```

Display the neighbors of DeviceA. The command output shows that the DR priority is updated and that the DR and BDR remain unchanged.

```
[~DeviceA] display ospfv3 peer
OSPFv3 Process (1)
Total number of peer(s): 2
Peer(s) in full state: 3
OSPFv3 Area (0.0.0.0)
Neighbor ID   Pri  State          Dead Time  Interface  Instance ID
2.2.2.2      0    2-Way/DROther  00:00:34   GE1/0/0      0
3.3.3.3      2    Full/Backup    00:00:38   GE1/0/0      0
4.4.4.4      1    Full/DR       00:00:31   GE1/0/0      0
```

Display the neighbors of DeviceD. The command output shows that DeviceD remains the DR.

```
[~DeviceD] display ospfv3 peer
OSPFv3 Process (1)
Total number of peer(s): 3
Peer(s) in full state: 3
OSPFv3 Area (0.0.0.0)
Neighbor ID   Pri  State          Dead Time  Interface  Instance ID
1.1.1.1      100  Full/DROther  00:00:36   GE1/0/0      0
```

2.2.2.2	0	Full/DROther	00:00:30	GE1/0/0	0
3.3.3.3	2	Full/Backup	00:00:36	GE1/0/0	0

Step 4 Re-elect the DR/BDR.

Restart all routers (or run the **shutdown** and **undo shutdown** commands on the interface that establishes the OSPFv3 neighbor relationship), and re-elect the DR/BDR.

Step 5 Verify the configuration.

Display the neighbors of DeviceA. The command output shows that DeviceC is the BDR.

```
[~DeviceA] display ospfv3 peer
OSPFv3 Process (1)
Total number of peer(s): 3
Peer(s) in full state: 3
OSPFv3 Area (0.0.0.0)
Neighbor ID   Pri  State        Dead Time  Interface Instance ID
2.2.2.2       0    Full/DROther  00:00:31   GE1/0/0   0
3.3.3.3       2    Full/Backup   00:00:36   GE1/0/0   0
4.4.4.4       1    Full/DROther  00:00:39   GE1/0/0   0
```

Check the neighbors of DeviceD. The command output shows that DeviceA functions as the DR.

```
[~DeviceD] display ospfv3 peer
OSPFv3 Process (1)
Total number of peer(s): 3
Peer(s) in full state: 2
OSPFv3 Area (0.0.0.0)
Neighbor ID   Pri  State        Dead Time  Interface Instance ID
1.1.1.1       100  Full/DR      00:00:39   GE1/0/0   0
2.2.2.2       0    2-Way/DROther 00:00:35   GE1/0/0   0
3.3.3.3       2    Full/Backup   00:00:39   GE1/0/0   0
```

----End

## Example for Configuring OSPFv3 IP FRR

This section describes the procedure for configuring OSPFv3 IP FRR, including how to block FRR on certain interfaces to prevent the links connected to these interfaces from functioning as backup links and how to bind OSPFv3 IP FRR to a BFD session.

## Networking Requirements

When a fault occurs on the network, OSPFv3 IP FRR rapidly switches traffic to the backup link without waiting for route convergence. This ensures non-stop traffic forwarding.

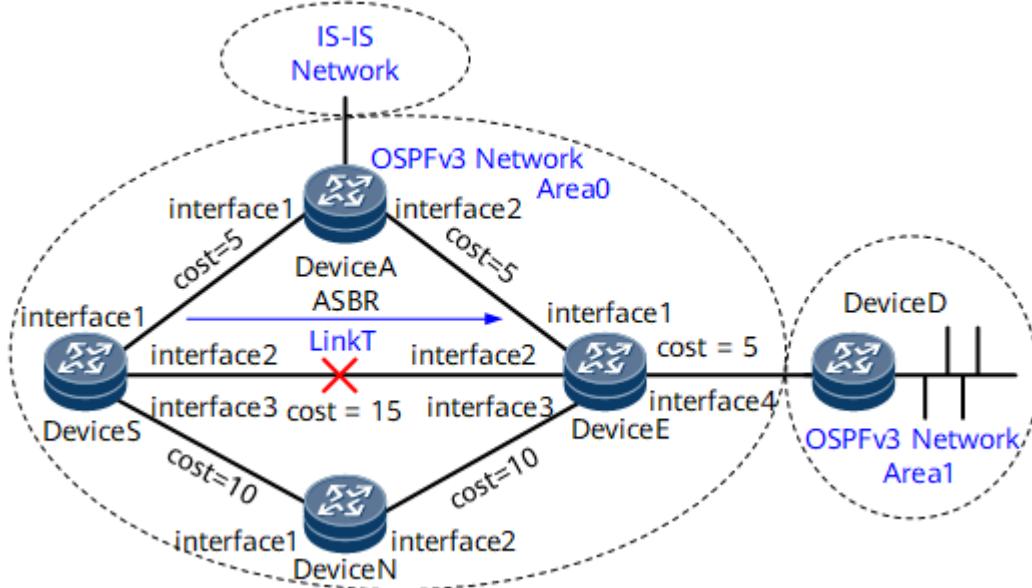

As shown in [Figure 1-190](#):

- OSPFv3 runs on all devices.
- The link cost meets the OSPFv3 IP FRR traffic protection inequality.
- If the primary link T fails, it is required that the traffic from Device S be rapidly redirected to the backup link that passes through Device N.
- Based on the network planning, the link passing through Device A does not function as a backup link.

Figure 1-190 Networking for configuring OSPFv3 IP FRR

 NOTE

Interfaces 1 through 4 in this example represent GE1/0/0, GE2/0/0, GE3/0/0, and GE1/0/1, respectively.

## Configuration Notes

When configuring OSPFv3 IP FRR, note the following points:

- Before configuring OSPFv3 IP FRR, block FRR on certain interfaces to prevent the links connected to these interfaces from functioning as backup links. After that, the link where the interface resides is not calculated as a backup link during FRR calculation.
- When OSPFv3 IP FRR is configured, the underlying layer must be able to quickly respond to link changes so that traffic can be quickly switched to the backup link. After the **bfd all-interfaces frr-binding** command is run, the BFD session status is bound to the link status of the interface (when the BFD session goes down, the link status of the interface also goes down). In this manner, faults can be rapidly detected.
- To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication". OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPFv3 functions on each router. (For configuration details, see [Example for Configuring Basic OSPFv3 Functions](#).)
2. Configure BFD for OSPFv3 on all devices in Area 0.
3. Set the costs of links to ensure that link T is selected to transmit traffic.
4. Block FRR on the specified interface on Device S.

5. Enable OSPFv3 IP FRR on DeviceA to protect the traffic forwarded by DeviceA.

## Data Preparation

To complete the configuration, you need the following data:

| Device   | Router ID | Interface | IPv6 Address        |
|----------|-----------|-----------|---------------------|
| Device S | 1.1.1.1   | GE1/0/0   | 2001:DB8:1000::1/96 |
|          |           | GE2/0/0   | 2001:DB8:1001::1/96 |
|          |           | GE3/0/0   | 2001:DB8:1002::1/96 |
| Device A | 2.2.2.2   | GE1/0/0   | 2001:DB8:1000::2/96 |
|          |           | GE2/0/0   | 2001:DB8:2000::2/96 |
| Device N | 3.3.3.3   | GE1/0/0   | 2001:DB8:1002::2/96 |
|          |           | GE2/0/0   | 2001:DB8:2002::2/96 |
| Device E | 4.4.4.4   | GE1/0/0   | 2001:DB8:2000::1/96 |
|          |           | GE2/0/0   | 2001:DB8:2001::1/96 |
|          |           | GE3/0/0   | 2001:DB8:2002::1/96 |
|          |           | GE1/0/1   | 2001:DB8:3000::1/96 |

## Procedure

- Step 1** Assign an IPv6 address to each interface. For configuration details, see [Configuration Files](#) in this section.
- Step 2** Configure basic OSPFv3 functions. See [Example for Configuring Basic OSPFv3 Functions](#).
- Step 3** Configure BFD for OSPFv3 on all devices in Area 0. See [Example for Configuring BFD for OSPFv3](#).
- Step 4** Set the costs of links to ensure that link T is selected to transmit traffic.

# Configure Device S.

```
[~DeviceS] interface gigabitethernet1/0/0
```

```
[~DeviceS-GigabitEthernet1/0/0] ospfv3 cost 5
[*DeviceS-GigabitEthernet1/0/0] quit

## Example for Configuring BFD for OSPFv3

This section describes how to configure BFD for OSPFv3. After BFD for OSPFv3 is configured, BFD can rapidly detect link faults and report them to OSPFv3 so that service traffic can be transmitted through the backup link.

## Networking Requirements

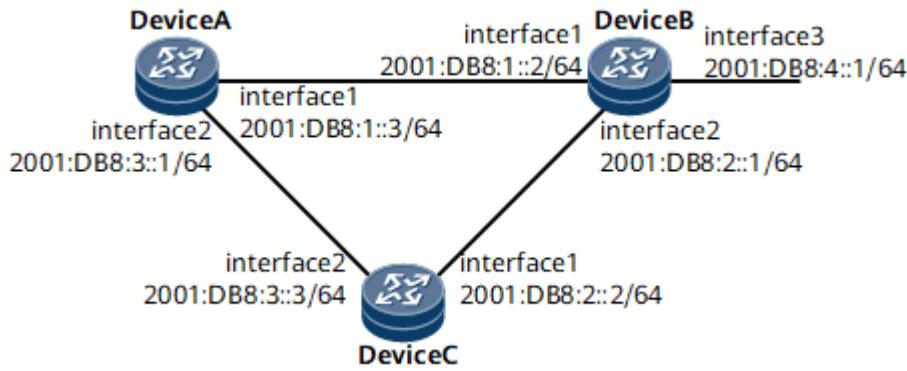

On the network shown in [Figure 1-191](#), the requirements are as follows:

- OSPFv3 runs on Device A, Device B, and Device C.
- BFD is enabled in an OSPFv3 process on Device A, Device B, and Device C.
- Service traffic is transmitted over the primary link (Device A -> Device B). The link (Device A -> Device C -> Device B) functions as the backup link.
- If the link between DeviceA and DeviceB fails, BFD can quickly detect the fault and notify OSPFv3 of the fault so that service traffic can be transmitted through the backup link.

**Figure 1-191** Networking for configuring BFD for OSPFv3

 NOTE

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 1/0/1, and GE 1/0/2, respectively.

## Configuration Notes

To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication". OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPFv3 functions on each router.
2. Configure BFD for OSPFv3.

## Data Preparation

To complete the configuration, you need the following data:

- Router ID of Device A: 1.1.1.1
- Router ID of Device B: 2.2.2.2
- Router ID of Device C: 3.3.3.3
- Minimum interval at which BFD packets are received and sent and local detection multiplier on Device A and Device B

## Procedure

**Step 1** Assign an IPv6 address to each interface. For configuration details, see [Configuration Files](#) in this section.

**Step 2** Configure basic OSPFv3 functions.

# Configure Device A.

```
[*DeviceA] ospfv3
[*DeviceA-ospfv3-1] router-id 1.1.1.1
[*DeviceA-ospfv3-1] quit

Peer(s) in full state: 2
OSPFv3 Area (0.0.0.0)
Neighbor ID Pri State Dead Time Interface Instance ID
2.2.2.2 1 Full/DR 00:00:38 GE1/0/0 0
3.3.3.3 1 Full/- 00:00:37 GE1/0/1 0
```

# View information in the OSPFv3 routing table on Device A. The routing table should contain the routes to Device B and Device C.

```
[~DeviceA] display ospfv3 routing
Codes : E2 - Type 2 External, E1 - Type 1 External, IA - Inter-Area,
 N - NSSA
Flags : A - Added to URT6, LT - Locator Routing
```

| OSPFv3 Process (1)                                                                                                      |        |
|-------------------------------------------------------------------------------------------------------------------------|--------|
| Destination                                                                                                             | Metric |
| 2001:DB8:1::/64<br>directly connected, GE1/0/0, Flags : A                                                               | 1      |
| 2001:DB8:2::/64<br>via FE80::3AE9:7BFF:FE31:307, GE1/0/1, Flags : A<br>via FE80::3AE9:7BFF:FE21:300, GE1/0/0, Flags : A | 2      |
| 2001:DB8:3::/64<br>directly connected, GE1/0/1, Flags : A                                                               | 1      |
| 2001:DB8:4::1/64<br>via FE80::3AE9:7BFF:FE21:300, GE1/0/0                                                               | 1      |

As shown in the OSPFv3 routing table, the next hop address of the route to 2001:DB8:4::1/64 is GigabitEthernet 1/0/0, and traffic is transmitted on the primary link (DeviceA -> DeviceB).

**Step 3** Configure BFD for OSPFv3.

# Enable BFD on Device A globally.

```
[~DeviceA] bfd
[*DeviceA-bfd] quit
[*DeviceA] ospfv3 1

## Example for Configuring IPsec for OSPFv3

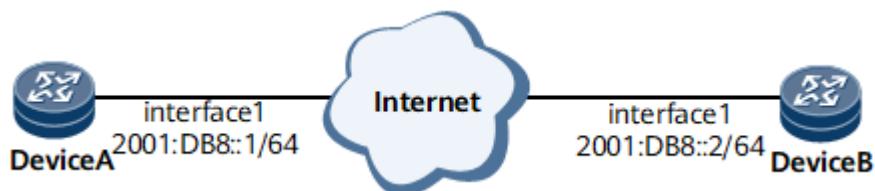

### Networking Requirements

On the network shown in [Figure 1-192](#), DeviceA and DeviceB are connected over a public network, and OSPFv3 is deployed for their communication.

**Figure 1-192** Configuring IPsec

Interface1 in this example represents GE 1/0/1.

If no authentication mechanism is configured, routing protocol packets transmitted between DeviceA and DeviceB may be modified or spoofed by

attackers. As a result, their connection may be torn down, or incorrect routes may be imported.

To prevent such attacks, establish an IPsec tunnel between DeviceA and DeviceB to protect OSPFv3 packets transmitted between them. Configure Encapsulating Security Payload (ESP) as the security protocol, and Secure Hash Algorithm 2-256 (SHA2-256) as the authentication algorithm.

## Configuration Notes

- The encapsulation modes and security protocols on both IPsec peers must be identical.
- The authentication modes and encryption algorithms on the two IPsec peers must be identical.
- The security parameter indexes (SPIs) and authentication keys on the two IPsec peers must be identical.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPFv3 functions on DeviceA and DeviceB.
2. Configure IPsec proposals. Configure ESP as the security protocol, SHA2-256 as the authentication algorithm, and AES-256 as the encryption algorithm.
3. Set SA parameters.
4. Apply SAs to OSPFv3 processes, enabling IPsec to protect OSPFv3 packets transmitted between DeviceA and DeviceB.

## Data Preparation

To complete the configuration, you need the following data:

| Device Name | Router ID | Process ID | SPI   | Authentication Key in String Format |
|-------------|-----------|------------|-------|-------------------------------------|
| DeviceA     | 1.1.1.1   | 1          | 12345 | abcdef                              |
| DeviceB     | 2.2.2.2   | 1          | 12345 | abcdef                              |

## Procedure

### Step 1 Configure OSPFv3 on DeviceA and DeviceB.

# Configure DeviceA.

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceA
[*HUAWEI] commit
[~DeviceA] ospfv3 1
[*DeviceA-ospfv3-1] router-id 1.1.1.1
[*DeviceA-ospfv3-1] area 0
[*DeviceA-ospfv3-1-area-0.0.0.0] commit
```

```
[~DeviceA-ospfv3-1-area-0.0.0] quit
```

```
Configure DeviceB.
```

```
<HUAWEI> system-view
[~HUAWEI] sysname DeviceB
[*HUAWEI] commit
[~DeviceB] ospfv3 1
[*DeviceB-ospfv3-1] router-id 2.2.2.2
[*DeviceB-ospfv3-1] area 0
[*DeviceB-ospfv3-1-area-0.0.0] commit
[~DeviceB-ospfv3-1-area-0.0.0] quit
```

**Step 2** Configure IPv6 addresses for and enable OSPFv3 on interfaces.

```
Configure DeviceA.
```

```
[~DeviceA] interface gigabitethernet1/0/1
[~DeviceA-GigabitEthernet1/0/1] ipv6 enable
[*DeviceA-GigabitEthernet1/0/1] ipv6 address 2001:db8::1 64
[*DeviceA-GigabitEthernet1/0/1] ospfv3 1 area 0
[*DeviceA-GigabitEthernet1/0/1] commit
[~DeviceA-GigabitEthernet1/0/1] quit
```

```
Configure DeviceB.
```

```
[~DeviceB] interface gigabitethernet1/0/1
[~DeviceB-GigabitEthernet1/0/1] ipv6 enable
[*DeviceB-GigabitEthernet1/0/1] ipv6 address 2001:db8::2 64
[*DeviceB-GigabitEthernet1/0/1] ospfv3 1 area 0
[*DeviceB-GigabitEthernet1/0/1] commit
[~DeviceB-GigabitEthernet1/0/1] quit
```

**Step 3** Configure security proposals on DeviceA and DeviceB.

```
Configure a security proposal on DeviceA.
```

```
[~DeviceA] ipsec proposal proposal1
[*DeviceA-ipsec-proposal-proposal1] encapsulation-mode transport
[*DeviceA-ipsec-proposal-proposal1] transform esp
[*DeviceA-ipsec-proposal-proposal1] esp encryption-algorithm aes 256
[*DeviceA-ipsec-proposal-proposal1] esp authentication-algorithm sha2-256
[*DeviceA-ipsec-proposal-proposal1] commit
[~DeviceA-ipsec-proposal-proposal1] quit
```

```
Configure a security proposal on DeviceB.
```

```
[~DeviceB] ipsec proposal proposal2
[*DeviceB-ipsec-proposal-proposal2] encapsulation-mode transport
[*DeviceB-ipsec-proposal-proposal2] transform esp
[*DeviceB-ipsec-proposal-proposal2] esp encryption-algorithm aes 256
[*DeviceB-ipsec-proposal-proposal2] esp authentication-algorithm sha2-256
[*DeviceB-ipsec-proposal-proposal2] commit
[~DeviceB-ipsec-proposal-proposal2] quit
```

```
Run the display ipsec proposal command on DeviceA and DeviceB to check the configuration. The following example uses the command output on DeviceA.
```

```
[~DeviceA] display ipsec proposal
Total IPsec proposal number: 1
IPsec proposal name: proposal1
encapsulation mode: transport
transform: esp-new
ESP protocol: authentication SHA2-HMAC-256, encryption 256-AES
```

**Step 4** Configure IPsec SAs on DeviceA and DeviceB and apply a proposal to each SA.

```
Configure an IPsec SA on DeviceA and apply a proposal to it.
```

```
[~DeviceA] ipsec sa sa1
```

```
[*DeviceA-ipsec-sa-sa1] proposal proposal1
[*DeviceA-ipsec-sa-sa1] commit
```

# Configure an IPsec SA on DeviceB and apply a proposal to it.

```
[~DeviceB] ipsec sa sa2
[*DeviceB-ipsec-sa-sa2] proposal proposal2
[*DeviceB-ipsec-sa-sa2] commit
```

**Step 5** # Configure SPIs and authentication keys in string format on DeviceA and DeviceB.

# Configure SPIs and authentication keys in string format on DeviceA.

```
[~DeviceA] ipsec sa sa1
[*DeviceA-ipsec-sa-sa1] sa spi inbound esp 12345
[*DeviceA-ipsec-sa-sa1] sa spi outbound esp 12345
[*DeviceA-ipsec-sa-sa1] sa string-key inbound esp abcdef
[*DeviceA-ipsec-sa-sa1] sa string-key outbound esp abcdef
[*DeviceA-ipsec-sa-sa1] commit
[~DeviceA-ipsec-sa-sa1] quit
```

# Configure SPIs and authentication keys in string format on DeviceB.

```
[~DeviceB] ipsec sa sa2
[*DeviceB-ipsec-sa-sa2] sa spi outbound esp 12345
[*DeviceB-ipsec-sa-sa2] sa spi inbound esp 12345
[*DeviceB-ipsec-sa-sa2] sa string-key outbound esp abcdef
[*DeviceB-ipsec-sa-sa2] sa string-key inbound esp abcdef
[*DeviceB-ipsec-sa-sa2] commit
[~DeviceB-ipsec-sa-sa2] quit
```

**Step 6** Apply SAs to OSPFv3 processes.

# Apply an SA to an OSPFv3 process on DeviceA.

```
[~DeviceA] ospfv3 1
[*DeviceA-ospfv3-1] ipsec sa sa1
[*DeviceA-ospfv3-1] commit
```

# Apply an SA to an OSPFv3 process on DeviceB.

```
[~DeviceB] ospfv3 1
[*DeviceB-ospfv3-1] ipsec sa sa2
[*DeviceB-ospfv3-1] commit
```

**Step 7** Verify the configuration.

# Run the **display ipsec sa** command on DeviceA and DeviceB to check the configuration. The following example uses the command output on DeviceA.

```
[~DeviceA] display ipsec sa
Total IP security association number: 1
IP security association name: sa1
Number of references: 1
proposal name: proposal1
State: Complete
inbound AH setting:
 AH spi:
 AH string-key:

## Example for Configuring OSPFv3 Route Summarization on an ASBR

This section provides an example showing how to configure OSPFv3 route summarization on an ASBR.

### Networking Requirements

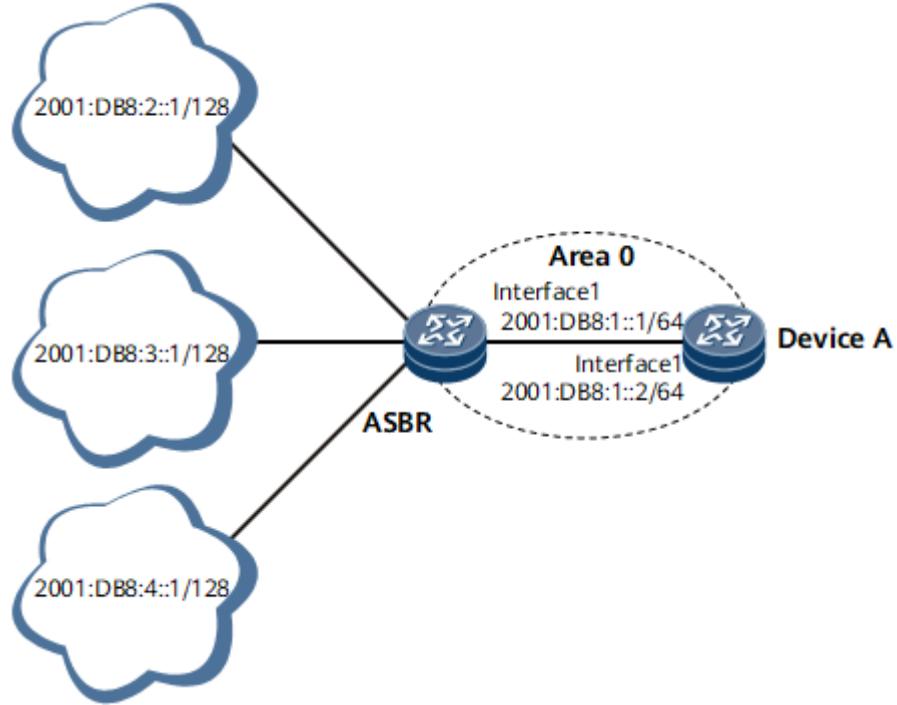

Routes with the same IPv6 prefix can be summarized into one route. On a large-scale OSPFv3 network, route lookup may slow down because of the large size of the routing table. To reduce the routing table size and simplify management, configure route summarization. With route summarization, if a link connected to a device within the IPv6 address range that has been summarized alternates between up and down, the link status change is not advertised to the devices beyond the IPv6 address range. This prevents route flapping and improves network stability.

In [Figure 1-193](#), both the ASBR and Device A run OSPFv3. The ASBR imports three static routes with the same prefix: 2001:DB8:2::1/128, 2001:DB8:3::1/128, and 2001:DB8:4::1/128. After the three static routes with the same prefix are summarized into route 2001:DB8::/32 on the ASBR, the ASBR advertises only this route to area 0. This reduces the size of the routing table, simplifies route management, and improves network stability.

**Figure 1-193** Example for configuring OSPFv3 route summarization on an ASBR

 **NOTE**

Interface 1 in this example represents GE 1/0/0.

## Configuration Notes

To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication". OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

## Configuration Roadmap

The configuration roadmap is as follows:

1. Assign an IP address to each interface to ensure that devices on the network can communicate with each other.
2. Configure basic OSPFv3 functions on the ASBR and Device A.
3. Configure three static routes (2001:DB8:2::1/128, 2001:DB8:3::1/128, and 2001:DB8:4::1/128) on the ASBR and import them into OSPFv3.
4. Configure OSPFv3 route summarization on the ASBR.

## Data Preparation

To complete the configuration, you need the following data:

- Area 0
- Router ID (1.1.1.1) of Device A
- Router ID (2.2.2.2) of the ASBR

## Procedure

**Step 1** Configure an IP address for each interface. For configuration details, see "Configuration Files" in this section.

**Step 2** Configure basic OSPFv3 functions.

# Configure Device A.

```
[~DeviceA] ospfv3 1
[*DeviceA-ospfv3-1] router-id 1.1.1.1
[*DeviceA-ospfv3-1] area 0.0.0.0
[*DeviceA-ospfv3-1-area-0.0.0.0] quit
[*DeviceA-ospfv3-1] quit
[*DeviceA] commit
[~DeviceA] interface gigabitethernet1/0/0
[~DeviceA-GigabitEthernet1/0/0] ospfv3 1 area 0
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] commit
```

# Configure the ASBR.

```
[~ASBR] ospfv3 1
[*ASBR-ospfv3-1] router-id 2.2.2.2
[*ASBR-ospfv3-1] area 0.0.0.0
[*ASBR-ospfv3-1-area-0.0.0.0] quit
[*ASBR-ospfv3-1] quit
[*ASBR] commit
[~ASBR] interface gigabitethernet1/0/0
[~ASBR-GigabitEthernet1/0/0] ospfv3 1 area 0
[*ASBR-GigabitEthernet1/0/0] quit
[*ASBR] commit
```

# After the configuration is complete, run the **display ospfv3 peer** command. The command output shows that a neighbor relationship has been established between DeviceA and the ASBR. The following example uses the command output on the ASBR:

```
[~ASBR] display ospfv3 peer

OSPFv3 Process (1)
Total number of peer(s): 1
Peer(s) in full state: 1
OSPFv3 Area (0.0.0.0)
Neighbor ID Pri State Dead Time Interface Instance ID
1.1.1.1 1 Full/DR 00:00:37 GE1/0/0 0
```

**Step 3** Configure three static routes with the same prefix on the ASBR and import them into OSPFv3.

```
[~ASBR] ipv6 route-static 2001:DB8:2::1 128 NULL0
[*ASBR] ipv6 route-static 2001:DB8:3::1 128 NULL0
[*ASBR] ipv6 route-static 2001:DB8:4::1 128 NULL0
[*ASBR] commit
[~ASBR] ospfv3 1
[*ASBR-ospfv3-1] import-route static
[*ASBR-ospfv3-1] quit
[*ASBR] commit
```

# After the configuration is complete, run the **display ospfv3 lsdb** command on the ASBR to check OSPFv3 LSDB information. There are three AS-external LSAs in the LSDB, and the prefixes of corresponding routes are 2001:DB8:2::/128, 2001:DB8:3::/128, and 2001:DB8:4::/128, indicating that route summarization is not performed.

```
[~ASBR] display ospfv3 lsdb

## Example for Configuring OSPFv3 Route Summarization on an ABR

This section provides an example showing how to configure OSPFv3 route summarization on an ABR.

## Networking Requirements

Routes with the same IPv6 prefix can be summarized into one route. On a large-scale OSPFv3 network, route lookup may slow down because of the large size of the routing table. To reduce the routing table size and simplify management, configure route summarization. With route summarization, if a link connected to a device within an IPv6 address range that has been summarized alternates

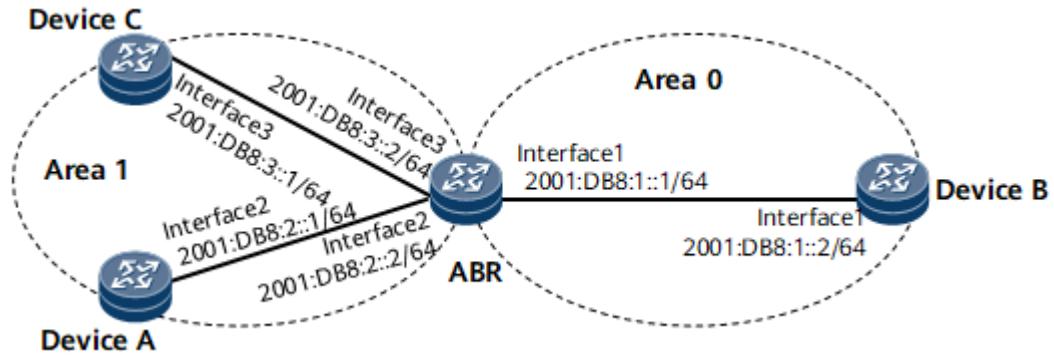

between up and down, the link status change is not advertised to the devices beyond the IPv6 address range. This prevents route flapping and improves network stability.

In [Figure 1-194](#), all devices run OSPFv3. To reduce the routing table size, simplify route management, and improve network stability, it is required that the ABR be configured to summarize area 1's routes with the same prefix (2001:DB8::) into route 2001:DB8::/32 and advertise only the summary route to area 0.

**Figure 1-194** Example for configuring OSPFv3 route summarization on an ABR

 NOTE

Interfaces 1 through 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

## Configuration Notes

To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication". OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

## Configuration Roadmap

The configuration roadmap is as follows:

1. Assign an IP address to each interface to ensure that devices on the network can communicate with each other.
2. Configure basic OSPFv3 functions on all devices.
3. Configure OSPFv3 route summarization on the ABR.

## Data Preparation

To complete the configuration, you need the following data:

- Areas 0 and 1
- Router ID (1.1.1.1) of Device B
- Router ID (2.2.2.2) of the ABR
- Router ID (3.3.3.3) of Device A

- Router ID (4.4.4.4) of Device C

## Procedure

- Step 1** Configure an IP address for each interface. For configuration details, see "Configuration Files" in this section.
- Step 2** Configure basic OSPFv3 functions.

# Configure Device A.

```
[~DeviceA] ospfv3 1

Example for Configuring an OSPFv3 NSSA

This section provides an example for configuring an OSPFv3 not-so-stubby area (NSSA).

Networking Requirements

An excessive number of entries in a routing table waste network resources and cause high CPU usage. To address the problem, configure a non-backbone area on the border of an AS as an NSSA. NSSAs can import AS external routes and advertise them within the entire OSPFv3 AS, without learning external routes from other areas in the AS, which reduces bandwidth and storage resource consumption on the router.

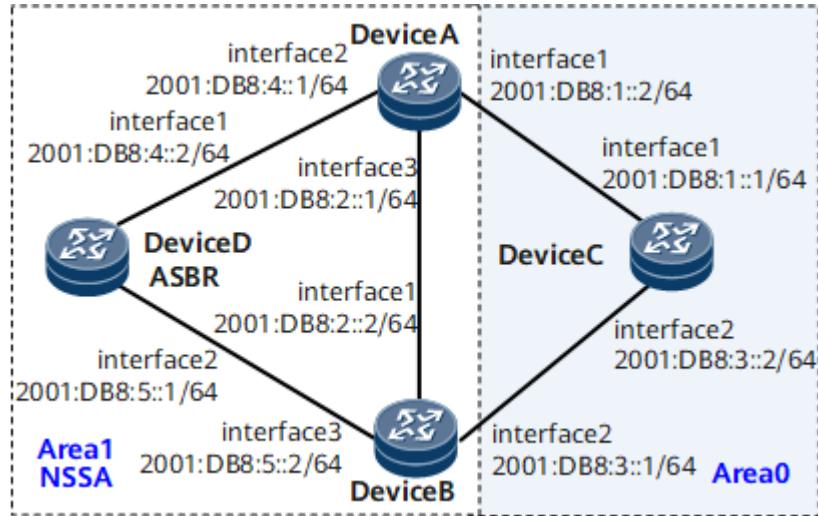

In [Figure 1-195](#), OSPFv3 runs on all routers, and the entire AS is partitioned into two areas. Device A and Device B function as ABRs to forward inter-area routes;

Device D functions as an ASBR and imports the external static route 2001:DB8:6::1/128. To import AS external routes but reduce the number of LSAs to be advertised to area 1 without affecting route reachability, configure area 1 as an NSSA.

Figure 1-195 Networking for configuring an OSPFv3 NSSA

 NOTE

Interfaces 1 through 3 in this example represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

Configuration Notes

To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication". OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic OSPFv3 functions on all routers to ensure that they can communicate with each other using OSPFv3.
2. Configure area 1 as an NSSA.
3. Configure Device C to import the static route 2001:DB8:7::1/128.
4. Configure Device D to import the static route 2001:DB8:6::1/128.

Data Preparation

To complete the configuration, you need the following data:

- Router ID 1.1.1.1 of Device A, OSPFv3 process ID 1, network segment 2001:DB8:1::0/64 of area 0, and network segments 2001:DB8:2::0/64 and 2001:DB8:4::0/64 of area 1

- Router ID 2.2.2.2 of Device B, OSPFv3 process ID 1, network segment 2001:DB8:3::0/64 of area 0, and network segments 2001:DB8:2::0/64 and 2001:DB8:5::0/64 of area 1
- Router ID 3.3.3.3 of Device C, OSPFv3 process ID 1, and network segments 2001:DB8:1::0/64 and 2001:DB8:3::0/64 of area 0
- Router ID 4.4.4.4 of Device D, OSPFv3 process ID 1, and network segments 2001:DB8:4::0/64 and 2001:DB8:5::0/64 of area 1

Procedure

Step 1 Configure an IP address for each interface.

Configure an IP address to each interface according to [Figure 1-195](#). For details about the configuration, see Configuration Files in this section.

Step 2 Configure basic OSPFv3 functions.

For detailed operations, see [Example for Configuring Basic OSPFv3 Functions](#).

Step 3 Configure area 1 as an NSSA.

Configure Device A.

```
[~DeviceA] ospfv3
[*DeviceA-ospfv3-1] area 1
[*DeviceA-ospfv3-1-area-0.0.0.1] nssa
[*DeviceA-ospfv3-1-area-0.0.0.1] commit
[~DeviceA-ospfv3-1-area-0.0.0.1] quit
[~DeviceA-ospfv3-1] quit
```

Configure Device B.

```
[~DeviceB] ospfv3
[*DeviceB-ospfv3-1] area 1
[*DeviceB-ospfv3-1-area-0.0.0.1] nssa
[*DeviceB-ospfv3-1-area-0.0.0.1] commit
[~DeviceB-ospfv3-1-area-0.0.0.1] quit
[~DeviceB-ospfv3-1] quit
```

Configure Device D.

```
[~DeviceD] ospfv3
[*DeviceD-ospfv3-1] area 1
[*DeviceD-ospfv3-1-area-0.0.0.1] nssa
[*DeviceD-ospfv3-1-area-0.0.0.1] commit
[~DeviceD-ospfv3-1-area-0.0.0.1] quit
[~DeviceD-ospfv3-1] quit
```

Step 4 Configure Device C to import the static route 2001:DB8:7::1/128.

```
[~DeviceC] ipv6 route-static 2001:DB8:7::1 128 NULL0
[*DeviceC] ospfv3
[*DeviceC-ospfv3-1] import-route static
[*DeviceC-ospfv3-1] commit
[~DeviceC-ospfv3-1] quit
```

Step 5 Configure Device D to import the static route 2001:DB8:6::1/128.

```
[~DeviceD] ipv6 route-static 2001:DB8:6::1 128 NULL0
[*DeviceD] ospfv3
[*DeviceD-ospfv3-1] import-route static
[*DeviceD-ospfv3-1] commit
[~DeviceD-ospfv3-1] quit
```

Step 6 Verify the configuration.

Display the OSPFv3 routing tables on Device C and Device D.

```
[~DeviceC] display ospfv3 routing
Codes : E2 - Type 2 External, E1 - Type 1 External, IA - Inter-Area,
        N - NSSA
Flags : A - Added to URT6, LT - Locator Routing

OSPFv3 Process (1)
Destination                               Metric

    via FE80::3A6D:7CFF:FE41:1200, Vlanif14, Flags : A
[~DeviceD] display ospfv3 routing
Codes : E2 - Type 2 External, E1 - Type 1 External, IA - Inter-Area,
        N - NSSA
Flags : A - Added to URT6, LT - Locator Routing

OSPFv3 Process (1)
Destination                               Metric
Next-hop
E2 ::/0                                    1
N  via FE80::3A6D:7CFF:FE21:1200, Vlanif13, Flags : A
E2 ::/0                                    1
N  via FE80::3A6D:7CFF:FE41:1200, Vlanif11, Flags : A
IA 2001:DB8:1::/64                         2
    via FE80::3A6D:7CFF:FE21:1200, Vlanif13, Flags : A
2001:DB8:2::/64                           2
    via FE80::3A6D:7CFF:FE21:1200, Vlanif13, Flags : A
2001:DB8:2::/64                           2
    via FE80::3A6D:7CFF:FE41:1200, Vlanif11, Flags : A
IA 2001:DB8:3::/64                         2
    via FE80::3A6D:7CFF:FE41:1200, Vlanif11, Flags : A
2001:DB8:4::/64                           1
    directly connected, Vlanif13, Flags : A
2001:DB8:5::/64                           1
    directly connected, Vlanif11, Flags : A
```

The command output shows that Device C has imported an AS external route (2001:DB8:6::1/128) and that the router that advertises this route is DeviceB. In addition, the NSSA does not learn the 2001:DB8:7::1/128 route from area 0.

Display routing information of the NSSA on routers. In the following example, the command output on Device A is used.

```
[~DeviceA] display ospfv3 routing nssa-routes
Codes : E2 - Type 2 External, E1 - Type 1 External, IA - Inter-Area,
        N - NSSA
Flags : A - Added to URT6

OSPFv3 Process (1)
Destination                               Metric
Next-hop
E2 2001:DB8:6::1/128                     1
N  via FE80::3A6D:7CFF:FE11:1200, Vlanif13, Flags : A
```

Display NSSA LSA information on routers. In the following example, the command output on Device A is used.

```
[~DeviceA] display ospfv3 lsdb nssa
    OSPFv3 Router with ID (1.1.1.1) (Process 1)

Example for Configuring OSPFv3 Delay Reporting to BGP-LS

OSPFv3 delay is reported to BGP-LS, which summarizes the topology information collected by IGPs and sends the information to the upper-layer controller for delay-based path computation.

Networking Requirements

BGP-LS is a new method of collecting network topology information. The topology information discovered by IGPs is summarized and reported to an upper-layer controller through BGP. With powerful routing capabilities of BGP, BGP-LS has the following advantages:

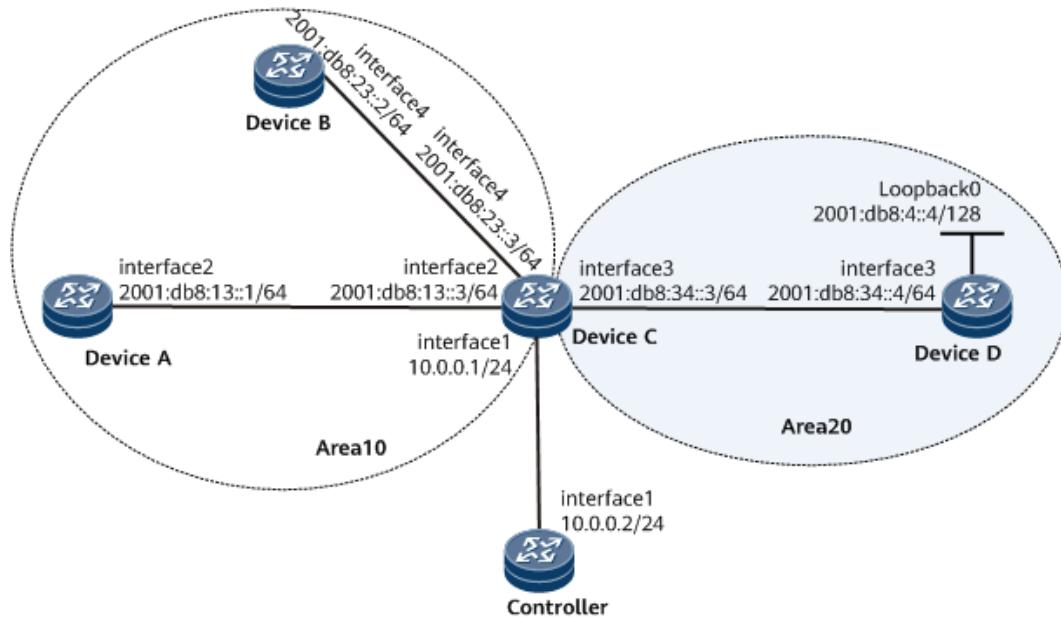

- Lowers the requirements on the controller's computing capabilities and no longer requires IGP capabilities on the controller.
- Facilitates route selection and computation on the controller by using BGP to summarize process or AS topology information and report the complete information to the controller.
- Requires only one routing protocol (BGP) to report topology information to the controller.

In **Figure 1-196**, DeviceC is connected to the controller and reports topology information to the controller. DeviceA, DeviceB, DeviceC, and DeviceD use OSPFv3 to implement IP network interworking. The two interfaces connecting DeviceC and DeviceD belong to area 20, and the interfaces connecting DeviceA, DeviceB, and DeviceC belong to area 10.

Figure 1-196 Configuring BGP-LS

 NOTE

interface1, interface2, interface3, and interface4 in this example represent GigabitEthernet1/0/1, GigabitEthernet1/0/2, GigabitEthernet1/0/3, and GigabitEthernet1/0/4, respectively.

Precautions

To improve security, you are advised to deploy BGP security measures. For details, see "Configuring BGP Security." Keychain authentication is used as an example. For details, see "Example for Configuring BGP Keychain."

Configuration Roadmap

The configuration roadmap is as follows:

1. Configure IPv6 addresses for interfaces on each device.
2. Configure basic OSPFv3 functions.
3. Deploy BGP-LS on DeviceC and the controller.
4. Configure the TWAMP Light Controller and TWAMP Light Responder on DeviceA and DeviceC, respectively.
5. Configure the TE function.
6. Configure delay advertisement on DeviceA.

Data Preparation

To complete the configuration, you need the following data:

- IPv6 addresses and areas of interfaces on DeviceA, DeviceB, DeviceC, and DeviceD
- BGP-LS ID in OSPFv3 on DeviceC
- BGP AS numbers, BGP-LS domain AS numbers, and BGP-LS domain IDs of Device C and the controller

Procedure

Step 1 Assign an IPv6 address to each interface on each device. For configuration details, see [Configuration Files](#) in this section.

Step 2 Configure basic OSPFv3 functions.

Configure DeviceA.

```
[~DeviceA] ospfv3 1
[*DeviceA-ospfv3-1] router-id 1.1.1.1
[*DeviceA-ospfv3-1] area 0.0.0.10
[*DeviceA-ospfv3-1-area-0.0.0.10] quit
[*DeviceA-ospfv3-1] quit
[*DeviceA] interface gigabitethernet 1/0/2
[*DeviceA-GigabitEthernet1/0/2] ospfv3 1 area 0.0.0.10
[*DeviceA-GigabitEthernet1/0/2] ospfv3 network-type p2p
[*DeviceA-GigabitEthernet1/0/2] commit
[~DeviceA-GigabitEthernet1/0/2] quit
```

Configure DeviceB.

```
[~DeviceB] ospfv3 1
[*DeviceB-ospfv3-1] router-id 2.2.2.2
[*DeviceB-ospfv3-1] area 0.0.0.10
[*DeviceB-ospfv3-1-area-0.0.0.10] quit
[*DeviceB-ospfv3-1] quit
[*DeviceB] interface gigabitethernet 1/0/4
[*DeviceB-GigabitEthernet1/0/4] ospfv3 1 area 0.0.0.10
[*DeviceB-GigabitEthernet1/0/4] commit
```

```
[~DeviceB-GigabitEthernet1/0/4] quit
# Configure DeviceC.

[~DeviceC] ospfv3 1
[*DeviceC-ospfv3-1] router-id 3.3.3.3
[*DeviceC-ospfv3-1] area 0.0.0.10
[*DeviceC-ospfv3-1-area-0.0.0.10] quit
[*DeviceC-ospfv3-1] area 0.0.0.20
[*DeviceC-ospfv3-1-area-0.0.0.20] quit
[*DeviceC-ospfv3-1] quit
[*DeviceC] interface gigabitethernet 1/0/2
[*DeviceC-GigabitEthernet1/0/2] ospfv3 1 area 0.0.0.10
[*DeviceC-GigabitEthernet1/0/2] ospfv3 network-type p2p
[*DeviceC-GigabitEthernet1/0/2] quit
[*DeviceC] interface gigabitethernet 1/0/3
[*DeviceC-GigabitEthernet1/0/3] ospfv3 1 area 0.0.0.20
[*DeviceC-GigabitEthernet1/0/3] quit
[*DeviceC] interface gigabitethernet 1/0/4
[*DeviceC-GigabitEthernet1/0/4] ospfv3 1 area 0.0.0.10
[*DeviceC-GigabitEthernet1/0/4] commit
[~DeviceC-GigabitEthernet1/0/4] quit
```

Configure DeviceD.

```
[~DeviceD] ospfv3 1
[*DeviceD-ospfv3-1] router-id 4.4.4.4
[*DeviceD-ospfv3-1] area 0.0.0.20
[*DeviceD-ospfv3-1-area-0.0.0.20] quit
[*DeviceD-ospfv3-1] quit
[*DeviceD] interface gigabitethernet 1/0/3
[*DeviceD-GigabitEthernet1/0/3] ospfv3 1 area 0.0.0.20
[*DeviceD-GigabitEthernet1/0/3] quit
[*DeviceD] interface LoopBack0
[*DeviceD-LoopBack0] ospfv3 1 area 0.0.0.20
[*DeviceD-LoopBack0] commit
[~DeviceD-LoopBack0] quit
```

Step 3 Deploy BGP-LS on DeviceC and the controller.

Enable OSPFv3 topology advertisement on DeviceC.

```
[~DeviceC] ospfv3 1
[*DeviceC-ospfv3-1] bgp-ls enable
[*DeviceC-ospfv3-1] bgp-ls identifier 20
[*DeviceC-ospfv3-1] commit
[~DeviceC-ospfv3-1] quit
```

Enable BGP-LS on DeviceC and establish a BGP-LS peer relationship with the controller.

```
[~DeviceC] bgp 100
[*DeviceC-bgp] peer 10.0.0.2 as-number 100
[*DeviceC-bgp] link-state-family unicast
[*DeviceC-bgp-af-ls] peer 10.0.0.2 enable
[*DeviceC-bgp-af-ls] commit
[~DeviceC-bgp-af-ls] quit
[~DeviceC-bgp] quit
```

Enable BGP-LS on the controller and establish a BGP-LS peer relationship with DeviceC.

```
[~Controller] bgp 100
[*Controller-bgp] peer 10.0.0.1 as-number 100
[*Controller-bgp] link-state-family unicast
[*Controller-bgp-af-ls] peer 10.0.0.1 enable
[*Controller-bgp-af-ls] commit
[~Controller-bgp-af-ls] quit
[~Controller-bgp] quit
```

Step 4 Configure the TWAMP Light Controller and TWAMP Light Responder on DeviceA and DeviceC, respectively.

Configure the TWAMP Light Controller on DeviceA.

```
[~DeviceA] nqa twamp-light
[*DeviceA-twamp-light] client
[*DeviceA-twamp-light-client] test-session 1 sender-ipv6 2001:db8:13::1 reflector-ipv6 2001:db8:13::3
sender-port 862 reflector-port 862
[*DeviceA-twamp-light-client] test-session 1 bind interface GigabitEthernet 1/0/2
[*DeviceA-twamp-light-client] quit
[*DeviceA-twamp-light] sender
[*DeviceA-twamp-light-sender] test start-continual test-session 1 period 1000
[*DeviceA-twamp-light-sender] commit
[~DeviceA-twamp-light-sender] quit
[~DeviceA-twamp-light] quit
```

Configure the TWAMP Light Responder on DeviceC.

```
[~DeviceC] nqa twamp-light
[*DeviceC-twamp-light] responder
[*DeviceC-twamp-light-responder] test-session 1 local-ipv6 2001:db8:13::3 remote-ipv6 2001:db8:13::1
local-port 862 remote-port 862
[*DeviceC-twamp-light-responder] commit
[~DeviceC-twamp-light-responder] quit
[~DeviceC-twamp-light] quit
```

Step 5 Configure TE on DeviceA.

```
[~DeviceA] te attribute enable
[*DeviceA] commit
```

Step 6 Enable TE for the OSPFv3 area on DeviceA.

```
[~DeviceA] ospfv3 1
[*DeviceA-ospfv3-1] area 0.0.0.10
[*DeviceA-ospfv3-1-area-0.0.0.10] traffic-eng enable
[*DeviceA-ospfv3-1-area-0.0.0.10] commit
```

Step 7 Configure delay advertisement on DeviceA.

```
[~DeviceA] ospfv3 1
[*DeviceA-ospf-1] metric-delay advertisement enable
[*DeviceA-ospf-1] commit
```

Step 8 Verify the configuration.

Display information about BGP-LS peers and their status on DeviceC.

```
[~DeviceC] display bgp link-state unicast peer
BGP local router ID : 10.0.0.1
Local AS number : 100

## Example for Configuring Routing Loop Detection for OSPFv3 Multi-Process Mutual Route Import

This section provides an example for configuring routing loop detection for OSPFv3 multi-process mutual route import.

### Networking Requirements

On the live network, routes of an OSPFv3 process can be imported to another OSPFv3 process for redistribution. In such a scenario, routing policies are usually configured on multiple devices to prevent routing loops. If routing policies are incorrectly configured on the devices that import routes, routing loops may occur. To prevent this problem, configure routing loop detection for the routes imported to OSPFv3.

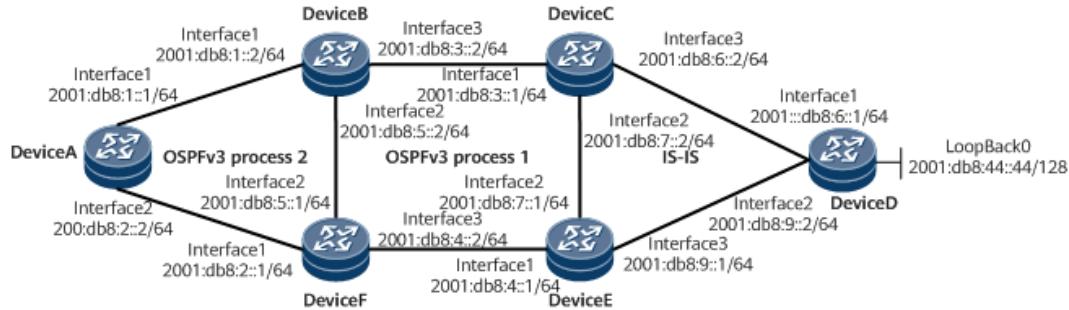

In [Figure 1-197](#), an IS-IS process is configured on DeviceC, DeviceD, and DeviceE. OSPFv3 process 1 is configured on DeviceB, DeviceC, DeviceE, and DeviceF. OSPFv3 process 2 is configured on DeviceA, DeviceB, and DeviceF. DeviceC is configured to import routes from the IS-IS process to OSPFv3 process 1. DeviceB is configured to

import routes from OSPFv3 process 1 to OSPFv3 process 2. DeviceF is configured to import routes from OSPFv3 process 2 to OSPFv3 process 1.

**Figure 1-197** Routing loop detection for OSPFv3 multi-process mutual route import

 **NOTE**

Interfaces 1, 2, and 3 in this example represent GE 1/0/0, GE 2/0/0, and GE 3/0/0, respectively.

## Precautions

To improve security, you are advised to deploy OSPFv3 authentication. For details, see "Configuring OSPFv3 Authentication". OSPFv3 IPSec is used as an example. For details, see "Example for Configuring IPSec for OSPFv3".

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure IP addresses for interfaces on each device.
2. Enable IS-IS and OSPFv3 and configure basic functions.
3. Configure route import to construct a routing loop.
4. Check whether a routing loop occurs.
5. Enable routing loop detection to check whether the routing loop is eliminated.

## Procedure

**Step 1** Assign an IP address to each interface. Take DeviceA as an example.

```
<DeviceA> system-view
[~DeviceA] interface gigabitethernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] ipv6 enable
[*DeviceA-GigabitEthernet1/0/0] ipv6 address 2001:db8:1::1 64
[*DeviceA-GigabitEthernet1/0/0] ipv6 address FE80::A:B link-local
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] interface gigabitethernet 2/0/0
[*DeviceA-GigabitEthernet2/0/0] ipv6 enable
[*DeviceA-GigabitEthernet2/0/0] ipv6 address 2001:db8:2::2 64
[*DeviceA-GigabitEthernet2/0/0] ipv6 address FE80::A:F link-local
[*DeviceA-GigabitEthernet2/0/0] quit
[*DeviceA] commit
```

The configurations of other devices are similar to those of DeviceA. For configuration details, see [Configuration Files](#) in this section.

**Step 2** Enable OSPFv3 and IS-IS, and configure basic OSPFv3 and IS-IS functions to implement intra-area interworking.

# Configure an IS-IS process on DeviceC, DeviceD, and DeviceE. DeviceC is used as an example.

```
[~DeviceC] isis 1
[*DeviceC-isis-1] cost-style wide
[*DeviceC-isis-1] network-entity 10.0000.0000.0003.00
[*DeviceC-isis-1] ipv6 enable topology standard
[*DeviceC-isis-1] quit
[*DeviceC] interface gigabitethernet 2/0/0
[*DeviceC-GigabitEthernet2/0/0] isis ipv6 enable 1
[*DeviceC-GigabitEthernet2/0/0] quit
[*DeviceC] interface gigabitethernet 3/0/0
[*DeviceC-GigabitEthernet3/0/0] isis ipv6 enable 1
[*DeviceC-GigabitEthernet3/0/0] quit
[*DeviceC] commit
```

# Configure OSPFv3 process 1 on DeviceB, DeviceC, DeviceE, and DeviceF. DeviceB is used as an example.

```
[~DeviceB] ospfv3 1
[*DeviceB-ospfv3-1] router-id 2.2.2.1
[*DeviceB-ospfv3-1] area 0
[*DeviceB-ospfv3-1-area-0.0.0] quit
[*DeviceB-ospfv3-1] quit
[*DeviceB] interface gigabitethernet 2/0/0
[*DeviceB-GigabitEthernet2/0/0] ospfv3 1 area 0.0.0.0
[*DeviceB-GigabitEthernet2/0/0] quit
[*DeviceB] interface gigabitethernet 3/0/0
[*DeviceB-GigabitEthernet3/0/0] ospfv3 1 area 0.0.0.0
[*DeviceB-GigabitEthernet3/0/0] quit
[*DeviceB] commit
```

# Configure OSPFv3 process 2 on DeviceA, DeviceB, and DeviceF. DeviceA is used as an example.

```
[~DeviceA] ospfv3 2
[*DeviceA-ospfv3-2] router-id 1.1.1.2
[*DeviceA-ospfv3-2] area 0
[*DeviceA-ospfv3-2-area-0.0.0] quit
[*DeviceA-ospfv3-2] quit
[*DeviceA] interface gigabitethernet 1/0/0
[*DeviceA-GigabitEthernet1/0/0] ospfv3 2 area 0.0.0.0
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] interface gigabitethernet 2/0/0
[*DeviceA-GigabitEthernet2/0/0] ospfv3 2 area 0.0.0.0
[*DeviceA-GigabitEthernet2/0/0] quit
[*DeviceA] commit
```

**Step 3** Configure route import.

# Configure OSPFv3 process 1 on DeviceC and DeviceE to import routes from IS-IS. DeviceC is used as an example.

```
[~DeviceC] ospfv3 1
[*DeviceC-ospfv3-1] router-id 3.3.3.1
[*DeviceC-ospfv3-1] import-route isis 1
[*DeviceC-ospfv3-1] quit
[*DeviceC] commit
```

# Configure OSPFv3 process 2 on DeviceB to import routes from OSPFv3 process 1.

```
[~DeviceB] ospfv3 2
[*DeviceB-ospfv3-2] router-id 2.2.2.2
[*DeviceB-ospfv3-2] import-route ospfv3 1
```

```
[*DeviceB-ospfv3-2] quit
[*DeviceB] commit
```

# Configure OSPFv3 process 1 on DeviceF to import routes from OSPFv3 process 2.

```
[~DeviceF] ospfv3 1
[*DeviceF-ospfv3-1] router-id 6.6.6.1
[*DeviceF-ospfv3-1] import-route ospfv3 2
[*DeviceF-ospfv3-1] quit
[*DeviceF] commit
```

**Step 4** Display the routing table on each device to check whether a routing loop occurs.

# Display OSPFv3 neighbor information on DeviceB.

```
[~DeviceB] display ospfv3 peer
OSPFv3 Process (1)
Total number of peer(s): 2
Peer(s) in full state: 2
OSPFv3 Area (0.0.0.0)
Neighbor ID Pri State Dead Time Interface Instance ID
6.6.6.1 1 Full/DR 00:00:31 GE2/0/0 0
3.3.3.1 1 Full/DR 00:00:36 GE3/0/0 0

OSPFv3 Process (2)
Total number of peer(s): 1
Peer(s) in full state: 1
OSPFv3 Area (0.0.0.0)
Neighbor ID Pri State Dead Time Interface Instance ID
1.1.1.2 1 Full/Backup 00:00:36 GE1/0/0 0
```

The command output shows that OSPFv3 neighbor relationships have been established between devices.

# Display the routing table on DeviceB.

```
[~DeviceB] display ipv6 routing-table 2001:db8:44::44
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Summary Count : 2

Destination : 2001:db8:44::44 PrefixLength : 64
NextHop : FE80::F:B Preference : 150
Cost : 1 Protocol : OSPFv3ASE
RelayNextHop : :: TunnelID : 0x0
Interface : GE2/0/0 Flags : D

Destination : 2001:db8:44::44 PrefixLength : 64
NextHop : FE80::C:B Preference : 150
Cost : 1 Protocol : OSPFv3ASE
RelayNextHop : :: TunnelID : 0x0
Interface : GE3/0/0 Flags : D
```

The preceding routing table on DeviceB shows that one route with the next hop of DeviceF and the other route with the next hop of DeviceC implement load balancing.

# Display the routing table on DeviceA.

```
[~DeviceA] display ipv6 routing-table 2001:db8:44::44
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:44::44 PrefixLength : 64
NextHop : FE80::B:A Preference : 150
Cost : 1 Protocol : OSPFv3ASE
```

```
RelayNextHop : :: TunnelID : 0x0
Interface : GE1/0/0 Flags : D
```

The preceding command output shows that the next hop of the route displayed on DeviceA is DeviceB.

# Display the routing table on DeviceF.

```
[~DeviceF] display ipv6 routing-table 2001:db8:44:44
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Summary Count : 2

Destination : 2001:db8:44::44 PrefixLength : 64
NextHop : FE80::E:F Preference : 150
Cost : 1 Protocol : OSPFv3ASE
RelayNextHop : :: TunnelID : 0x0
Interface : GE3/0/0 Flags : D

Destination : 2001:db8:44::44 PrefixLength : 64
NextHop : FE80::A:F Preference : 150
Cost : 1 Protocol : OSPFv3ASE
RelayNextHop : :: TunnelID : 0x0
Interface : GE1/0/0 Flags : D
```

The preceding routing table on DeviceF shows that one route with the next hop of DeviceA and the other route with the next hop of DeviceE implement load balancing.

This means that a routing loop occurs among DeviceB, DeviceA, and DeviceF.

**Step 5** Enable routing loop detection on each device.

# Enable routing loop detection for routes imported to OSPFv3. DeviceA is used as an example.

```
[~DeviceA] route loop-detect ospfv3 enable
[*DeviceA] commit
```

**Step 6** Check whether the routing loop is eliminated.

# Display the routing table on DeviceB.

```
[~DeviceB] display ipv6 routing-table 2001:db8:44:44
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:44::44 PrefixLength : 64
NextHop : FE80::C:B Preference : 150
Cost : 1 Protocol : OSPFv3ASE
RelayNextHop : :: TunnelID : 0x0
Interface : GE3/0/0 Flags : D
```

The preceding command output shows that the next hop of the route displayed on DeviceB is DeviceC.

# Display the routing table on DeviceA.

```
[~DeviceA] display ipv6 routing-table 2001:db8:44:44
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:44::44 PrefixLength : 64
```

|                     |                      |
|---------------------|----------------------|
| NextHop : FE80::B:A | Preference : 150     |
| Cost : 1            | Protocol : OSPFv3ASE |
| RelayNextHop : ::   | TunnelID : 0x0       |
| Interface : GE1/0/0 | Flags : D            |

The preceding command output shows that the next hop of the route displayed on DeviceA is DeviceB.

# Display the routing table on DeviceF.

```
[~DeviceF] display ipv6 routing-table 2001:db8:44::44
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Summary Count : 1

Destination : 2001:db8:44::44 PrefixLength : 64
NextHop : FE80::E:F Preference : 150
Cost : 1 Protocol : OSPFv3ASE
RelayNextHop : :: TunnelID : 0x0
Interface : GE3/0/0 Flags : D
```

The preceding command output shows that the next hop of the route displayed on DeviceF is DeviceE. This means that the routing loop on DeviceB, DeviceA, and DeviceF is eliminated.

----End

## 1.1.6 RIP Configuration

### 1.1.6.1 RIP Description

#### 1.1.6.1.1 Overview of RIP

##### Definition

Routing Information Protocol (RIP) is a simple Interior Gateway Protocol (IGP). RIP is used in small-scale networks, such as campus networks and simple regional networks.

As a distance-vector routing protocol, RIP exchanges routing information through User Datagram Protocol (UDP) packets with port number 520.

RIP employs the hop count as the metric to measure the distance to the destination. In RIP, by default, the number of hops from the router to its directly connected network is 0; the number of hops from the router to a network that is reachable through another router is 1, and so on. The hop count (the metric) equals the number of routers along the path from the local network to the destination network. To speed up route convergence, RIP defines the hop count as

an integer that ranges from 0 to 15. A hop count that is greater than or equal to 16 is classified as infinite, indicating that the destination network or host is unreachable. Due to the hop limit, RIP is not applicable to large-scale networks.

RIP has two versions:

- RIP version 1 (RIP-1), a classful routing protocol
- RIP version 2 (RIP-2), a classless routing protocol

RIP supports split horizon, poison reverse, and triggered update, which improves the performance and prevents routing loops.

## Purpose

As the earliest IGP, RIP is used in small and medium-sized networks. Its implementation is simple, and the configuration and maintenance of RIP are easier than those of Open Shortest Path First (OSPF) and Intermediate System-to-Intermediate System (IS-IS). Therefore, RIP is widely used on live networks.

### 1.1.6.1.2 Understanding RIP

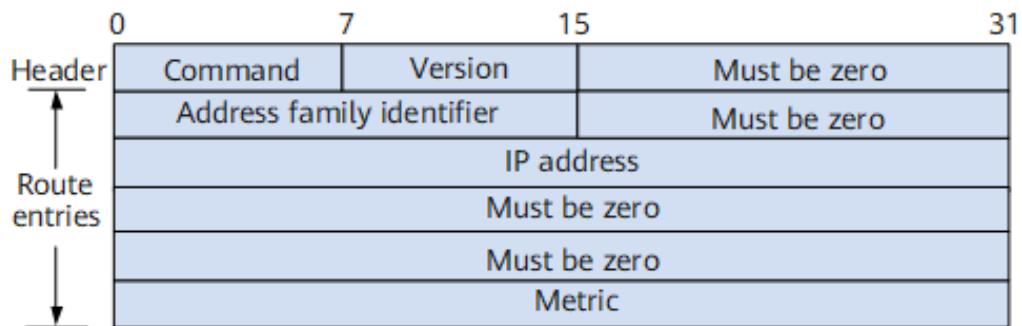

RIP is a distance-vector routing protocol. It forwards packets through UDP and uses timers to control the advertisement, update, and aging of routing information. However, design defects in RIP may cause routing loops. Therefore, split horizon, poison reverse, and triggered update were introduced into RIP to avoid routing loops.

In addition, RIP periodically advertises its routing table to neighbors, and route summarization was introduced to reduce the size of the routing table.

#### RIP-1

RIP version 1 (RIP-1) is a classful routing protocol, which supports only the broadcast of protocol packets. **Figure 1-198** shows the format of a RIP-1 packet. A RIP packet can carry a maximum of 25 routing entries. RIP is based on UDP, and a RIP-1 packet cannot be longer than 512 bytes. RIP-1 packets do not carry any mask information, and RIP-1 can identify only the routes to natural network segments, such as Class A, Class B, and Class C. Therefore, RIP-1 does not support route summarization or discontinuous subnets.

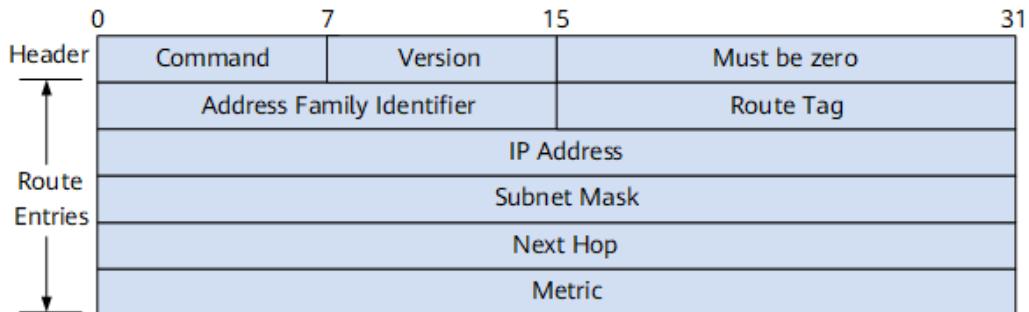

**Figure 1-198** RIP-1 packet format

## RIP-2

RIP version 2 (RIP-2) is a classless routing protocol. [Figure 1-199](#) shows the format of a RIP-2 packet.

**Figure 1-199** RIP-2 packet format

Compared with RIP-1, RIP-2 has the following advantages:

- Supports external route tags and uses a routing policy to flexibly control routes based on the tag.
- Supports route summarization and classless inter-domain routing (CIDR) by adding mask information to RIP-2 packets.
- Supports next hop specification so that the optimal next hop address can be specified on the broadcast network.
- Supports Update packets transmission along multicast routes. Only the routers that support RIP-2 can receive RIP-2 packets, which reduces resource consumption.
- Provides three packet authentication modes: simple text authentication, Message Digest 5 (MD5) authentication and HMAC-SHA256 authentication. For the sake of security, using the HMAC-SHA256 authentication is recommended.

## Timers

RIP uses the following four timers:

- Update timer: The Update timer periodically triggers Update packet transmission. By default, the interval at which Update packets are sent is 30s.
- Age timer: If a device does not receive any packets from its neighbor to update a route before the route expires, the device considers the route unreachable. The default value of the Age timer is 180s.
- Garbage-collect timer: If a route becomes invalid (the Age timer expires or a message indicating that the route is unreachable is received), the route is placed into a garbage queue instead of being immediately deleted from the RIP routing table. The garbage-collect timer is used by the device to monitor the garbage queue and delete expired routes. If a route's Update packet is received before the garbage-collect timer expires, the route is placed back into the age queue. The purpose of setting the garbage-collect timer is to prevent route flapping. The default value of garbage-collect timer is 120s.

- Hold-down timer: If a RIP device receives an updated route with cost 16 from a neighbor, the route enters the hold-down state, and the hold-down timer is started. To prevent route flapping, the RIP device accepts new route updates from the neighbor before the hold-down timer expires only when the following conditions are met:
  - a. The cost carried in the Update packet is less than or equal to that carried in the previous Update packet.
  - b. The hold-down timer expires, and the router enters the garbage-collect state.

The relationship between RIP routes and the four timers is as follows:

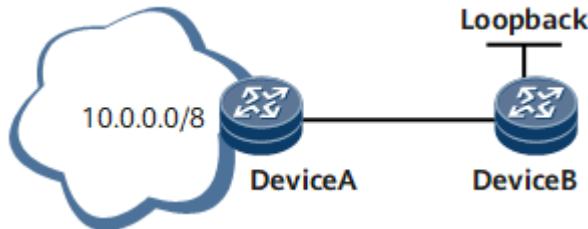

- The advertisement of RIP update information is controlled by the Update timer. By default, RIP update information is sent every 30 seconds.
- Each routing entry is associated with two timers: age timer and garbage-collect timer.
  - a. Whenever a route is learned and added to the routing table, the age timer is started.
  - b. If no Update packet is received from the neighbor within 180 seconds after the age timer is started, the metric of the corresponding route is set to 16, and the garbage-collect timer is started.
- If no Update packet is received within 120 seconds after the garbage-collect timer is started, the corresponding routing entry is deleted from the routing table after the garbage-collect timer expires.
- By default, the hold-down timer of RIP is disabled. If the hold-down timer is enabled manually, it starts after the system receives a route with a cost greater than 16 from a neighbor.

## Split Horizon

### Split Horizon on Broadcast, P2MP, and P2P Networks

Split horizon prevents a RIP-enabled interface from sending back the routes it learns, which reduces bandwidth consumption and prevents routing loops.

**Figure 1-200** Networking for interface-based split horizon

In **Figure 1-200**, Device A sends Device B a route to 10.0.0.0/8. If split horizon is not configured, Device B will send this route back to Device A after learning it from Device A. As a result, Device A learns the following routes to 10.0.0.0/8:

- A direct route with zero hops

- A route with Device B as the next hop and total two hops

Only direct routes, however, are active in the RIP routing table of Device A.

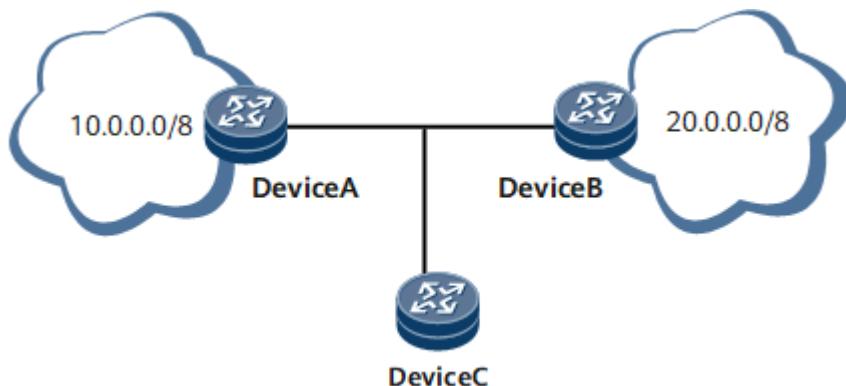

If the route from Device A to 10.0.0.0/8 becomes unreachable and Device B is not notified, Device B still considers the route to 10.0.0.0/8 reachable and continues sending this route to Device A. Then, Device A receives incorrect routing information and considers the route to 10.0.0.0/8 reachable through Device B; Device B considers the route to 10.0.0.0/8 reachable through Device A. As a result, a loop occurs on the network.

After split horizon is configured, Router B no longer sends the route back after learning the route, which prevents such a loop.

## Split Horizon on NBMA Networks

On a Non-Broadcast Multi-Access (NBMA) network where an interface is connected to multiple neighbors, RIP supports neighbor-based split horizon. On NBMA networks, routes are sent in unicast mode, and an interface can differentiate which neighbor each route was learned from, and the interface will not send the routes back to the neighbor it learned them from.

**Figure 1-201** Networking for neighbor-based split horizon on an NBMA network

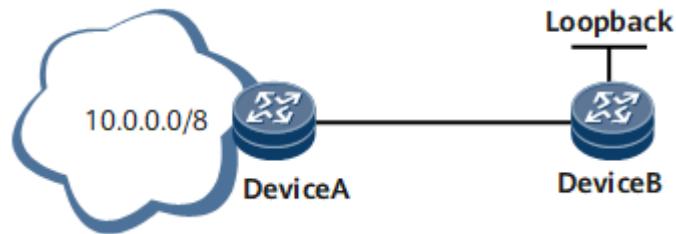

In **Figure 1-201**, Device A sends the route to 10.0.0.0/8 that it learns from Device B only to Device C.

## Poison Reverse

Poison reverse allows a RIP-enabled interface to set the cost of the route that it learns from a neighbor to 16 (indicating that the route is unreachable) and then send the route back. After receiving this route, the neighbor deletes the useless route from its routing table, which prevents loops.

Figure 1-202 Networking for poison reverse

In **Figure 1-202**, Device A sends Device B a route to 10.0.0.0/8. If poison reverse is not configured, Device B will send this route back to Device A after learning it from Device A. As a result, Device A learns the following routes to 10.0.0.0/8:

- A direct route with zero hops
- A route with Device B as the next hop and total two hops

Only direct routes, however, are active in the RIP routing table of Device A.

If the route from Device A to 10.0.0.0 becomes unreachable and Device B is not notified, Device B still considers the route to 10.0.0.0/8 reachable and continues sending this route to Device A. Then, Device A receives incorrect routing information and considers the route to 10.0.0.0/8 reachable through Device B; Device B considers the route to 10.0.0.0/8 reachable through Device A. As a result, a loop occurs on the network.

With poison reverse, after Device B receives the route from Device A, Device B sends a route unreachable message to Device A with cost 16. Device A then no longer learns the reachable route from Device B, which prevents routing loops.

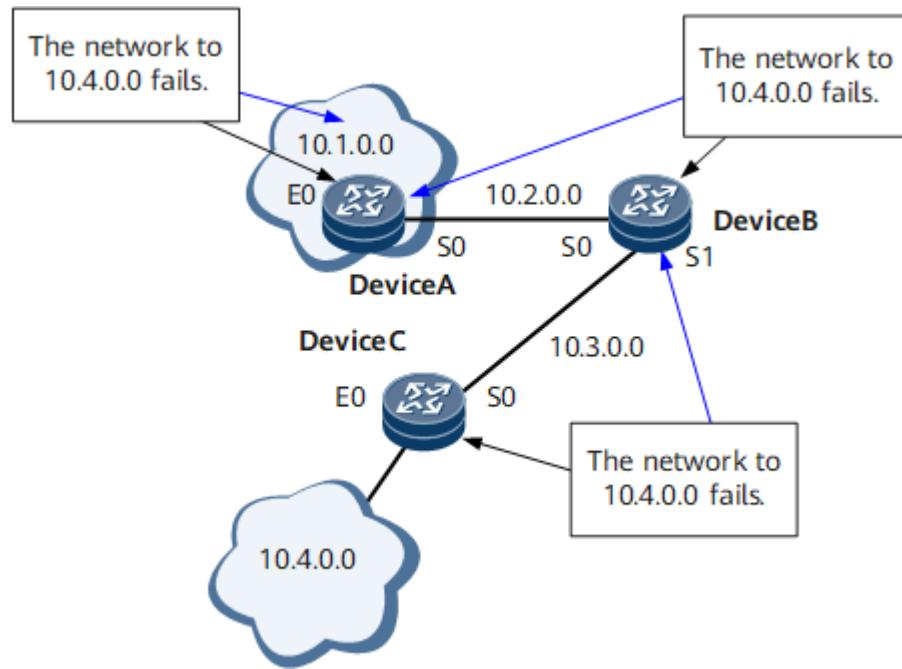

If both split horizon and poison reverse are configured, only poison reverse takes effect.

## Triggered Update

The principle of triggered update is that when the routing information changes, it immediately sends a triggered update message to its neighbor to notify the changed routing information.

Triggered update allows a device to advertise routing information changes immediately, which speeds up network convergence.

Figure 1-203 Networking for triggered update

In **Figure 1-203**, if the route to 10.4.0.0 becomes unreachable, Device C learns the information first. By default, a RIP-enabled device sends routing updates to its neighbors every 30s. If Device C receives an Update packet from Device B within 30s while Device C is still waiting to send Update packets, Device C learns the incorrect route to 10.4.0.0. In this case, the next hops of the routes from Device B or Device C to network 10.4.0.0 are Device C and Device B respectively, which results in routing loops. If Device C sends an Update packet to Device B immediately after it detects a network, Device B can rapidly update its routing table, which prevents routing loops.

In addition, if the next hop of a route becomes unavailable due to a link failure, the local Device sets the cost of the route to 16 and then advertises the route immediately to its neighbors. This process is called route poisoning.

## Route Summarization

Route summarization allows routes to the same natural network segment but different subnets to be summarized into a single route belonging to the same network segment before it is transmitted to other network segments. RIP-1 packets do not carry mask information, and therefore RIP-1 can advertise only routes with natural masks. RIP-2 supports route summarization because RIP-2 packets carry mask information. Therefore, RIP-2 supports subnetting.

In RIP-2, route summarization can reduce the size of the routing table and improve the extensibility and efficiency of a large-scale network.

Route summarization has two modes:

- Process-based classful summarization

Summary routes are advertised with natural masks. If split horizon or poison reverse is configured, classful summarization becomes invalid because split

horizon or poison reverse suppresses some routes from being advertised. In addition, when classful summarization is configured, routes learned from different interfaces may be summarized into a single route. As a result, a conflict occurs in the advertisement of the summary route.

For example, a RIP process summarizes the route 10.1.1.0 /24 with metric 2 and route 10.2.2.0/24 with metric 3 into the route 10.0.0.0/8 with metric 2.

- Interface-based summarization

Users can specify a summary address.

For example, users can configure a RIP-enabled interface to summarize the route 10.1.1.0/24 with metric 2 and route 10.1.2.0/24 with metric 3 into the route 10.1.0.0/16 with metric 2.

## Multi-Process and Multi-Instance

RIP supports multi-process and multi-instance to simplify network management and improve service control efficiency. Multi-process allows a set of interfaces to be associated with a specific RIP process, which ensures that the specific RIP process performs all the protocol operations only on this set of interfaces. Therefore, multiple RIP processes can run on one router, and each process manages a unique set of interfaces. In addition, the routing data of each RIP process is independent; however, processes can import routes from each other.

On routers that support VPN, each RIP process is associated with a specific VPN instance. Therefore, all the interfaces associated with the RIP process need to be associated with the RIP process-related VPN instance.

## BFD for RIP

### Background

Routing Information Protocol (RIP)-capable devices monitor the neighbor status by exchanging Update packets periodically. During the period local devices detect link failures, carriers or users may lose a large number of packets. Bidirectional forwarding detection (BFD) for RIP can speed up fault detection and route convergence, which improves network reliability.

After BFD for RIP is configured on the router, BFD can detect a fault (if any) within milliseconds and notify the RIP module of the fault. The router then deletes the route that passes through the faulty link and switches traffic to a backup link. This process speeds up RIP convergence.

**Table 1-79** describes the differences before and after BFD for RIP is configured.

**Table 1-79** Differences before and after BFD for RIP is configured

| Item                           | Link Fault Detection Mechanism | Convergence Speed |
|--------------------------------|--------------------------------|-------------------|
| BFD for RIP is not configured. | A RIP aging timer expires.     | Second-level      |

| Item                       | Link Fault Detection Mechanism | Convergence Speed |
|----------------------------|--------------------------------|-------------------|
| BFD for RIP is configured. | A BFD session goes Down.       | Millisecond-level |

## Related Concepts

The BFD mechanism bidirectionally monitors data protocol connectivity over the link between two routers. After BFD is associated with a routing protocol, BFD can rapidly detect a fault (if any) and notify the protocol module of the fault, which speeds up route convergence and minimizes traffic loss.

BFD is classified into the following modes:

- Static BFD

In static BFD mode, BFD session parameters (including local and remote discriminators) must be configured, and requests must be delivered manually to establish BFD sessions.

Static BFD is applicable to networks on which only a few links require high reliability.

- Dynamic BFD

In dynamic BFD mode, the establishment of BFD sessions is triggered by routing protocols, and the local discriminator is dynamically allocated, whereas the remote discriminator is obtained from BFD packets sent by the neighbor.

When a new neighbor relationship is set up, a BFD session is established based on the neighbor and detection parameters, including source and destination IP addresses. When a fault occurs on the link, the routing protocol associated with BFD can detect the BFD session Down event. Traffic is switched to the backup link immediately, which minimizes data loss.

Dynamic BFD is applicable to networks that require high reliability.

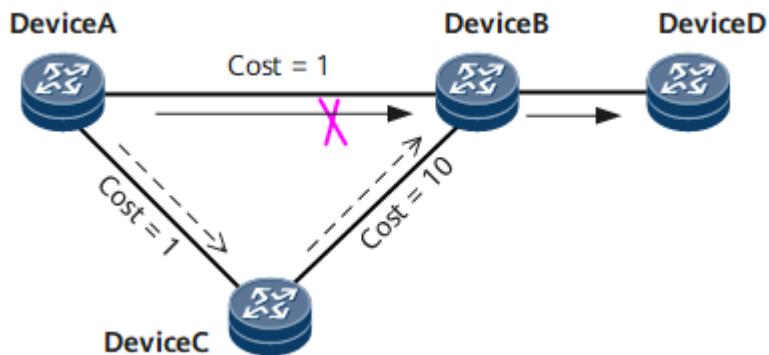

## Implementation

For details about BFD implementation, see "BFD" in *Router Feature Description - Reliability*. [Figure 1-204](#) shows a typical network topology for BFD for RIP.

- Dynamic BFD for RIP implementation:
  - a. RIP neighbor relationships are established among Device A, Device B, and Device C and between Device B and Device D.
  - b. BFD for RIP is enabled on Device A and Device B.
  - c. Device A calculates routes, and the next hop along the route from Device A to Device D is Device B.
  - d. If a fault occurs on the link between Device A and Device B, BFD will rapidly detect the fault and report it to Device A. Device A then deletes the route whose next hop is Device B from the routing table.
  - e. Device A recalculates routes and selects a new path Device C → Device B → Device D.

- f. After the link between Device A and Device B recovers, a new BFD session is established between the two routers. Device A then reselects an optimal link to forward packets.
- Static BFD for RIP implementation:
  - a. RIP neighbor relationships are established among Device A, Device B, and Device C and between Device B and Device D.
  - b. Static BFD is configured on the interface that connects Device A to Device B.
  - c. If a fault occurs on the link between Device A and Device B, BFD will rapidly detect the fault and report it to Device A. Device A then deletes the route whose next hop is Device B from the routing table.
  - d. After the link between Device A and Device B recovers, a new BFD session is established between the two routers. Device A then reselects an optimal link to forward packets.

**Figure 1-204 BFD for RIP**

## Usage Scenario

BFD for RIP is applicable to networks that require high reliability.

## Benefits

BFD for RIP improves network reliability and enables devices to rapidly detect link faults, which speeds up route convergence on RIP networks.

## RIP NSR

Devices with a distributed architecture support RIP Non-stop Routing (NSR). RIP backs up all route data from the Active Main Board (AMB) to the Standby Main Board (SMB). Whenever the AMB fails, the SMB becomes active and takes over traffic. RIP NSR ensures that routes are synchronous between the AMB and SMB. Therefore, during the AMB/SMB switchover, the neighbor will not detect the fault on the local device.

## RIP Authentication

As networks develop, there has been considerable growth in all types of data, voice, and video information exchanged on networks. In addition, new services, such as E-commerce, online conferencing and auctions, video on demand (VoD),

and e-learning have sprung up increasingly, requiring higher information security than before. Carriers must protect data packets from being illegally obtained or modified by attackers and prohibit unauthorized users from accessing network resources. RIP packet authentication effectively meets these security requirements.

RIP authentication falls into the following modes:

- Simple authentication: The authenticated party adds the configured password directly to packets for authentication. This authentication mode provides the lowest password security.
- MD5 authentication: The authenticated party uses the Message Digest 5 (MD5) algorithm to generate a ciphertext password and adds it to packets for authentication. This authentication mode improves password security. For the sake of security, using the HMAC-SHA256 algorithm rather than the MD5 algorithm is recommended.
- Keychain authentication: The authenticated party configures a keychain that changes over time. This authentication mode further improves password security.

Keychain authentication improves RIP security by periodically changing the password and the encryption algorithms. For details about Keychain, see "Keychain" in NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X Feature Description - Security.

- HMAC-SHA256 authentication: The authenticated party uses the HMAC-SHA256 algorithm to generate a ciphertext password and adds it to packets for authentication.

RIP authentication ensures network security by adding an authentication field used to encrypt a packet before sending the packet to ensure network security. After receiving a RIP packet from a remote router, the local router discards the packet if the authentication password in the packet does not match the local authentication password. This authentication mode protects the local router.

On IP networks of carriers, RIP authentication ensures the secure transmission of packets, improves the system security, and provides secure network services for carriers.

### 1.1.6.2 RIP Configuration

RIP can advertise and receive routes to select routes for data forwarding and provide the Network Management Station (NMS) function. RIP is applicable to small-scale networks.

#### 1.1.6.2.1 Overview of RIP

RIP protocol can implement the interworking of small and medium-sized networks.

#### Definition

Routing Information Protocol (RIP) is a simple Interior Gateway Protocol (IGP). RIP is used in small-scale networks, such as campus networks and simple regional networks.

As a distance-vector routing protocol, RIP exchanges routing information through User Datagram Protocol (UDP) packets with port number 520.

RIP employs the hop count as the metric to measure the distance to the destination. In RIP, by default, the number of hops from the router to its directly connected network is 0; the number of hops from the router to a network that is reachable through another router is 1, and so on. The hop count (the metric) equals the number of routers along the path from the local network to the destination network. To speed up route convergence, RIP defines the hop count as an integer that ranges from 0 to 15. A hop count that is greater than or equal to 16 is classified as infinite, indicating that the destination network or host is unreachable. Due to the hop limit, RIP is not applicable to large-scale networks.

RIP has two versions:

- RIP version 1 (RIP-1), a classful routing protocol
- RIP version 2 (RIP-2), a classless routing protocol

RIP supports split horizon, poison reverse, and triggered update, which improves the performance and prevents routing loops.

## Purpose

As the earliest IGP, RIP is used in small and medium-sized networks. Its implementation is simple, and the configuration and maintenance of RIP are easier than those of Open Shortest Path First (OSPF) and Intermediate System-to-Intermediate System (IS-IS). Therefore, RIP is widely used on live networks.

### 1.1.6.2.2 Configuration Precautions for RIP

## Feature Requirements

**Table 1-80** Feature requirements

| Feature Requirements                                                                                                                                                                                                                                                                                                                                 | Series           | Models                                                                                     |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|--------------------------------------------------------------------------------------------|
| After the device is restarted, if the BFD session status of the local device or neighbor is AdminDown, the RIP status is not affected. When the BFD session is renegotiated, if BFD reports the detection status Down but the previous detection status is Up, RIP sets the neighbor status to Down. In other cases, the RIP status is not affected. | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X |

### 1.1.6.2.3 Configuring Basic RIP Functions

To use RIP features, start RIP and specify the network segment and RIP version first.

## Usage Scenario

Configuring basic RIP functions is a prerequisite for building RIP networks.

## Pre-configuration Tasks

Before configuring basic RIP functions, complete the following tasks:

- Configure the link layer protocol.
- Configure network layer addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.

## Creating a RIP process

The creation of a RIP process is a precondition of all RIP configurations.

## Usage Scenario

Before running RIP on a device, you need to create a RIP process on the device.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

RIP supports multi-instance. To bind a RIP process to a VPN instance, you can run the **rip [ process-id ] vpn-instance vpn-instance-name** command.

### Step 3 (Optional) Run **description description**

A description is configured for the RIP process.

### Step 4 Run **commit**

The configuration is committed.

----End

## Follow-up Procedure

If you run RIP-related commands in the interface view before enabling RIP, the configurations take effect only after RIP is enabled.

## Enabling RIP on Specified Network Segments

To enable a RIP process to receive and send RIP routes on specified network segments, enable RIP for the network segments first.

## Context

You can perform either of the following operations to enable RIP on specified network segments:

- Run the **network** command in the RIP process view to enable a RIP process to receive and send routes on a specified network segment.

- Run the **rip enable** command in the interface view to enable a RIP process to receive and send routes on all the network segments where a specified interface is located.

 **NOTE**

The **rip enable** command takes precedence over the **network** command.

## Procedure

- Enable a RIP process to receive and send routes on a specified network segment.
  - Run **system-view**  
The system view is displayed.
  - Run **rip [ process-id ]**  
A RIP process is created, and the view of the RIP process is displayed.
  - Run **network network-address**  
RIP is enabled on a specified network segment.
  - Run **commit**  
The configuration is committed.  
RIP runs only on interfaces on the specified network segment.
- Enable a RIP process to receive and send routes on all specified network segments where a specified interface is located.
  - Run **system-view**  
The system view is displayed.
  - Run **interface interface-type interface-number**  
The interface view is displayed.
  - Run **rip enable process-id**  
RIP is enabled on all the network segments where the interface is located.
  - Run **commit**  
The configuration is committed.

----End

## (Optional) Configuring the RIP Version Number

RIP include RIP-1 and RIP-2. The two versions have different functions.

## Procedure

- Configure the global RIP version number.
  - Run **system-view**  
The system view is displayed.
  - Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

- c. Run **version** *version-num*

The global RIP version number is specified.

 NOTE

The RIP-1 protocol poses a security risk, and therefore the RIP-2 protocol is recommended.

- d. Run **commit**

The configuration is committed.

- Configure the RIP version number on an interface.

- a. Run **system-view**

The system view is displayed.

- b. Run **interface** *interface-type interface-number*

The interface view is displayed.

- c. Run **rip version** { 1 | 2 [ **broadcast** | **multicast** ] }

The RIP version number is specified for the interface.

 NOTE

The RIP-1 protocol poses a security risk, and therefore the RIP-2 protocol is recommended.

- d. Run **commit**

The configuration is committed.

----End

## (Optional) Configuring a RIP Preference

When there are routes discovered by multiple routing protocols on the same device, you can set a preference for RIP to control the route selection result.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **rip** [ *process-id* ]

A RIP process is created, and the RIP view is displayed.

#### Step 3 Run **preference** { *preference* | { **route-policy** *route-policy-name* | **route-filter** *route-filter-name* } } \*

A preference is set for RIP.

The **preference** command can be used together with a route-policy to set a preference for the matched routes.

If the RIP preference is changed after RIP routing information is delivered to the routing management (RM) module, the RM module re-updates the routing table.

#### Step 4 Run commit

The configuration is committed.

----End

### (Optional) Disabling Check on the Source Address of RIP Packets on a P2P Network

On a P2P network, IP addresses of interfaces at the two ends of a link may belong to different networks. Therefore, the two ends can receive packets from each other only when the check on the source addresses of RIP packets is disabled.

#### Context

By default, RIP checks the source addresses of received packets, and the local RIP interface receives only the packets from the same network. On a P2P network, IP addresses of interfaces at the two ends of a link may belong to different networks. Therefore, the two ends can receive packets from each other only when the check on the source addresses of RIP packets is disabled.

#### Procedure

##### Step 1 Run system-view

The system view is displayed.

##### Step 2 Run rip [*process-id*]

A RIP process is created, and the RIP view is displayed.

##### Step 3 Run undo verify-source

The check on the source address of RIP packets is disabled.

##### Step 4 Run commit

The configuration is committed.

----End

### (Optional) Enabling Check on Zero Fields of RIP-1 Packets

Certain fields in RIP-1 packets must be 0, and these fields are called zero fields.

#### Context

Certain fields in RIP-1 packets must be 0, and RIP-2 packets contain no zero fields.

#### Procedure

##### Step 1 Run system-view

The system view is displayed.

##### Step 2 Run rip [*process-id*]

A RIP process is created, and the RIP view is displayed.

### Step 3 Run **checkzero**

The check on zero fields of RIP-1 packets is configured.

### Step 4 Run **commit**

The configuration is committed.

----End

## Configuring an NBMA Network

RIP packets on a Non-Broadcast Multiple Access (NBMA) network are sent in a mode different from those on networks of other types, and therefore, special configurations are required.

## Usage Scenario

RIP packets are sent in unicast mode only on an NBMA network. On networks of other types, RIP packets are sent in either broadcast or multicast mode.

Therefore, you need to perform the following configurations for an NBMA network:

- Specify RIP neighbors.
- Prevent interfaces from sending RIP packets in either broadcast or multicast mode.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

### Step 3 Run **peer peer-address**

RIP neighbors are configured on the NBMA network.

### Step 4 Perform either of the following operations as required:

- Run the **silent-interface all** command to prevent all interfaces from sending RIP packets in either broadcast or multicast mode.
- Run the **silent-interface interface-type interface-number** command to prevent a specified interface from sending RIP packets in either broadcast or multicast mode.

#### NOTE

If you want a small number of interfaces to send RIP packets in either broadcast or multicast mode, you can run the **silent-interface all** command first to prevent all interfaces from sending RIP packets in either broadcast or multicast mode and then run the **silent-interface disable interface-type interface-number** command to restore the capability to send RIP packets in either broadcast or multicast mode for the small number of interfaces.

### Step 5 Run commit

The configuration is committed.

----End

## Verifying the Configuration

After basic RIP functions are configured, you can view the current running status of RIP and RIP routing information.

## Prerequisites

All the basic RIP functions have been configured.

## Procedure

- Run the **display rip [ process-id | vpn-instance vpn-instance-name ]** command to check RIP running status and configuration.
- Run the **display rip process-id route** command to check RIP routes.

----End

### 1.1.6.2.4 Preventing Routing Loops

RIP is based on the DV algorithm. RIP devices advertise their routing tables to their neighbors, and therefore, routing loops may occur.

## Usage Scenario

RIP prevents routing loops through the following mechanisms:

- Counting to infinity: RIP defines the cost 16 as infinity. If the cost of a route reaches 16 due to a routing loop, this route is considered unreachable.
- Split horizon: Split horizon prevents a RIP-enabled interface from sending back the routes it learns, which reduces bandwidth consumption and prevents routing loops.
- Poison reverse: Poison reverse allows a RIP-enabled interface to set the cost of the route that it learns from a neighbor to 16 (indicating that the route is unreachable) and then send the route back. After receiving this route, the neighbor deletes the useless route from its routing table, which prevents loops.
- Suppression timers: Suppression timers can prevent routing loops and reduce the possibility of resulting in incorrect routing information due to the receiving of incorrect routes.
- Disabling an interface from receiving and sending RIP packets: Similar to split horizon or poison reverse, this function filters out unreliable IP routes. However, routing information on the network may be incorrect because neighbors cannot receive packets from the local router.

#### NOTE

Counting to infinity is a basic feature of RIP, and therefore, it does not need to be configured. Split horizon and poison reverse, however, need to be configured. When both split horizon and poison reverse are configured, only poison reverse takes effect.

## Pre-configuration Tasks

Before configuring RIP to prevent routing loops on the network, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.6.2.3 Configuring Basic RIP Functions](#)

## Configuration Procedure

Perform one or more of the following configurations as required.

### Configuring Split Horizon

You can configure split horizon to prevent routing loops.

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

##### Step 3 Run **rip split-horizon**

Split horizon is enabled.

##### Step 4 Run **commit**

The configuration is committed.

----End

#### Follow-up Procedure

If both split horizon and poison reverse are configured, only poison reverse takes effect.

### Configuring Poison Reverse

You can configure poison reverse to prevent routing loops.

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

##### Step 3 Run **rip poison-reverse**

Poison reverse is enabled.

#### Step 4 Run commit

The configuration is committed.

----End

### Follow-up Procedure

If both split horizon and poison reverse are configured, only poison reverse takes effect.

### Configuring Suppression Timers

Suppression timers can prevent routing loops and reduce the possibility of generating incorrect routing information due to the receiving of incorrect routes.

### Context

When hop count of a route increases, a device starts suppression timers and accepts the Update packet of this route and updates the routing table until the suppression timers expire.

Suppression timers delays the addition of incorrect routes to the routing table and slows down route convergence on the entire network as well. Therefore, exercise caution when configuring the suppression timers.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run rip process-id

A RIP process is created, and the RIP view is displayed.

#### Step 3 Run timers rip update age suppress garbage-collect

The suppression timers are set.

#### Step 4 Run commit

The configuration is committed.

----End

### Follow-up Procedure

RIP has four timers: *update*, *age*, *suppress*, and *garbage-collect*. The value of *update* is less than that of *age*, and the value of *suppress* is less than that of *garbage-collect*. Setting improper values for the timers affects RIP convergence speed and even causes route flapping on the network. For example, if the value of *update* is greater than that of *age*, a device cannot inform its neighbors of the change of RIP routes immediately.

For the configurations of *update*, *age*, *suppress*, and *garbage-collect*, see [Configuring RIP Timers](#).

## Verifying the Configuration

After routing loop prevention is configured, you can view the current running status of RIP, information about interfaces, and RIP routing information.

### Prerequisites

Routing loop prevention has been configured.

### Procedure

- Run the **display rip [ process-id | vpn-instance vpn-instance-name ]** command to check RIP running status and configuration.
- Run the **display rip process-id route** command to check RIP routes.
- Run the **display rip process-id interface** command to check information about RIP interfaces.

----End

### 1.1.6.2.5 Adjusting RIP Route Selection

You can adjust RIP route selection on a complicated network.

### Usage Scenario

The implementation of RIP is simple, and therefore, RIP is widely used in small and medium networks. To flexibly apply RIP on the live network to meet various requirements of users, you can change RIP route selection by setting different parameters.

### Pre-configuration Tasks

Before adjusting RIP route selection, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.6.2.3 Configuring Basic RIP Functions](#).

### Configuration Procedure

Perform one or more of the following configurations as required.

### Disabling RIP-2 Classful Summarization

On the network where subnets are incontiguous, you can cancel the classful summarization of RIP-2 so that more accurate routing information can be obtained.

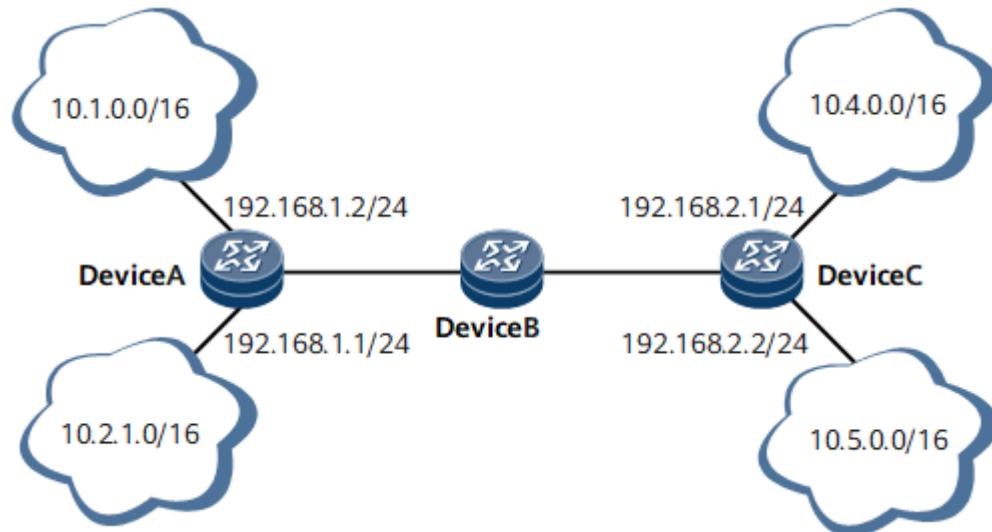

### Context

Summarizing IP addresses can reduce the routing table size, but it shields routing information of subnets. As a result, incorrect routing information may be calculated.

On a non-contiguous subnet, you need to disable RIP-2 classful summarization. On the network shown in [Figure 1-205](#), you need to disable split horizon from interfaces of Router A and Router C.

By default, RIP-2 classful summarization is enabled. Therefore, Router B and Router C send a route destined for 10.0.0.0/8 to Router A. Router A cannot differentiate 10.1.0.0/16, 10.2.0.0/16, 10.4.0.0/16, or 10.5.0.0/16. As a result, incorrect routes are calculated.

**Figure 1-205** Disabling RIP-2 classful summarization

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

**Step 3** Run **undo summary**

RIP-2 classful summarization is disabled.

**Step 4** Run **commit**

The configuration is committed.

----End

## Configuring the Additional Metric on an Interface

The additional metric is a metric (number of hops) that is added to the original metric of an RIP route. You set additional metrics for received RIP routes and those to be sent.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 3 Set the metric to be added to received routes.

Run any of the following commands as required:

- Based on the basic ACL:

a. Run **rip metricin { value | { acl-number| acl-name acl-name } value1 }**

The metric to be added to the received routes that match the specified basic ACL is configured.

b. Run **quit**

Return to the system view.

c. Run **acl { name basic-acl-name { basic | [ basic ] number basic-acl-number } | [ number ] basic-acl-number } [ match-order { config | auto } ]**

The ACL view is displayed.

d. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name ] \***

A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.
- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.
- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:

Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the

unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.

Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.

- Based on an IP prefix list:

Run **rip metricin { value | ip-prefix ip-prefix-name value1 }**

The metric to be added to the received routes that match the specified basic ACL is configured.

#### Step 4 Configure a metric to be added to the routes to be advertised by the interface.

Run any of the following commands as required:

- Based on the basic ACL:

- Run **rip metricout { value | { acl-number | acl-name acl-name } value1 }**  
\*

The metric to be added to the routes that match the specified basic ACL and are to be advertised is configured.

- Run **quit**

Return to the system view.

- Run **acl { name basic-acl-name { basic | [ basic ] number basic-acl-number } | [ number ] basic-acl-number } [ match-order { config | auto } ]**

The ACL view is displayed.

- Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name ] \***

A rule is configured for the ACL.

When the **rule** command is run to configure rules for a named ACL, only the source address range specified by **source** and the time period specified by **time-range** are valid as the rules.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.
- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.

- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:
  - Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.
  - Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.
- Based on an IP prefix list:

Run **rip metricout { value | ip-prefix ip-prefix-name value1 } \***

The metric to be added to the routes that match the specified IP prefix list and are to be advertised is configured.

#### NOTE

If an ACL or IP prefix list is specified in the **rip metricout** command to filter the received RIP routes to be advertised, the configured metric is added only to the matched routes. If a RIP route does not match the ACL or the IP prefix list, its metric is increased by 1. When an ACL or an IP prefix list is used with the **rip metricout** command, the additional metric ranges from 2 to 15.

#### Step 5 Run **commit**

The configuration is committed.

----End

### Setting the Maximum Number of Equal-Cost Routes

You can set the maximum number of equal-cost RIP routes to adjust the number of routes that load-balance traffic.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

#### Step 3 Run **maximum load-balancing number**

The maximum number of equal-cost routes is set.

#### Step 4 Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After adjusting RIP route selection, you can view the current running status of RIP, information about interfaces, and RIP routing information.

## Prerequisites

The configurations of adjusting RIP route selection have been performed.

## Procedure

- Run the **display rip [ process-id | vpn-instance vpn-instance-name ]** command to check RIP running status and configuration.
- Run the **display rip process-id route** command to check RIP routes.
- Run the **display rip process-id interface** command to check information about RIP interfaces.

----End

### 1.1.6.2.6 Controlling RIP Routing Information

In most cases, multiple protocols run on the same network. Therefore, you need to control routing information of every protocol to meet different networking requirements.

## Usage Scenario

To meet the requirements of complex networking, accurately control the sending and receiving of RIP routing information.

## Pre-configuration Tasks

Before configuring a router to control RIP routing information, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer
- [1.1.6.2.3 Configuring Basic RIP Functions](#)

## Configuration Procedure

Perform one or more of the following configurations as required.

### Configuring RIP to Import External Routes

A RIP process can import the routes learned by other processes or routing protocols to enrich routing entries.

## Context

On a large-scale network, different routing protocols may be configured for devices in different areas. To implement communication between a RIP area and other routing areas, you need to configure the device to import routes from other routing protocols.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run rip [ *process-id* ]

A RIP process is created, and the RIP view is displayed.

### Step 3 (Optional) Run default-cost *cost*

The default metric is configured for imported routes.

If no metric is specified for imported external routes, the default metric 0 is used.

### Step 4 Run import-route

The device is configured to import external routes.

- To import direct routes, static routes, IS-IS routes, OSPF routes, or routes of another RIP process, run the **import-route { static | direct | bgp | unr | { isis | ospf | rip } [ *process-id* ] } [ cost *cost* | { route-policy *route-policy-name* | route-filter *route-filter-name* } ]** \* command.
- To import IBGP routes, run the **import-route bgp permit-ibgp [ cost *cost* | { route-policy *route-policy-name* | route-filter *route-filter-name* } ]** \* or **import-route bgp [ permit-ibgp ] { cost transparent { route-policy *route-policy-name* | route-filter *route-filter-name* } | { route-policy *route-policy-name* | route-filter *route-filter-name* } cost transparent | cost transparent }** command.

#### NOTE

Importing routes from other protocols into a RIP process may lead to routing loops. Therefore, exercise caution when running the **import-route** command.

### Step 5 Run commit

The configuration is committed.

----End

## Configuring RIP to Advertise Default Routes

Default routes are destined for 0.0.0.0.

## Context

In a routing table, the default route is a route to 0.0.0.0 with mask 0.0.0.0. You can run the **display ip routing-table** command to check whether the default route is configured. When the destination address of a packet does not match any entry in the routing table, the router forward this packet along a default route.

If the default route and the destination address of the packet do not exist in the routing table, the router discards the packet and sends an Internet Control Message Protocol (ICMP) packet, informing the originating host that the destination address or network is unreachable.

After the **default-route originate** command is run, default routes are advertised to RIP neighbors only when there are default routes in the routing table, and the default route that is learned from a neighbor is deleted.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run rip [ process-id ]

A RIP process is created, and the RIP view is displayed.

### Step 3 Run default-route originate [ cost cost | tag tag | { match default | { route-policy route-policy-name [ advertise-tag ] | route-filter route-filter-name } } [ avoid-learning ] ] \*

RIP is enabled to advertise default routes.

### Step 4 Run commit

The configuration is committed.

----End

## Configuring RIP to Filter Received Routes

You can configure an import policy for a device so that the device receives only required routes.

## Context

You can configure an import policy by specifying an ACL or IP prefix list to filter received routes. You can also configure a device to receive only the RIP packets from a specified neighbor.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run rip [ process-id ]

A RIP process is created, and the RIP view is displayed.

### Step 3 Configure RIP to filter received routes.

- Run **filter-policy acl-number import** [ *interface-type interface-number* ]

The learned routes are filtered based on the ACL.

- Run **filter-policy gateway ip-prefix-name import**

The routes advertised by neighbors are filtered based on the IP prefix list.

- Run **filter-policy acl-name acl-name import** [ *interface-type interface-number* ]

The learned routes are filtered based on the named ACL.

- Run **filter-policy ip-prefix ip-prefix-name [ gateway ip-prefix-name ] import [ interface-type interface-number ]**  
The routes learned from the specified interface are filtered based on the IP prefix list or interface.

#### Step 4 Run commit

The configuration is committed.

----End

### Configuring RIP to Filter the Routes to Be Advertised

You can set conditions to filter the routes to be advertised. Only the routes that meet the conditions can be advertised.

### Context

Devices can filter the routing information. To filter the routes to be advertised, you can configure an export filtering policy by specifying the ACL and IP prefix list.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run rip [ process-id ]

A RIP process is created, and the RIP view is displayed.

#### Step 3 Set the conditions to filter the advertised routes.

Run any of the following commands as required:

- Based on the basic ACL:
  - Run **filter-policy { acl-number | acl-name acl-name } export [ bgp | direct | static | unr | { isis | ospf | rip } [ process-id ] | interface-type interface-number ]**
  - Run **quit**  
Return to the system view.
  - Run **acl { name basic-acl-name { basic | [ basic ] number basic-acl-number } | [ number ] basic-acl-number } [ match-order { config | auto } ]**  
The ACL view is displayed.
  - Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name ] \***  
A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.
- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.
- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:

Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.

Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.

- Based on the IP prefix:

```
Run filter-policy ip-prefix ip-prefix-name export [bgp | direct | static | unr | { isis | ospf | rip } [process-id] | interface-type interface-number]
```

#### Step 4 Run commit

The configuration is committed.

----End

### Disabling RIP from Receiving Host Routes

You can disable RIP from receiving host routes on a device to prevent the device from receiving a large number of unwanted routes. Such configuration can reduce network resource consumption.

### Context

In some situations, the router may receive a large number of host routes from the same network segment. These routes, useless for routing, consume many network resources. By disabling RIP from receiving host routes, you can configure the router to reject the received host routes.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

### Step 3 Run **undo host-route**

RIP is disabled from receiving host routes.

### Step 4 Run **commit**

The configuration is committed.

----End

## Disabling the Check on RIP Packets with Cost 0

To communicate with other devices supporting packets with cost 0, prevent the Huawei device from checking the RIP packets with cost 0.

## Context

On the live network, not all devices can receive the packets with cost 0. By default, devices do not accept the packets with cost 0. Therefore, RIP interfaces discard the RIP packets with cost 0. To implement communication between Huawei devices and the devices that can accept the packets with cost 0, run the **undo zero-metric-check** command to allow interfaces to accept the RIP packets with cost 0.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

### Step 3 Run **undo zero-metric-check**

The interface is allowed to receive RIP packets with cost 0.

### Step 4 Run **commit**

The configuration is committed.

----End

## Follow-up Procedure

To enable the check on the RIP packets with cost 0, run the **zero-metric-check** command.

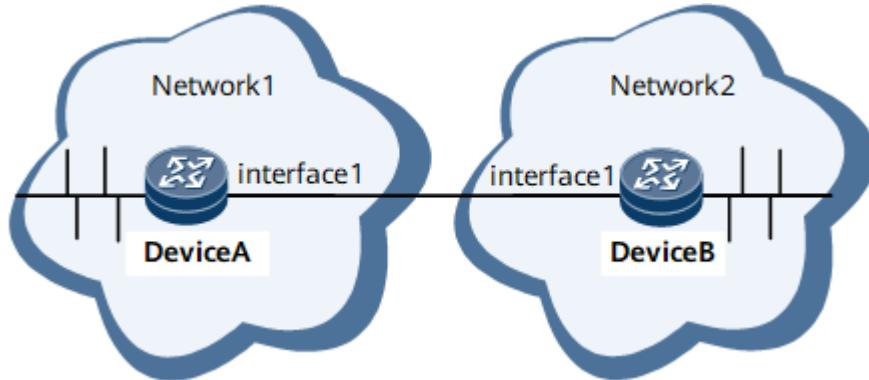

## Disabling an Interface from Sending Packets

When you do not need an interface connected to an external network to send routing information, disable the interface from sending RIP packets.

### Usage Scenario

On the network shown in [Figure 1-206](#), RIP-enabled Network 1 is connected to Network 2 through the edge device Device A. You can disable the interface on Device A from sending packets.

**Figure 1-206** Scenario where an interface is disabled from sending packets

### Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **interface interface-type interface-number**

The interface view is displayed.

**Step 3** Run **undo rip output**

The interface is disabled from sending RIP packets.

**Step 4** Run **commit**

The configuration is committed.

----End

## Disabling an Interface from Receiving Packets

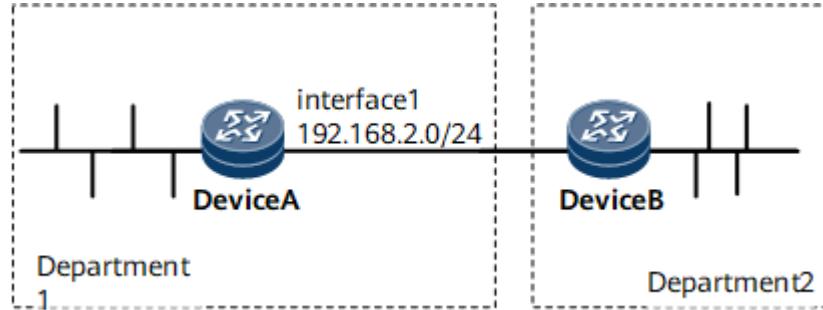

If an interface does not need to learn routing information from neighbors, you can disable the interface from receiving RIP packets.

### Usage Scenario

On an enterprise network where departments are not allowed to communicate with each other, you can disable interfaces from receiving packets.

On the network shown in [Figure 1-207](#), if you do not want Department 1 to learn routing information about Department 2, you can disable the interface on Device A from receiving packets.

**Figure 1-207** Scenario where an interface is disabled from receiving packets

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **interface interface-type interface-number**

The interface view is displayed.

**Step 3** Run **undo rip input**

The interface is disabled from receiving RIP packets.

**Step 4** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After RIP routing information is successfully controlled, you can view all active routes in the RIP database and the current running status.

## Prerequisites

The configurations for controlling RIP routing information have been performed.

## Procedure

- Run the **display rip process-id database** command to check all active routes in the RIP database.
- Run the **display rip process-id** command to check the running status and configurations of the specified RIP process.

----End

### 1.1.6.2.7 Configuring RIP Fast Convergence

The network convergence speed is one of the key factors used to evaluate network performance.

#### Usage Scenario

The route convergence speed on a device is a performance index used to measure the network quality. Fast route convergence can improve the accuracy of routing information on the network.

#### Pre-configuration Tasks

Before configuring RIP fast convergence, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.6.2.3 Configuring Basic RIP Functions](#)

#### Configuration Procedure

Perform one or more of the following configurations as required.

##### Configuring RIP-2 Route Summarization

Configuring RIP-2 route summarization reduces the routing table size, which improves system performance and network security.

#### Context

On a medium-or large-sized network, the routing table contains a large number of routes. Storing and managing the routes consume a large number of memory resources. To resolve this problem, RIP-2 provides the route summarization function. Route summarization allows multiple routes with the same IP prefix and destination IP address to be summarized into one, which reduces the number of routes in the routing table and minimizes system resource consumption. In addition, if a specific link frequently alternates between Up and Down, the links not involved in the route summarization will not be affected, which prevents route flapping and improves network stability.

##### NOTE

RIP-1 does not support route summarization.

#### Procedure

- Enable RIP-2 automatic route summarization.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **rip [ process-id ]**  
A RIP process is created, and the RIP view is displayed.
  - c. Run **summary [ always ]**

RIP-2 automatic route summarization is enabled.

 NOTE

If you specify **always**, RIP-2 automatic route summarization takes effect, regardless of whether split horizon and poison reverse has been configured.

d. Run **commit**

The configuration is committed.

- Configure RIP-2 to advertise the summarized route.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **rip summary-address ip-address mask [ avoid-feedback ]**

RIP-2 is configured to advertise the summarized route to the specified IP address.

If you specify **avoid-feedback**, the local interface does not learn the summarized route whose destination address is the same as that of the advertised summarized route, which prevents routing loops.

d. Run **commit**

The configuration is committed.

----End

## Configuring RIP Timers

There are four RIP timers: Update, Age, Suppress, and Garbage-collect timers. You can adjust the RIP convergence speed by changing the values of RIP timers.

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

**Step 3** Run **timers rip update age suppress garbage-collect**

RIP timers are configured.

**Step 4** Run **commit**

The configuration is committed.

----End

## Follow-up Procedure

The value of *update* is less than that of *age*, and the value of *suppress* is less than that of *garbage-collect*. Setting improper values for the timers affects RIP

convergence speed and even causes route flapping on the network. For example, if the value of *update* is greater than that of *age*, a device cannot inform its neighbors of the change of RIP routes immediately.

Configuring the Suppress timer can prevent routing loops. For details, see [Configuring Suppression Timers](#).

## Configuring RIP Triggered Update

You can speed up network convergence by changing the values of triggered update timers.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

#### Step 3 Run **timers rip triggered { minimum-interval *minimum-interval* | incremental-interval *incremental-interval* | maximum-interval *maximum-interval* } \***

RIP triggered update timers are configured.

#### Step 4 Run **commit**

The configuration is committed.

----End

## Setting the Interval at Which Packets Are Sent and the Maximum Number of the Sent Packets

You can set the interval at which RIP packets are sent and the maximum number of packets that can be sent at a time to control the memory used by a device to process RIP update packets.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface *interface-type interface-number***

The interface view is displayed.

#### Step 3 Run **rip pkt-transmit { interval *interval* | number *pkt-count* | bandwidth *bandwidth-value* } \***

The interval at which RIP packets are sent and the maximum number of packets sent each time are set by the interface.

#### Step 4 Run **commit**

The configuration is committed.

----End

## Setting the Maximum Length of RIP packets

You can increase the maximum length of RIP packets to enable them to carry more routes, which improves bandwidth utilization.

### Context

#### NOTICE

You can run the **rip max-packet-length** command to set a length greater than 512 bits for RIP packets only when the remote end can accept RIP packets longer than 512 bits.

After the maximum length of RIP packets is increased, Huawei devices may fail to communicate with non-Huawei devices. Therefore, exercise caution when running this command.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

#### Step 3 Run **rip max-packet-length { value | mtu }**

The maximum length of RIP packets is set.

**mtu** specifies the maximum length of a RIP packet that can be accepted.

#### Step 4 Run **commit**

The configuration is committed.

----End

## Setting the Maximum Number of RIP Routes

You can set the maximum number of RIP routes to make full use of network resources and improve network performance.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

**Step 3** Run **maximum-routes max-number [ threshold threshold-value ]**

The maximum number of routes is set.

**Step 4** Run **commit**

The configuration is committed.

----End

## Configuring RIP Hardware Replication

After RIP hardware replication is configured, RIP packets can be forwarded in hardware replication mode. This implements fast forwarding and optimizes system performance.

### Context

If a device has dot1q VLAN tag termination sub-interfaces, QinQ VLAN tag termination sub-interfaces, and user VLAN sub-interfaces and these sub-interfaces are configured with a large number of VLANs, protocol packets to be forwarded need to be replicated and broadcast in these VLANs. This increases the CPU load and may even cause problems such as packet replication and sending failures. To solve the problems, enable hardware replication for RIPv2 packets. After this function is enabled, hardware replicates the protocol packets to be broadcast, which reduces CPU consumption.

### Procedure

- Enable hardware replication on a dot1q VLAN tag termination sub-interface.
  - a. Run the **system-view** command to enter the system view.
  - b. Run the **interface interface-type interface-number . subinterface-number** command to enter the sub-interface view.
  - c. Run the **encapsulation dot1q-termination** command to configure the sub-interface as a dot1q VLAN tag termination sub-interface.
  - d. Run the **rip-broadcast-copy fast enable** command to enable hardware replication for RIPv2 packets.
  - e. Run the **commit** command to commit the configuration.
- Enable hardware replication on a QinQ VLAN tag termination sub-interface.
  - a. Run the **system-view** command to enter the system view.
  - b. Run the **interface interface-type interface-number . subinterface-number** command to enter the sub-interface view.
  - c. Run the **encapsulation qinq-termination** command to configure the sub-interface as a QinQ VLAN tag termination sub-interface.
  - d. Run the **rip-broadcast-copy fast enable** command to enable hardware replication for RIPv2 packets.
  - e. Run the **commit** command to commit the configuration.
- Enable hardware replication on a user VLAN sub-interface.
  - a. Run the **system-view** command to enter the system view.
  - b. Run the **interface interface-type interface-number . subinterface-number** command to enter the sub-interface view.

- c. Run the **user-vlan { start-vlan-id [ end-vlan-id ] | cevlan } qinq { start-pe-vlan [ end-pe-vlan ] | pevlan }** command to configure the sub-interface as a user VLAN sub-interface.
- d. Run the **rip-broadcast-copy fast enable** command to enable hardware replication for RIPv2 packets.
- e. Run the **commit** command to commit the configuration.

----End

## Verifying the Configuration

After configuring fast RIP convergence, check the running status of RIP, RIP routing information, all active routes in the RIP database, and information about interfaces.

## Prerequisites

Fast RIP convergence has been configured.

## Procedure

- Run the **display rip [ process-id | vpn-instance vpn-instance-name ]** command to check RIP running status and configuration.
- Run the **display rip process-id route** command to check RIP routes.
- Run the **display rip process-id database [ verbose ]** command to check all active routes in the RIP database.
- Run the **display rip process-id interface [ interface-type interface-number ] [ verbose ]** command to check information about RIP interfaces.

----End

### 1.1.6.2.8 Configuring Dynamic BFD for RIP

On a network that runs high-rate data services, dynamic BFD for RIP can be configured to quickly detect and respond to network faults.

## Usage Scenario

RIP-capable devices detect neighbor status by exchanging Update packets periodically. The default value of the aging timer is 180s. If a link fault occurs, RIP can detect the fault only after 180s. During this period, carriers or users may lose a large number of packets.

BFD can detect a fault (if any) within milliseconds and notify the RIP module of the fault. BFD for RIP can speed up fault detection and route convergence, which improves network reliability.

In BFD for RIP, BFD session establishment is triggered by RIP. When establishing a neighbor relationship, RIP will send detection parameters of the neighbor to BFD. Then, a BFD session will be established based on these detection parameters. If a link fault occurs, the local RIP process will receive a neighbor unreachable message within milliseconds. Then, the local RIP device will delete routing entries in which the neighbor relationship is Down and use the backup path to transmit messages.

Either of the following methods can be used to configure BFD for RIP:

- **Enable BFD in a RIP process:** This method is feasible when BFD for RIP needs to be enabled on most RIP interfaces.
- **Enable BFD on RIP interface:** This method is recommended when BFD for RIP needs to be enabled only on a small number of RIP interfaces.

 **NOTE**

The interface can be a physical interface or a GRE tunnel interface. If BFD is enabled on a GRE tunnel interface, millisecond-level fault detection can be implemented for the GRE tunnel.

## Pre-configuration Tasks

Before configuring BFD for RIP, complete the following tasks:

- Assign an IP address to each interface to ensure that neighboring nodes are reachable at the network layer.
- **Configuring Basic RIP Functions**

## Procedure

- Enable BFD in a RIP process.

a. Run **system-view**

The system view is displayed.

b. Run **bfd**

BFD is enabled globally.

c. Run **quit**

Return to the system view.

d. Run **rip process-id**

The RIP view is displayed.

e. Run **bfd all-interfaces enable**

BFD is enabled in the RIP process to establish BFD sessions.

If BFD is enabled globally, RIP will use default BFD parameters to establish BFD sessions on all the interfaces where RIP neighbor relationships are up in the process.

f. (Optional) Run **bfd all-interfaces { min-rx-interval min-receive-value | min-tx-interval min-transmit-value | detect-multiplier detect-multiplier-value } \***

The values of BFD parameters used to establish the BFD session are set.

Configure BFD parameter values based on the reliability requirements of the live network.

- If the live network requires high reliability, reduce the interval at which BFD packets are sent.
- If the live network requires low reliability, increase the interval at which BFD packets are sent.

BFD detection intervals are calculated as follows:

- Effective local interval at which BFD packets are sent = MAX { Configured local interval at which BFD packets are sent, Configured remote interval at which BFD packets are received }
- Effective local interval at which BFD packets are received = MAX { Configured remote interval at which BFD packets are sent, Configured local interval at which BFD packets are received }
- Effective local detection interval = Effective local interval at which BFD packets are received x Configured remote detection multiplier

Running the **bfd all-interfaces** command changes BFD session parameters on all RIP interfaces. The default detection multiplier and interval at which BFD packets are sent are recommended.

- g. (Optional) Perform the following operations to prevent an interface in the RIP process from establishing a BFD session:

- Run the **quit** command to return to the system view.
- Run the **interface interface-type interface-number** command to enter the view of a specified interface.
- Run the **rip bfd block** command to prevent the interface from establishing a BFD session.

- h. Run **commit**

The configuration is committed.

- Enable BFD on a RIP interface.

- a. Run **system-view**

The system view is displayed.

- b. Run **bfd**

BFD is enabled globally.

- c. Run **quit**

Return to the system view.

- d. Run **interface interface-type interface-number**

The view of the specified interface is displayed.

- e. Run **rip bfd enable**

BFD is enabled on the interface to establish a BFD session.

- f. (Optional) Run **rip bfd { min-rx-interval min-receive-value | min-tx-interval min-transmit-value | detect-multiplier detect-multiplier-value }**  
\*

The values of BFD parameters used to establish the BFD session are set.

- g. Run **commit**

The configuration is committed.

----End

## Checking the Configurations

After enabling BFD for RIP at both ends of a link, run the **display rip bfd session { interface interface-type interface-number | neighbor-id | all }** command. The following command output shows that the **BFDState** field on the local router is Up.

### 1.1.6.2.9 Configuring Static BFD for RIP

BFD provides link failure detection featuring light load and high speed. Static BFD for RIP is a mode to implement the BFD function.

## Context

Establishing BFD sessions between RIP neighbors enables the rapid detection of link faults and speeds up RIP's response to network topology changes. On a link that requires fast fault response and supports BFD on both ends, you can configure static BFD on both ends to implement common BFD detection.

To configure a static BFD session, you need to manually configure BFD detection using commands and deliver a BFD session establishment request.

## Pre-configuration Tasks

Before configuring static BFD for RIP, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring devices are reachable at the network layer.
- Configure basic RIP functions.**

## Data Preparation

To complete the configuration, you need the following data:

| No. | Data                                                    |
|-----|---------------------------------------------------------|
| 1   | ID of a RIP process                                     |
| 2   | Type and number of the interface to be enabled with BFD |

## Procedure

### Step 1 Enable BFD globally.

- Run the **system-view** command to enter the system view.
- Run the **bfd** command to enable BFD globally.
- Run the **quit** command to return to the system view.

### Step 2 Configure static BFD.

- Run the **bfd session-name bind peer-ip peer-ip [ interface interface-type interface-number ] [ source-ip source-ip ]** command to create BFD binding.

If both **peer-ip** (IP address of the peer end) and **interface** (local interface) are specified, BFD only monitors a single-hop link with **interface** as the outbound interface and **peer-ip** as the next hop address.

2. Set discriminators.

- To set the local discriminator, run the **discriminator local *discr-value*** command.
- To set the remote discriminator, run the **discriminator remote *discr-value*** command.

The local device's local discriminator and remote discriminator must be the same as the remote device's remote discriminator and local discriminator, respectively. Otherwise, a BFD session cannot be established.

 NOTE

Specifically, **local *discr-value*** of the local device must be the same as the **remote *discr-value*** of the remote device, and **remote *discr-value*** of the local device must be the same as **local *discr-value*** of the remote device.

3. Run the **quit** command to return to the system view.

**Step 3** Enable static BFD on an interface.

1. Run the **interface *interface-type interface-number*** command to enter the view of a specified interface.
2. Run the **rip bfd static** command to enable static BFD on the interface.
3. (Optional) Run the **rip bfd static binding *peer-address*** command to enable static BFD for the specified neighbor.

 NOTE

If you run both this command and the **rip bfd static** command, the latest configuration overrides the previous one. If the command is run, the existing BFD configuration mode will be changed.

**Step 4** Run the **commit** command to commit the configuration.

----End

## Verifying the Configuration

After configuring static BFD for RIP, run the **display rip process-id interface [*interface-type interface-number*] verbose** command to check the BFD for RIP configuration on a specified interface.

### 1.1.6.2.10 Configuring OPS to Control Packet Sending and Receiving on RIP Interfaces

This section describes how to prevent the failure of switching traffic to the backup path in a scenario where static unaffiliated BFD for RIP is configured and a link is available unidirectionally.

## Context

**Figure 1-208** shows an unaffiliated static BFD for RIP scenario where primary and backup paths exist. If the link from DeviceA to DeviceB on the primary path fails,

BFD on DeviceA rapidly detects the link fault, and the RIP route on DeviceA rapidly converges to the backup path. Because DeviceB does not support BFD or is not configured with BFD, DeviceB cannot rapidly detect the link fault. As a result, the RIP route on DeviceB cannot converge rapidly. In this case, DeviceB continues to send RIP packets to DeviceA. After DeviceA re-learns the RIP route from DeviceB, traffic is switched from the backup path to the primary path. However, the link from DeviceA to DeviceB is still faulty. As a result, traffic cannot be forwarded.

**Figure 1-208** Networking diagram of unaffiliated static BFD for RIP

Static BFD for RIP is enabled on DeviceA.

## Pre-configuration Tasks

Before configuring OPS to control packet sending and receiving on RIP interfaces, complete the following task:

- [Configure static BFD for RIP](#).

## Precautions

- The OPS mechanism allows a single script assistant to cache a maximum of 256 alarms. Therefore, this function does not apply to the scenario where BFD goes down due to a large number of link faults.
- After this function is enabled, you are advised not to perform an active/standby switchover, restart the device, or modify static BFD for RIP configurations when a link is faulty. Otherwise, the command for disabling an interface from receiving and sending RIP packets may fail to be deleted, causing a residual configuration.
- Broadcast network scenarios are not supported.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ops**

The OPS view is displayed.

### Step 3 Run **script-assistant python ripbfd\_down\_mtp.py**

A script assistant is created.

 NOTE

After this function is enabled, if BFD Down alarm information is received, the script assistant obtains information about the interface corresponding to the faulty link from the alarm information and determines whether to disable the interface from sending and receiving RIP packets based on whether the **rip bfd static** command is configured on the interface.

- If the **rip bfd static**, **undo rip output**, and **undo rip input** commands are run on the interface, the interface is disabled from sending and receiving RIP packets.
- If the **rip bfd static** command is not run on the interface, the interface is not affected.

**Step 4** Run **script-assistant python ripbfd\_up\_mtp.py**

A script assistant is created.

 NOTE

After this function is enabled, if BFD Down alarm clearing information is received, the script assistant obtains information about the interface corresponding to the faulty link from the alarm information and determines whether to allow the interface to send and receive RIP packets based on whether the **rip bfd static** command is configured on the interface.

- If the **rip bfd static**, **rip output**, and **rip input** commands are run on the interface, the interface is allowed to send and receive RIP packets.
- If the **rip bfd static** command is not run on the interface, the interface is not affected.

**Step 5** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

Run the **display ops assistant current** command to check the current status of script assistants.

### 1.1.6.2.11 Improving the RIP Network Security

On a network requiring high security, you can configure RIP authentication and Generalized TTL Security Mechanism (GTSM) to improve network security.

## Usage Scenario

With the increase in attacks on TCP/IP networks and the defects in the TCP/IP protocol suite, network attacks have increasing impacts on the network security. Attacks on network devices may even cause a network crash or lead to network unavailability. Therefore, it is necessary to protect the network from attacks. RIP uses the following methods to ensure network security:

- RIP authentication: RIP checks the authentication mode and password in each packet to protect the local device against potential attacks.
- Check on the source IP address of each packet: RIP interfaces accept packets only from the same network to protect the local device from potential attacks from other networks.
- RIP GTSM: GTSM protects the local router by checking whether the time to live (TTL) value in the IP packet header is in a pre-defined range.

## Pre-configuration Tasks

Before improving RIP network security, complete the following tasks:

- Configure network layer addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.6.2.3 Configuring Basic RIP Functions](#)

## Configuration Procedure

Perform one or more of the following configuration tasks (excluding verifying the configuration) as required.

### Configuring an Authentication Mode for RIP-2 Packets

RIP-2 supports authentication for protocol packets. By default, authentication is not configured for RIP. Configuring authentication is recommended to ensure system security.

## Procedure

### Step 1 Run `system-view`

The system view is displayed.

### Step 2 Run `interface interface-type interface-number`

The interface view is displayed.

### Step 3 Perform the following operations as required:

- Run `rip authentication-mode simple { plain plain-text | [ cipher ] password-key }`  
Simple authentication is configured for RIP-2 packets.  
In simple authentication mode, the password in simple text mode is transmitted along with each authentication packet. Therefore, simple authentication is not recommended on networks requiring high security.
- Run `rip authentication-mode md5 { nonstandard { { plain plain-text | [ cipher ] password-key } key-id | keychain keychain-name } | usual { plain plain-text | [ cipher ] password-key } }`  
Message Digest 5 (MD5) authentication is configured for RIP-2 packets.  
In MD5 authentication mode, the MD5 password is used for packet encapsulation and decapsulation. MD5 authentication is more secure than simple authentication.

**nonstandard** supports nonstandard authentication packets.

**usual** supports Internet Engineering Task Force (IETF) standard authentication packets.

#### NOTE

For the sake of security, using the HMAC-SHA256 algorithm rather than the MD5 algorithm is recommended.

- Run `rip authentication-mode hmac-sha256 { plain plain-text | [ cipher ] password-key } key-id`

Hash Message Authentication Code for Secure Hash Algorithm 256 (HMAC-SHA256) authentication is configured.

### NOTICE

When configuring an authentication password, select the ciphertext mode because the password is saved in the configuration file as a plaintext if you select the plaintext mode, which has a high risk. To ensure device security, change the password periodically.

For security purposes, you are not advised to use the weak security algorithm in RIP. If you need to use the weak security algorithm, run the **undo crypto weak-algorithm disable** command to enable the weak security algorithm function first.

#### Step 4 Run commit

The configuration is committed.

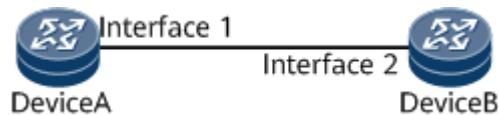

----End

### Result

The following section describes the changes in the RIP neighbor relationship and data traffic during the upgrade from RIP-1 to RIP-2 with authentication.

**Scenario 1:** [Figure 1-209](#) shows a P2P topology, and an upgrade is performed. DeviceA and DeviceB use the default configuration.

**Figure 1-209** RIP neighbor relationship over a P2P link

With the default configuration, packet sending and receiving on one end of the P2P link are the same as those on the other end.

Interface 1 on DeviceA: (Default version or RIP-1-compatible version)

Send: RIP-1

Receive: RIP-1; RIP-2 in broadcast or multicast mode

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)

Send: RIP-1

Receive: RIP-1; RIP-2 in broadcast or multicast mode

- Step 1: Configure authentication on interface 1 of DeviceA.

Interface 1 on DeviceA: (Default version or RIP-1-compatible version)

Send: RIP-1

Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information

DeviceB: (Default version or RIP-1-compatible version)

Send: RIP-1

Receive: RIP-1; RIP-2 in broadcast or multicast mode

Authentication applies to RIP-2 packets, not to RIP-1 packets; however, the packets exchanged between DeviceA and DeviceB are RIP-1 packets.

Therefore, the RIP neighbor relationship and data traffic remain unchanged after this step is performed.

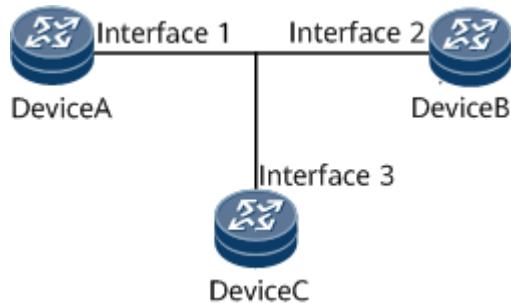

- Step 2: Configure the same authentication mode on interface 2 of DeviceB.  
Interface 1 on DeviceA: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information  
  
Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information  
  
Authentication applies to RIP-2 packets, not to RIP-1 packets; however, the packets exchanged between DeviceA and DeviceB are RIP-1 packets. Therefore, the RIP neighbor relationship and data traffic remain unchanged after this step is performed.
- Step 3: Configure RIP-2 in broadcast mode on interface 1 of DeviceA.  
Interface 1 on DeviceA: (RIP-2 in broadcast mode)  
Send: RIP-2 in broadcast mode, with authentication information  
Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information  
  
Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information  
  
DeviceA broadcasts RIP-2 packets with authentication information to DeviceB. Because the same authentication mode is configured on DeviceB, DeviceB accepts these packets. DeviceB sends RIP-1 packets without authentication information to DeviceA, which accepts the RIP-1 packets although it runs RIP-2 (in broadcast mode with authentication information).  
In this case, the neighbor relationship and data traffic are not affected.
- Step 4: Configure RIP-2 in broadcast mode on interface 2 of DeviceB.  
Interface 1 on DeviceA: (RIP-2 in broadcast mode)  
Send: RIP-2 in broadcast mode, with authentication information  
Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information  
  
Interface 2 on DeviceB: (RIP-2 in broadcast mode)  
Send: RIP-2 in broadcast mode, with authentication information  
Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information  
  
DeviceA and DeviceB exchange RIP-2 packets carrying authentication information in broadcast mode. Because authentication is configured on both DeviceA and DeviceB, both DeviceA and DeviceB can accept broadcast RIP-2 packets. In this case, the neighbor relationship and data traffic are not affected.
- Step 5: Configure RIP-2 on interface 1 of DeviceA.  
Interface 1 on DeviceA: (RIP-2 in broadcast mode)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in broadcast and multicast mode, with authentication information  
  
Interface 2 on DeviceB:  
Send: RIP-2 in broadcast mode, with authentication information  
Receive: RIP-1; RIP-2 in broadcast or multicast mode, with authentication information  
  
DeviceA and DeviceB exchange RIP-2 packets carrying authentication information in multicast mode. Because authentication has been configured on DeviceB, Device B accepts the packets from DeviceA. DeviceB broadcasts RIP-2 packets with authentication information to DeviceA, which accepts the packets although it runs RIP-2. In this case, the neighbor relationship and data traffic are not affected.
- Step 6: Configure RIP-2 on interface 2 of DeviceB.  
Interface 1 on DeviceA: (RIP-2)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in multicast or broadcast mode, with authentication information

Interface 2 on DeviceB: (RIP-2)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in multicast or broadcast mode, with authentication information

DeviceA and DeviceB multicast RIP-2 packets with authentication information to each other. Because authentication is configured on DeviceA and DeviceB, they can exchange the multicast RIP-2 packets. In this case, the neighbor relationship and data traffic are not affected.

**Scenario 2:** [Figure 1-210](#) shows a broadcast topology, and an upgrade from RIP-1 (or RIP-1-compatible version) to RIP-2 is performed on devices.

**Figure 1-210** RIP neighbor relationship over a broadcast link

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode

Interface 1 on DeviceA: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

Interface 3 on DeviceC: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

#### NOTE

All devices in the networking use interface-level RIP configuration.

- Step 1: Configure authentication on DeviceA.

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode

Interface 1 on DeviceA: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

Interface 3 on DeviceC: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

Authentication applies to RIP-2 packets, not to RIP-1 packets. Therefore, the authentication on a RIP-1 interface does not affect RIP-1 packets.

- Step 2: Configure authentication on DeviceC.

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode

Interface 1 on DeviceA: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

Interface 3 on DeviceC: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

Authentication applies to RIP-2 packets, not to RIP-1 packets. Therefore, the authentication on a RIP-1 interface does not affect RIP-1 packets.

- Step 3: Configure authentication on DeviceB.

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

Interface 3 on DeviceC: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

Authentication applies to RIP-2 packets, not to RIP-1 packets. Therefore, the authentication on an interface that runs RIP of the default version (RIP-1) does not affect RIP-1 packets. If RIP-2 packets are received, they are accepted only after they are authenticated. No RIP-2 packets are sent in this scenario. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 4: Run the **undo version** command on DeviceA.

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (RIP-1)  
Send: RIP-1  
Receive: RIP-1

If the **undo rip version 1** command is run on the interface of DeviceB, the interface uses RIP of the default version (RIP-1) or RIP-1-compatible version. All the devices exchange RIP-1 packets in this scenario. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 5: Run the **undo version** command on DeviceC.

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (Default version or RIP-1-compatible version)  
Send: RIP-1  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

If the **undo rip version 1** command is run on the interface of DeviceC, the interface uses RIP-1 (default version) or RIP-1-compatible version. All the devices exchange RIP-1 packets in this scenario. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 6: Configure RIP-2 in broadcast mode on DeviceA.

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)  
Send: RIP-1

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (RIP-2 in broadcast mode)

Send: RIP-2 in broadcast mode, with authentication information

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (Default version or RIP-1-compatible version)

Send: RIP-1

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

If the **rip version 2 broadcast** command is run on the interface of DeviceA, the interface broadcasts RIP-2 packets with authentication information.

Because authentication is configured on other devices, they accept the RIP-2 packets from DeviceA and respond with RIP-1 packets. DeviceA accepts these RIP-1 packets. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 7: Configure RIP-2 in broadcast mode on DeviceC.

Interface 2 on DeviceB: (Default version or RIP-1-compatible version)

Send: RIP-1

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (RIP-2 in broadcast mode)

Send: RIP-2 in broadcast mode, with authentication information

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (RIP-2 in broadcast mode)

Send: RIP-2 in broadcast mode, with authentication information

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

If the **rip version 2 broadcast** command is run on the interface of DeviceC, the interface broadcasts RIP-2 packets with authentication information.

Because authentication is configured on other devices, they accept the RIP-2 packets from DeviceC. Device B still broadcasts RIP-1 packets. Upon receipt of these packets, DeviceA and DeviceC accept them. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 8: Configure RIP-2 in broadcast mode on DeviceB.

Interface 2 on DeviceB: (RIP-2 in broadcast mode)

Send: RIP-2 in broadcast mode, with authentication information

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (RIP-2 in broadcast mode)

Send: RIP-2 in broadcast mode, with authentication information

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (RIP-2 in broadcast mode)

Send: RIP-2 in broadcast mode, with authentication information

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

If the **rip version 2 broadcast** command is run on the interface of DeviceB, the interface broadcasts RIP-2 packets with authentication information.

Because authentication is configured on other devices, they accept the RIP-2 packets from DeviceB and also broadcast RIP-2 packets with authentication information. All the devices accept packets from each other. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 9: Configure RIP-2 on DeviceA.

Interface 2 on DeviceB: (RIP-2 in broadcast mode)

Send: RIP-2 in broadcast mode, with authentication information

Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (RIP-2)

Send: RIP-2 in multicast mode, with authentication information

Receive: RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (RIP-2 in broadcast mode)  
Send: RIP-2 in broadcast mode, with authentication information  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

If the **rip version 2** command is run on the interface of DeviceA, the interface multicasts RIP-2 packets with authentication information. Because authentication is configured on other devices, they accept the RIP-2 packets from DeviceA and broadcast RIP-2 packets with authentication information. All the interfaces accept packets from each other. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 10: Configure RIP-2 on DeviceC.

Interface 2 on DeviceB: (RIP-2 in broadcast mode)  
Send: RIP-2 in broadcast mode, with authentication information  
Receive: RIP-1; RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (RIP-2)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (RIP-2)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in multicast or broadcast mode, with authentication information

If the **rip version 2** command is run on the interface of DeviceC, the interface multicasts RIP-2 packets with authentication information. Because authentication is configured on other devices, they accept the RIP-2 packets from DeviceC. DeviceB broadcasts RIP-2 packets with authentication information, and DeviceA multicasts RIP-2 packets with authentication information. All the devices accept packets from each other. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

- Step 11: Configure RIP-2 on DeviceB.

Interface 2 on DeviceB: (RIP-2)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in multicast or broadcast mode, with authentication information

Interface 1 on DeviceA: (RIP-2)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in multicast or broadcast mode, with authentication information

Interface 3 on DeviceC: (RIP-2)  
Send: RIP-2 in multicast mode, with authentication information  
Receive: RIP-2 in multicast or broadcast mode, with authentication information

If the **rip version 2** command is run on the interface of DeviceB, the interface multicasts RIP-2 packets with authentication information. Because authentication is configured on other devices, they accept the RIP-2 packets from DeviceB and multicast RIP-2 packets with authentication information. All the devices accept packets from each other. Therefore, the RIP neighbor relationships and data traffic remain unchanged after this step is performed.

### Scenario 3: RIP-2 or RIP-2 in broadcast mode is enabled on all devices.

In this scenario, if RIP authentication is configured on all devices, packets may be discarded in the following cases because authentication configuration synchronization cannot be ensured during authentication:

1. RIP packets with authentication information are received by interfaces without authentication configuration.
2. RIP packets without authentication information are received by interfaces with authentication configuration.

After all the configurations are performed, RIP packets are authenticated and accepted by all interfaces with authentication configuration. When the default timer is used, RIP considers a route invalid only if it does not receive any Update packet within six update intervals. Therefore, if all the configurations are completed within the six update intervals, no traffic is interrupted.

## Configuring the Check on the Source Address in RIP Packets on the Broadcast Network

By default, RIP checks the source addresses of received packets, and the local RIP interface receives only the packets from the same network.

### Context

RIP interfaces check the source address in received RIP packets. If the source address of the received RIP packet is from a network segment different from that of the local interface IP address, the local interface discards this RIP packet. This improves the network security.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **rip [ process-id ]**

A RIP process is created, and the RIP view is displayed.

#### Step 3 Run **verify-source**

The source address check is configured for RIP packets on the broadcast network.

#### Step 4 Run **commit**

The configuration is committed.

----End

## Configuring GTSM for RIP

Generalized TTL Security Mechanism (GTSM) defends against attacks by checking the TTL value.

### Context

During network attacks, attackers may simulate RIP packets and continuously send them to a router. If the packets are destined for the router, it directly forwards them to the control plane for processing without validating them. As a result, the increased processing workload on the control plane results in high CPU usage. Generalized TTL Security Mechanism (GTSM) defends against attacks by checking whether the time to live (TTL) value in each IP packet header is within a pre-defined range.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **rip valid-ttl-hops valid-ttl-hops-value [ vpn-instance vpn-instance-name ]**

GTSM is configured for RIP.

The valid TTL range of the detected packets is [ 255 -*valid-ttl-hops-value* + 1, 255 ].

### Step 3 Run **commit**

The configuration is committed.

### Step 4 Set the default action for packets that do not match the GTSM policy.

GTSM only checks the TTL values of packets that match the GTSM policy. Packets that do not match the GTSM policy can be allowed or dropped.

You can enable the log function to record packet drop for troubleshooting.

Perform the following configurations on the GTSM-enabled router:

#### 1. Run **system-view**

The system view is displayed.

#### 2. Run **gtsm default-action { drop | pass }**

The default action for packets that do not match the GTSM policy is configured.

If the default action is configured but no GTSM policy is configured, GTSM does not take effect.

This command is supported only on the Admin-VS and cannot be configured in other VSs. This command takes effect on all VSs.

#### 3. Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After the security function of RIP is successfully configured, you can view information about RIP interfaces and the current running status of RIP.

## Prerequisites

The configurations for enhancing RIP network security have been performed.

## Procedure

- Run the **display rip process-id interface [ interface-type interface-number ] [ verbose ]** command to check information about RIP interfaces.

- Run the **display rip process-id** command to check the running status and configurations of the specified RIP process.

----End

### 1.1.6.2.12 Configuring RIP Network Management

By binding RIP and MIBs, you can view and configure RIP through the NMS.

#### Usage Scenario

Through Simple Network Management Protocol (SNMP), the RIP Management Information Base (MIB) manages multicast information exchanged between the NMS and agents.

#### Pre-configuration Tasks

Before controlling RIP configuration through an SNMP agent, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.6.2.3 Configuring Basic RIP Functions](#)

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **rip mib-binding process-id**

The MIB is bound to the RIP process ID, and the ID of the RIP process that accepts SNMP requests is specified.

##### Step 3 Run **commit**

The configuration is committed.

----End

#### Checking the Configurations

Run the following commands to check the previous configuration.

- Run the **display current-configuration** command to check the valid parameters on the device.

### 1.1.6.2.13 Maintaining RIP

RIP maintenance is implemented through debugging which affects system performance.

#### Clearing RIP

If you want to clear information about RIP, run the reset commands in the user view.

## Context

### NOTICE

RIP information cannot be restored after you clear it. Therefore, exercise caution when running the following commands.

## Procedure

- Run the **reset rip { process-id| all } configuration** command to reset the configuration parameters of the specific RIP process. When the RIP process is initiated, the default configuration parameters are restored to the default values.
- Run the **reset rip { process-id| all } imported-routes** command to clear the routes imported from other routing protocols and then import these routes into RIP again.
- Run the **reset rip { process-id| all } statistics [ interface interface-type interface-number ]** command to clear the statistics of the counter that is maintained by a particular RIP process. This command helps to re-collect statistics during debugging.

----End

## Debugging RIP

Routers can generate associated debugging information after you enable the debugging of modules in the user view. Debugging information displays the contents of the packets sent or received by the debugged modules.

## Context

### NOTICE

Debugging affects system performance. Therefore, after debugging, run the **undo debugging all** command to disable it immediately.

If a RIP fault occurs, run the **debugging** command in the user view to debug RIP, view the debugging information, and locate and analyze the fault.

## Procedure

- Step 1** Run the **debugging rip process-id packet [ send | receive ] [ error ] [ verbose ] [ interface interface-type interface-number [ peer peer-address ] ]** command to debug the RIP packets sent or received on the network.
- Step 2** Run the **debugging rip process-id route [ error | backup ] [ imported ] { interface interface-type interface-number [ peer peer-address ] } ]** command to debug RIP routes.

**Step 3** Run the **debugging rip miscellaneous** command to debug RIP packets globally.

----End

#### 1.1.6.2.14 Configuration Examples for RIP

This section provides RIP configuration examples.

#### Example for Configuring Basic RIP Functions

This section describes how to configure basic RIP functions, including how to enable RIP and configure a RIP version number on each device.

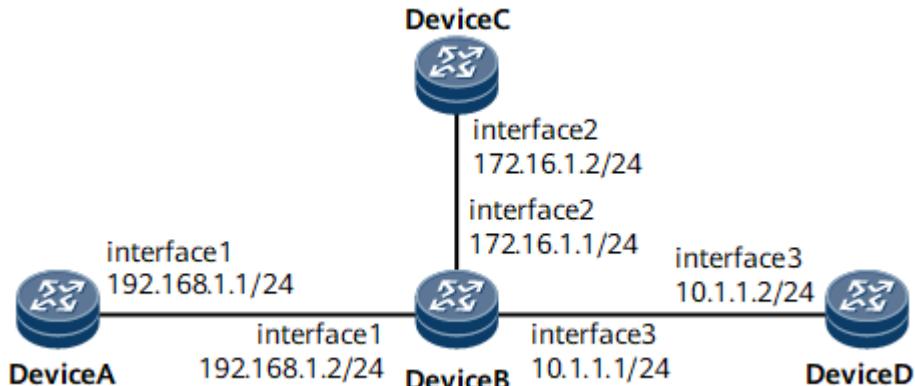

#### Networking Requirements

On the network shown in [Figure 1-211](#), it is required that RIP be enabled on all interfaces of DeviceA, DeviceB, DeviceC, and DeviceD and that these interfaces communicate with each other through RIP-2.

**Figure 1-211** Configuring basic RIP functions

In this example, interface1, interface2, and interface3 represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

#### Precautions

During the configuration, note the following:

- Different network segments on the same physical interface cannot be enabled in different RIP processes.
- If a RIP process is bound to a VPN instance, interfaces in this RIP process also need to be bound to the VPN instance.

#### Configuration Roadmap

The configuration roadmap is as follows:

1. Assign an IP address to each interface to ensure network connectivity.

2. Configure RIP-2 packet authentication.
3. Enable RIP and configure basic RIP functions on each router.
4. Configure RIP-2 on each router and check the subnet mask.

## Data Preparation

To complete the configuration, you need the following data:

- RIP-enabled network segment 192.168.1.0 on DeviceA
- RIP-enabled network segments 192.168.1.0, 172.16.0.0, and 10.0.0.0 on DeviceB
- RIP-enabled network segment 172.16.0.0 on DeviceC
- RIP-enabled network segment 10.0.0.0 on DeviceD
- RIP-2 on DeviceA, DeviceB, DeviceC, and DeviceD

## Procedure

**Step 1** Assign an IP address to each interface. For configuration details, see configuration files in this section.

**Step 2** Configure RIP-2 packet authentication.

# Configure DeviceA.

```
[~DeviceA] interface gigabitethernet1/0/0
[*DeviceA-GigabitEthernet1/0/0] rip authentication-mode hmac-sha256 cipher YsHsjx_202206 200
[*DeviceA-GigabitEthernet1/0/0] commit
[~DeviceA] quit
```

The configurations of other devices are similar to the configuration of DeviceA. For configuration details, see configuration files.

### NOTE

The directly connected interfaces must be configured with the same authentication password. Otherwise, the neighbor relationship cannot be established.

**Step 3** Configure the network segments to be enabled with RIP.

# Configure DeviceA.

```
[~DeviceA] rip
[*DeviceA-rip-1] network 192.168.1.0
[*DeviceA-rip-1] commit
[~DeviceA-rip-1] quit
```

# Configure DeviceB.

```
[~DeviceB] rip
[*DeviceB-rip-1] network 192.168.1.0
[*DeviceB-rip-1] network 172.16.0.0
[*DeviceB-rip-1] network 10.0.0.0
[*DeviceB-rip-1] commit
[~DeviceB-rip-1] quit
```

# Configure DeviceC.

```
[~DeviceC] rip
[*DeviceC-rip-1] network 172.16.0.0
[*DeviceC-rip-1] commit
```

```
[~DeviceC-rip-1] quit

Configure DeviceD.

[~DeviceD] rip
[*DeviceD-rip-1] network 10.0.0.0
[*DeviceD-rip-1] commit
[~DeviceD-rip-1] quit
```

# Check the RIP routing table of DeviceA.

```
[~DeviceA] display rip 1 route
Route Flags: R - RIP
 A - Aging, S - Suppressed, G - Garbage-collect

Peer 192.168.1.2 on GigabitEthernet1/0/0
 Destination/Mask Nexthop Cost Tag Flags Sec
 10.0.0.0/8 192.168.1.2 1 0 RA 14
 172.16.0.0/16 192.168.1.2 1 0 RA 14
```

The command output shows that the routes advertised by RIP-1 use natural masks.

**Step 4** Configure the RIP version number.

# Configure RIP-2 on DeviceA.

```
[~DeviceA] rip
[~DeviceA-rip-1] version 2
[*DeviceA-rip-1] commit
[~DeviceA-rip-1] quit
```

# Configure RIP-2 on DeviceB.

```
[~DeviceB] rip
[~DeviceB-rip-1] version 2
[*DeviceB-rip-1] commit
[~DeviceB-rip-1] quit
```

# Configure RIP-2 on DeviceC.

```
[~DeviceC] rip
[~DeviceC-rip-1] version 2
[*DeviceC-rip-1] commit
[~DeviceC-rip-1] quit
```

# Configure RIP-2 on DeviceD.

```
[~DeviceD] rip
[~DeviceD-rip-1] version 2
[*DeviceD-rip-1] commit
[~DeviceD-rip-1] quit
```

**Step 5** Verify the configuration.

# Check the RIP routing table of DeviceA.

```
[~DeviceA] display rip 1 route
Route Flags: R - RIP
 A - Aging, S - Suppressed, G - Garbage-collect

Peer 192.168.1.2 on GigabitEthernet1/0/0
 Destination/Mask Nexthop Cost Tag Flags Sec
 10.1.1.0/24 192.168.1.2 1 0 RA 32
 172.16.1.0/24 192.168.1.2 1 0 RA 32
```

The command output shows that the routes advertised by RIP-2 contain more accurate subnet masks.

----End

## Example for Preventing Routing Loops

This section describes how to configure split horizon to prevent routing loops.

### Networking Requirements

On the network shown in [Figure 1-212](#), IP addresses have been configured for interfaces on all routers, RIP-2 has been configured on each router, and RIP services are running properly. Classful summarization is enabled on routerA and routerC. It is required that split horizon be configured on routerA and routerC.

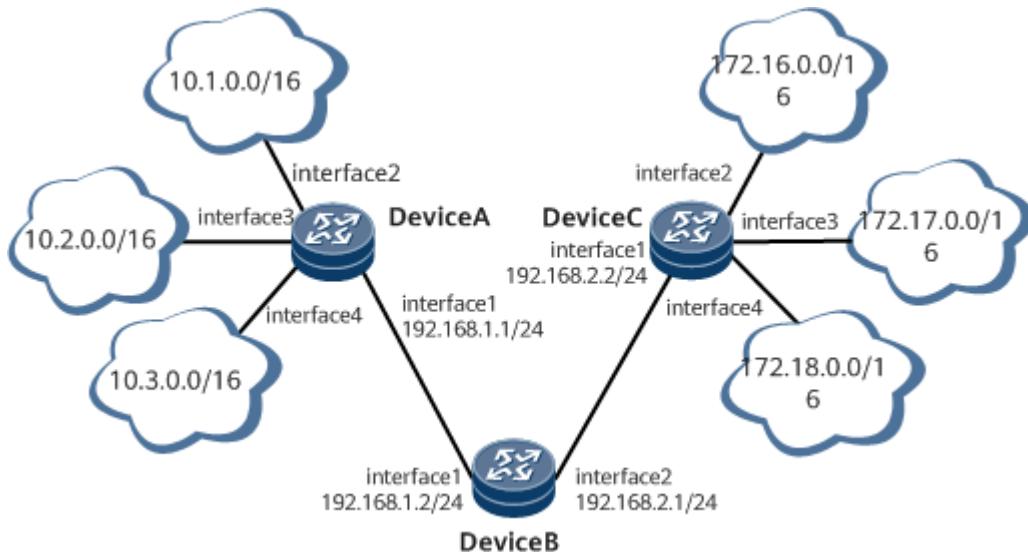

#### NOTE

When configuring classful summarization on a RIP-2 network, you need to disable split horizon and poison reverse. After classful summarization is disabled, you need to reconfigure split horizon or poison reverse to prevent routing loops. This section uses split horizon as an example.

**Figure 1-212** Network diagram of configuring routing loop prevention

#### NOTE

interface1, interface2, interface3, and interface4 in this example represent GE1/0/0, GE1/0/1, GE1/0/2, and GE1/0/3, respectively.

## Precautions

During the configuration, note the following:

If both split horizon and poison reverse are configured, only poison reverse takes effect.

To improve security, you are advised to configure RIP-2 packet authentication. For details, see "Improving RIP Network Security." The following example describes how to configure an authentication mode for RIP-2 packets. For details, see "Example for Configuring Basic RIP Functions."

## Configuration Roadmap

The configuration roadmap is as follows:

1. Disable route summarization.
2. Enable split horizon.

## Data Preparation

To complete the configuration, you need the following data:

- RIP-enabled network segments 10.1.0.0, 10.2.0.0, 10.3.0.0, and 192.168.0.0 on DeviceA
- RIP-enabled network segment 192.168.0.0 on DeviceB
- RIP-enabled network segments 172.16.0.0, 172.17.0.0, 172.18.0.0, and 192.168.0.0 on DeviceC
- IP addresses of interfaces

## Procedure

### Step 1 Disable route summarization.

# Disable route summarization on DeviceA.

```
[~DeviceA] rip 1
```

```
[*DeviceA-rip-1] undo summary
[*DeviceA-rip-1] commit
[~DeviceA-rip-1] quit
```

# Disable route summarization on DeviceB.

```
[~DeviceB] rip 1
[*DeviceB-rip-1] undo summary
[*DeviceB-rip-1] commit
[~DeviceB-rip-1] quit
```

## Step 2 Configure split horizon.

Configure split horizon on the RIP interfaces of all routers. The configurations of DeviceB and DeviceC are similar to the configuration of DeviceA. For details, see configuration files.

# Configure DeviceA.

```
[~DeviceA] interface gigabitethernet1/0/0
[~DeviceA-GigabitEthernet1/0/0] rip split-horizon
[*DeviceA-GigabitEthernet1/0/0] quit
[*DeviceA] interface gigabitethernet1/0/1
[*DeviceA-GigabitEthernet1/0/1] rip split-horizon
[*DeviceA-GigabitEthernet1/0/1] quit
[*DeviceA] interface gigabitethernet1/0/2
[*DeviceA-GigabitEthernet1/0/2] rip split-horizon
[*DeviceA-GigabitEthernet1/0/2] quit
[*DeviceA] interface gigabitethernet1/0/3
[*DeviceA-GigabitEthernet1/0/3] rip split-horizon
[*DeviceA-GigabitEthernet1/0/3] quit
[*DeviceA] commit
```

## Step 3 Verify the configuration.

# Run the **display rip 1 interface verbose** command on DeviceA and DeviceC to check the result after split horizon is configured. Use the command output on DeviceA as an example. If the value of the Split-Horizon field is Enabled, split horizon has been enabled.

```
[~DeviceA] display rip 1 interface verbose

## Example for Configuring RIP to Import Routes

This section describes how to configure RIP to import external routes to increase the number of routes in the RIP routing table.

## Networking Requirements

On the network shown in [Figure 1-213](#), DeviceB runs two RIP processes: RIP 100 and RIP 200. DeviceB exchanges routing information with DeviceA through RIP 100 and with DeviceC through RIP 200.

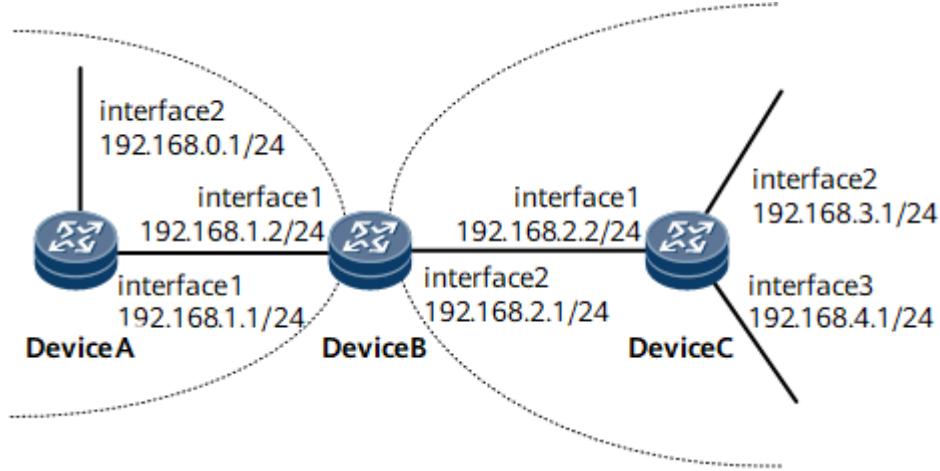

It is required that DeviceB be configured to import routes from two processes to each other and that the default metric of the routes imported from RIP 200 be set to 3.

In addition, a filtering policy needs to be configured on DeviceB to filter out the route 192.168.4.0/24 imported from RIP 200 so that the route is not advertised to DeviceA.

Figure 1-213 Network diagram of configuring RIP to import external routes

 NOTE

In this example, interface1, interface2, and interface3 represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

## Context

Run one of the following commands to set a metric for imported routes. The commands are listed in descending order of priority:

- **apply cost**: sets a route metric.
- **import-route (RIP view)**: sets a metric for imported routes.
- **default-cost (RIP view)**: sets a metric for default routes.

## Precautions

To improve security, you are advised to configure RIP-2 packet authentication. For details, see "Improving RIP Network Security." The following example describes how to configure an authentication mode for RIP-2 packets. For details, see "Example for Configuring Basic RIP Functions."

## Configuration Roadmap

The configuration roadmap is as follows:

1. Enable RIP 100 and RIP 200 on each router and specify network segments.
2. Configure two RIP processes on DeviceB to import routes from each other and set the default metric of the routes imported from RIP 200 to 3.
3. Configure an ACL on DeviceB to filter out the routes imported from RIP 200.

## Data Preparation

To complete the configuration, you need the following data:

- RIP network segments 192.168.0.0 and 192.168.1.0 on DeviceA
- RIP network segments 192.168.1.0 and 192.168.2.0 on DeviceB

- RIP network segments 192.168.2.0, 192.168.3.0, and 192.168.4.0 on DeviceC

## Procedure

**Step 1** Assign an IP address to each interface. For configuration details, see configuration files in this section.

**Step 2** Configure basic RIP functions.

# Enable RIP process 100 on DeviceA.

```
[~DeviceA] rip 100
[*DeviceA-rip-100] network 192.168.0.0
[*DeviceA-rip-100] network 192.168.1.0
[*DeviceA-rip-100] commit
[~DeviceA-rip-100] quit
```

# Enable RIP 100 and RIP 200 on DeviceB.

```
[~DeviceB] rip 100
[*DeviceB-rip-100] network 192.168.1.0
[*DeviceB-rip-100] quit
[*DeviceB] rip 200
[*DeviceB-rip-200] network 192.168.2.0
[*DeviceB-rip-200] commit
[~DeviceB-rip-200] quit
```

# Enable RIP process 200 on DeviceC.

```
[~DeviceC] rip 200
[*DeviceC-rip-200] network 192.168.2.0
[*DeviceC-rip-200] network 192.168.3.0
[*DeviceC-rip-200] network 192.168.4.0
[*DeviceC-rip-200] commit
[~DeviceC-rip-200] quit
```

# Check the routing table of DeviceA.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: _public_
Destinations : 7 Routes : 7
Destination/Mask Proto Pre Cost Flags NextHop Interface
 127.0.0.0/8 Direct 0 0 D 127.0.0.1 InLoopBack0
 127.0.0.1/32 Direct 0 0 D 127.0.0.1 InLoopBack0
 192.168.0.0/24 Direct 0 0 D 192.168.0.1 GigabitEthernet2/0/0
 192.168.0.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet2/0/0
 192.168.1.0/24 Direct 0 0 D 192.168.1.1 GigabitEthernet1/0/0
 192.168.1.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet1/0/0
 192.168.1.2/32 Direct 0 0 D 192.168.1.2 GigabitEthernet1/0/0
```

The command output shows that the routing table of DeviceA does not contain the routes of other processes.

**Step 3** Configure RIP to import external routes.

# Set the default route metric to 3 on DeviceB and import routes of the two RIP processes into the routing table of each other.

```
[~DeviceB] rip 100
[*DeviceB-rip-100] default-cost 3
[*DeviceB-rip-100] import-route rip 200
[*DeviceB-rip-100] quit
[*DeviceB] rip 200
[*DeviceB-rip-200] import-route rip 100
[*DeviceB-rip-200] quit
```

[\*DeviceB] **commit**

# Check the routing table of DeviceA after the routes are imported.

[~DeviceA] **display ip routing-table**

Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: \_public\_

Destinations : 10 Routes : 10

| Destination/Mask      | Proto  | Pre | Cost | Flags | NextHop            | Interface                   |
|-----------------------|--------|-----|------|-------|--------------------|-----------------------------|
| 127.0.0.0/8           | Direct | 0   | 0    | D     | 127.0.0.1          | InLoopBack0                 |
| 127.0.0.1/32          | Direct | 0   | 0    | D     | 127.0.0.1          | InLoopBack0                 |
| 192.168.0.0/24        | Direct | 0   | 0    | D     | 192.168.0.1        | GigabitEthernet2/0/0        |
| 192.168.0.1/32        | Direct | 0   | 0    | D     | 127.0.0.1          | GigabitEthernet2/0/0        |
| 192.168.1.0/24        | Direct | 0   | 0    | D     | 192.168.1.1        | GigabitEthernet1/0/0        |
| 192.168.1.1/32        | Direct | 0   | 0    | D     | 127.0.0.1          | GigabitEthernet1/0/0        |
| 192.168.1.2/32        | Direct | 0   | 0    | D     | 192.168.1.2        | GigabitEthernet1/0/0        |
| <b>192.168.2.0/24</b> | RIP    | 100 | 4    | D     | <b>192.168.1.2</b> | <b>GigabitEthernet1/0/0</b> |
| 192.168.3.0/24        | RIP    | 100 | 4    | D     | 192.168.1.2        | GigabitEthernet1/0/0        |
| 192.168.4.0/24        | RIP    | 100 | 4    | D     | 192.168.1.2        | GigabitEthernet1/0/0        |

The RIP routing table of DeviceA contains routes 192.168.2.0/24, 192.168.3.0/24, and 192.168.3.0/24. These new routes are learned from RIP process 200 on DeviceB.

#### Step 4 Configure RIP to filter imported routes.

# Configure an ACL on DeviceB and set a rule to deny the packets with source address 192.168.4.0/24.

[~DeviceB] **acl 2000**

[\*DeviceB-acl4-basic-2000] **rule deny source 192.168.4.0 0.0.0.255**

[\*DeviceB-acl4-basic-2000] **rule permit**

[\*DeviceB-acl4-basic-2000] **quit**

# On DeviceB, filter out the route 192.168.4.0/24 imported from RIP 200 according to the ACL rule.

[\*DeviceB] **rip 100**

[\*DeviceB-rip-100] **filter-policy 2000 export**

[\*DeviceB-rip-100] **quit**

[\*DeviceB] **commit**

#### Step 5 Verify the configuration.

# Check the routing table of DeviceA after the filtering.

[~DeviceA] **display ip routing-table**

Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table: \_public\_

Destinations : 9 Routes : 9

| Destination/Mask | Proto  | Pre | Cost | Flags | NextHop     | Interface            |
|------------------|--------|-----|------|-------|-------------|----------------------|
| 127.0.0.0/8      | Direct | 0   | 0    | D     | 127.0.0.1   | InLoopBack0          |
| 127.0.0.1/32     | Direct | 0   | 0    | D     | 127.0.0.1   | InLoopBack0          |
| 192.168.0.0/24   | Direct | 0   | 0    | D     | 192.168.0.1 | GigabitEthernet2/0/0 |
| 192.168.0.1/32   | Direct | 0   | 0    | D     | 127.0.0.1   | GigabitEthernet2/0/0 |
| 192.168.1.0/24   | Direct | 0   | 0    | D     | 192.168.1.1 | GigabitEthernet1/0/0 |
| 192.168.1.1/32   | Direct | 0   | 0    | D     | 127.0.0.1   | GigabitEthernet1/0/0 |
| 192.168.1.2/32   | Direct | 0   | 0    | D     | 192.168.1.2 | GigabitEthernet1/0/0 |
| 192.168.2.0/24   | RIP    | 100 | 4    | D     | 192.168.1.2 | GigabitEthernet1/0/0 |
| 192.168.3.0/24   | RIP    | 100 | 4    | D     | 192.168.1.2 | GigabitEthernet1/0/0 |

The command output shows that the RIP routing table of DeviceA changes. That is, the route with the source address 192.168.4.0/24 is denied.

----End

## Example for Configuring Dynamic BFD for RIP

This section describes how to configure dynamic BFD on a RIP network to rapidly detect link faults and notify RIP of the faults to trigger service traffic switchover.

## Networking Requirements

RIP periodically exchanges Update messages to monitor the status of neighbors. By default, if a local device does not receive any Update messages from its neighbor after six update intervals (180s) elapse, it considers the neighbor down.

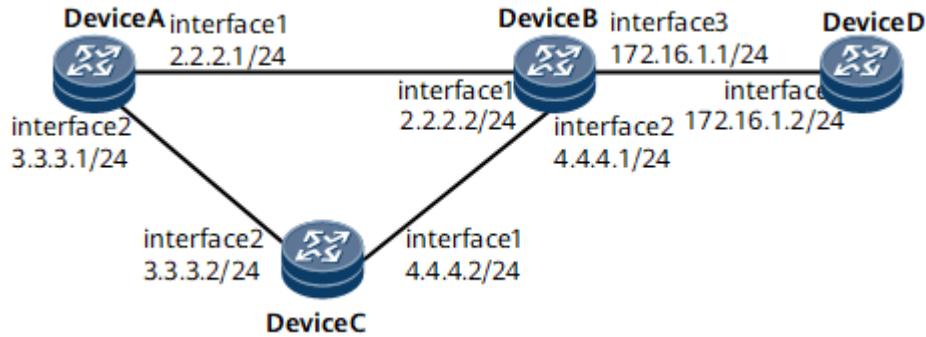

Voice, video, and other VOD services are widely used and are sensitive to the packet loss and delay. Long-time fault detection will cause the loss of a large number of data packets. As a result, the requirement of carrier-class networks for high reliability cannot be met. BFD for RIP can be deployed to complete link fault detection within milliseconds, speeding up RIP convergence.

On the network shown in [Figure 1-214](#), primary and backup links are deployed. The primary link is Device A -> Device B, and the backup link is Device A -> Device C -> Device B. In normal cases, service traffic is transmitted along the primary link. If the primary link fails, it is expected that the fault is rapidly detected and that service traffic is switched to the backup link in time. In this case, you can configure BFD for RIP to monitor the RIP neighbor relationship between DeviceA and DeviceB. If the link between DeviceA and DeviceB fails, BFD can rapidly detect the fault and notify RIP of the fault. Then service traffic is switched to the backup link for transmission.

**Figure 1-214** Network diagram of configuring dynamic BFD for RIP

### NOTE

In this example, interface1, interface2, and interface3 represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

## Precautions

To improve security, you are advised to configure RIP-2 packet authentication. For details, see "Improving RIP Network Security." The following example describes how to configure an authentication mode for RIP-2 packets. For details, see "Example for Configuring Basic RIP Functions."

## Configuration Roadmap

The configuration roadmap is as follows:

1. Enable basic RIP functions on each router and ensure that RIP neighbor relationships are established.
2. Enable global BFD.
3. Enable BFD on the interfaces of the link between DeviceA and DeviceB.

## Data Preparation

To complete the configuration, you need the following data:

- DeviceA: RIP process ID (1), RIP version number (2), IP address of GE 1/0/0 (2.2.2.1/24), and IP address of GE 2/0/0 (3.3.3.1/24)
- DeviceB: RIP process ID (1), RIP version number (2), IP address of GE 1/0/0 (2.2.2.2/24), IP address of GE 2/0/0 (4.4.4.1/24), and IP address of GE 3/0/0 (172.16.1.1/24)
- DeviceC: RIP process ID (1), RIP version number (2), IP address of GE 1/0/0 (4.4.4.2/24), and IP address of GE 2/0/0 (3.3.3.2/24)
- DeviceD: RIP process ID (1), RIP version number (2), and IP address of GE 1/0/0 (172.16.1.2/24)
- Minimum interval at which BFD packets are sent (100 ms), minimum interval at which BFD packets are received (100 ms), and local detection multiplier (10) on DeviceA and DeviceB

## Procedure

### Step 1 Configure IP addresses for interfaces.

Assign an IP address to each interface according to [Figure 1-214](#) and [Data Preparation](#). For configuration details, see configuration files in this section.

### Step 2 Configure basic RIP functions.

# Configure DeviceA.

```
<DeviceA> system-view
[~DeviceA] rip 1
[*DeviceA-rip-1] version 2
[*DeviceA-rip-1] network 2.0.0.0
[*DeviceA-rip-1] network 3.0.0.0
[*DeviceA-rip-1] commit
[~DeviceA-rip-1] quit
```

# Configure DeviceB.

```
<DeviceB> system-view
[~DeviceB] rip 1
[*DeviceB-rip-1] version 2
[*DeviceB-rip-1] network 2.0.0.0
[*DeviceB-rip-1] network 4.0.0.0
[*DeviceB-rip-1] network 172.16.0.0
[*DeviceB-rip-1] commit
[~DeviceB-rip-1] quit
```

# Configure DeviceC.

```
<DeviceC> system-view
```

```
[~DeviceC] rip 1
[*DeviceC-rip-1] version 2
[*DeviceC-rip-1] network 3.0.0.0
[*DeviceC-rip-1] network 4.0.0.0
[*DeviceC-rip-1] commit
[~DeviceC-rip-1] quit
```

# Configure DeviceD.

```
<DeviceD> system-view
[~DeviceD] rip 1
[*DeviceD-rip-1] version 2
[*DeviceD-rip-1] network 172.16.0.0
[*DeviceD-rip-1] commit
[~DeviceD-rip-1] quit
```

# After completing the preceding configurations, run the **display rip neighbor** command. The command output shows that DeviceA has established neighbor relationships with DeviceB and DeviceC. Use the command output on DeviceA as an example.

```
[~DeviceA] display rip 1 neighbor
```

| IP Address              | Interface Type       | Type | Last-Heard-Time |
|-------------------------|----------------------|------|-----------------|
| 3.3.3.2                 | GigabitEthernet2/0/0 | RIP  | 0:0:5           |
| Number of RIP routes :2 |                      |      |                 |
| 2.2.2.2                 | GigabitEthernet1/0/0 | RIP  | 0:0:5           |
| Number of RIP routes :4 |                      |      |                 |

# Run the **display ip routing-table** command. The command output shows that routers can import routes from each other. Take the command output on DeviceA as an example.

```
[~DeviceA] display ip routing-table
```

```
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route
```

```
Routing Table : _public_
Destinations : 15 Routes : 15
```

| Destination/Mask   | Proto  | Pre | Cost | Flags | NextHop   | Interface            |
|--------------------|--------|-----|------|-------|-----------|----------------------|
| 3.0.0.0/8          | RIP    | 100 | 3    | D     | 3.3.3.2   | GigabitEthernet2/0/0 |
| 3.3.3.0/24         | Direct | 0   | 0    | D     | 3.3.3.1   | GigabitEthernet2/0/0 |
| 3.3.3.1/32         | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet2/0/0 |
| 3.3.3.255/32       | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet2/0/0 |
| 2.0.0.0/8          | RIP    | 100 | 3    | D     | 2.2.2.2   | GigabitEthernet1/0/0 |
| 2.2.2.0/24         | Direct | 0   | 0    | D     | 2.2.2.1   | GigabitEthernet1/0/0 |
| 2.2.2.1/32         | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet1/0/0 |
| 2.2.2.255/32       | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet1/0/0 |
| 127.0.0.0/8        | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 127.0.0.1/32       | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 127.255.255.255/32 | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 172.16.0.0/16      | RIP    | 100 | 4    | D     | 2.2.2.2   | GigabitEthernet1/0/0 |
| 172.16.1.0/24      | RIP    | 100 | 1    | D     | 2.2.2.2   | GigabitEthernet1/0/0 |
| 4.4.4.0/24         | RIP    | 100 | 1    | D     | 3.3.3.2   | GigabitEthernet2/0/0 |
|                    | RIP    | 100 | 1    | D     | 2.2.2.2   | GigabitEthernet1/0/0 |
| 255.255.255.255/32 | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |

The routing table shows that the next-hop address of the route destined for 172.16.1.0/24 is 2.2.2.2 and that the outbound interface is GigabitEthernet 1/0/0. This indicates that traffic is transmitted on the primary link DeviceA -> DeviceB.

### Step 3 Configure BFD for RIP.

# Configure BFD on all interfaces of DeviceA.

```
[~DeviceA] bfd
```

```
[*DeviceA-bfd] quit
[*DeviceA] rip 1
[*DeviceA-rip-1] bfd all-interfaces enable
[*DeviceA-rip-1] bfd all-interfaces min-rx-interval 100 min-tx-interval 100 detect-multiplier 10
[*DeviceA-rip-1] commit
[~DeviceA-rip-1] quit
```

The configuration on DeviceB is similar to the preceding configuration. For details, see configuration files.

# After completing the configurations, run the **display rip bfd session** command. The command output shows that a BFD session has been established between DeviceA and DeviceB and that the BFD State is Up. Use the command output on DeviceA as an example.

```
[~DeviceA] display rip 1 bfd session all
Interface :GigabitEthernet1/0/0
Locallp :2.2.2.1 Remotelp :2.2.2.2 BFDState :Up

Interface :GigabitEthernet2/0/0
Locallp :3.3.3.1 Remotelp :3.3.3.2 BFDState :Down
```

#### Step 4 Verifying the Configuration

# Run the **shutdown** command on GigabitEthernet 1/0/0 of DeviceB to simulate a fault on the primary link.

Link fault simulation is required for verification and does not need to be performed in actual applications.

```
[~DeviceB] interface gigabitethernet1/0/0
[~DeviceB-GigabitEthernet1/0/0] shutdown
[*DeviceB-GigabitEthernet1/0/0] commit
```

# Check information about the BFD session on DeviceA. The command output shows that no BFD session exists between DeviceA and DeviceB.

```
[~DeviceA] display rip 1 bfd session all
Interface :GigabitEthernet2/0/0
Locallp :3.3.3.1 Remotelp :3.3.3.2 BFDState :Down
```

# Check the routing table of DeviceA.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
Destinations : 8 Routes : 8
Destination/Mask Proto Pre Cost Flags NextHop Interface
3.3.3.0/24 Direct 0 0 D 3.3.3.1 GigabitEthernet2/0/0
3.3.3.1/32 Direct 0 0 D 127.0.0.1 GigabitEthernet2/0/0
3.3.3.255/32 Direct 0 0 D 127.0.0.1 GigabitEthernet2/0/0
127.0.0.0/8 Direct 0 0 D 127.0.0.1 InLoopBack0
127.0.0.1/32 Direct 0 0 D 127.0.0.1 InLoopBack0
127.255.255.255/32 Direct 0 0 D 127.0.0.1 InLoopBack0
172.16.1.0/24 RIP 100 2 D 3.3.3.2 GigabitEthernet2/0/0
255.255.255.255/32 Direct 0 0 D 127.0.0.1 InLoopBack0
```

The routing table shows that the backup link DeviceA -> DeviceC -> DeviceB is used after the primary link fails. The next hop address of the route to 172.16.1.0/24 is 3.3.3.2, and the outbound interface is GigabitEthernet 2/0/0.

----End

## Configuration Files

- DeviceA configuration file

```

sysname DeviceA

## Example for Configuring Static BFD for RIP

This section provides an example for configuring static BFD for RIP.

## Networking Requirements

RIP periodically exchanges Update messages to monitor the status of neighbors. By default, if a local device does not receive any Update messages from its neighbor after six update intervals (180s) elapse, it considers the neighbor down.

Voice, video, and other VOD services are widely used and are sensitive to the packet loss and delay. Long-time fault detection will cause the loss of a large number of data packets. As a result, the requirement of carrier-class networks for high reliability cannot be met. BFD for RIP can be deployed to complete link fault detection within milliseconds, speeding up RIP convergence.

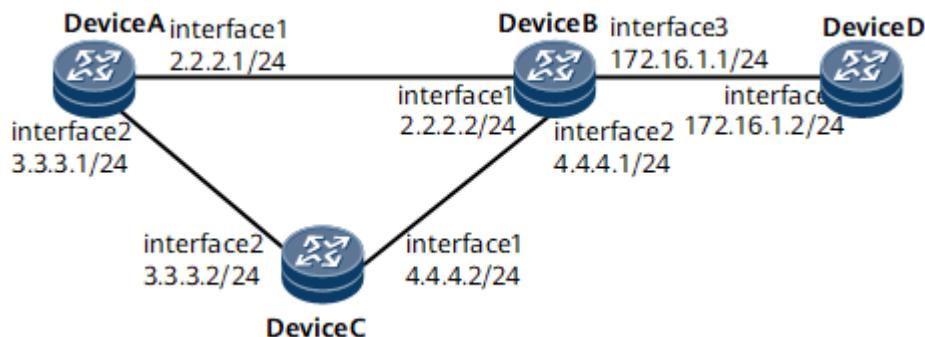

On the network shown in [Figure 1-215](#):

- DeviceA, DeviceB, DeviceC, and DeviceD run RIP.
- Traffic is transmitted along the primary link DeviceA -> DeviceB -> DeviceD. Static BFD is enabled on the interfaces connecting DeviceA and DeviceB. If the primary link fails, BFD can rapidly detect the fault and notify RIP of the fault, allowing service traffic to be rapidly switched to the backup link.

**Figure 1-215** Configuring static BFD for RIP

In this example, interface1, interface2, and interface3 represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

## Precautions

To improve security, you are advised to configure RIP-2 packet authentication. For details, see "Improving RIP Network Security." The following example describes how to configure an authentication mode for RIP-2 packets. For details, see "Example for Configuring Basic RIP Functions."

## Configuration Roadmap

The configuration roadmap is as follows:

1. Configure basic RIP functions on each router to establish RIP neighbor relationships.
2. Enable BFD globally.
3. Enable static BFD on the interfaces connecting DeviceA and DeviceB.

## Data Preparation

To complete the configuration, you need the following data:

- DeviceA: RIP process ID (1), RIP version number (2), IP address of GE 1/0/0 (2.2.2.1/24), and IP address of GE 2/0/0 (3.3.3.1/24)
- DeviceB: RIP process ID (1), RIP version number (2), and IP addresses of GE 1/0/0, GE 2/0/0, and GE3/0/0 (2.2.2.2/24, 4.4.4.1/24, and 172.16.1.1/24, respectively)
- DeviceC: RIP process ID (1), RIP version number (2), IP address of GE 1/0/0 (4.4.4.2/24), and IP address of GE 2/0/0 (3.3.3.2/24)
- DeviceD: RIP process ID (1), RIP version number (2), and IP address of GE 1/0/0 (172.16.1.2/24)
- Local and remote discriminators of the BFD session established between DeviceA and DeviceB

## Procedure

### Step 1 Configure IP addresses for interfaces.

Assign an IP address to each interface according to [Figure 1-215](#) and [Data Preparation](#). For configuration details, see configuration files in this section.

### Step 2 Configure basic RIP functions.

# Configure DeviceA.

```
<DeviceA> system-view
[~DeviceA] rip 1
[*DeviceA-rip-1] version 2
[*DeviceA-rip-1] network 2.0.0.0
[*DeviceA-rip-1] network 3.0.0.0
[*DeviceA-rip-1] commit
[~DeviceA-rip-1] quit
```

# Configure DeviceB.

```
<DeviceB> system-view
[~DeviceB] rip 1
[*DeviceB-rip-1] version 2
[*DeviceB-rip-1] network 2.0.0.0
```

```
[*DeviceB-rip-1] network 4.0.0.0
[*DeviceB-rip-1] network 172.16.0.0
[*DeviceB-rip-1] commit
[~DeviceB-rip-1] quit
```

# Configure DeviceC.

```
<DeviceC> system-view
[~DeviceC] rip 1
[*DeviceC-rip-1] version 2
[*DeviceC-rip-1] network 3.0.0.0
[*DeviceC-rip-1] network 4.0.0.0
[*DeviceC-rip-1] commit
[~DeviceC-rip-1] quit
```

# Configure DeviceD.

```
<DeviceD> system-view
[~DeviceD] rip 1
[*DeviceD-rip-1] version 2
[*DeviceD-rip-1] network 172.16.0.0
[*DeviceD-rip-1] commit
[~DeviceD-rip-1] quit
```

# After completing the preceding configurations, run the **display rip neighbor** command. The command output shows that DeviceA has established neighbor relationships with DeviceB and DeviceC. Use the command output on DeviceA as an example.

```
[~DeviceA] display rip 1 neighbor
```

| IP Address              | Interface            | Type | Last-Heard-Time |
|-------------------------|----------------------|------|-----------------|
| 3.3.3.2                 | GigabitEthernet2/0/0 | RIP  | 0:0:5           |

| 2.2.2.0/24         | Direct | 0   | 0    | D     | 2.2.2.1   | GigabitEthernet1/0/0 |
| 2.2.2.1/32         | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet1/0/0 |
| 2.2.2.255/32       | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet1/0/0 |
| 127.0.0.0/8        | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 127.0.0.1/32       | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 127.255.255.255/32 | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 172.16.0.0/16      | RIP    | 100 | 4    | D     | 2.2.2.2   | GigabitEthernet1/0/0 |
| 172.16.1.0/24      | RIP    | 100 | 1    | D     | 2.2.2.2   | GigabitEthernet1/0/0 |
| 4.4.4.0/24         | RIP    | 100 | 1    | D     | 3.3.3.2   | GigabitEthernet2/0/0 |
|                    | RIP    | 100 | 1    | D     | 2.2.2.2   | GigabitEthernet1/0/0 |
| 255.255.255.255/32 | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |

The routing table shows that the next-hop address of the route destined for 172.16.0.0/16 is 2.2.2.2 and that the outbound interface is GigabitEthernet 1/0/0. This indicates that traffic is transmitted on the primary link DeviceA -> DeviceB.

**Step 3** Configure static BFD.

# Configure static BFD on DeviceA.

```
[~DeviceA] bfd
[*DeviceA-bfd] quit
[*DeviceA] bfd 1 bind peer-ip 2.2.2.2 interface gigabitethernet1/0/0 source-ip 2.2.2.1
[*DeviceA-bfd-session-1] discriminator local 1
[*DeviceA-bfd-session-1] discriminator remote 2
[*DeviceA-bfd-session-1] commit
[~DeviceA-bfd-session-1] quit
[~DeviceA] interface gigabitethernet1/0/0
[~DeviceA-GigabitEthernet1/0/0] rip bfd static
```

# Configure static BFD on DeviceB.

```
[~DeviceB] bfd
[*DeviceB-bfd] quit
[*DeviceB] bfd 1 bind peer-ip 2.2.2.1 interface gigabitethernet1/0/0 source-ip 2.2.2.2
[*DeviceB-bfd-session-1] discriminator local 2
[*DeviceB-bfd-session-1] discriminator remote 1
[*DeviceB-bfd-session-1] commit
[~DeviceB-bfd-session-1] quit
[~DeviceB] interface gigabitethernet1/0/0
[~DeviceB-GigabitEthernet1/0/0] rip bfd static
```

# After completing the configurations, run the **display bfd session all** command on DeviceA. The command output shows that a static BFD session has been established.

```
[~DeviceA] display bfd session all
(w): State in WTR
(*) : State is invalid
```

| Local | Remote | PeerIpAddr | State | Type    | InterfaceName        |
|-------|--------|------------|-------|---------|----------------------|
| 1     | 2      | 2.2.2.2    | Up    | S_IP_IF | GigabitEthernet1/0/0 |

```
Total UP/DOWN Session Number : 1/0
```

**Step 4** Verifying the Configuration

# Run the **shutdown** command on GigabitEthernet 1/0/0 of DeviceB to simulate a fault on the primary link.

 **NOTE**

Link fault simulation is required for verification and does not need to be performed in actual applications.

```
[~DeviceB] interface gigabitethernet1/0/0
[~DeviceB-GigabitEthernet1/0/0] shutdown
[*DeviceB-GigabitEthernet1/0/0] commit
```

# Check information about the BFD session on DeviceA. The command output shows that no BFD session exists between DeviceA and DeviceB.

# Check the routing table of DeviceA.

```
[~DeviceA] display ip routing-table
Route Flags: R - relay, D - download to fib, T - to vpn-instance, B - black hole route

Routing Table : _public_
```

| Destinations : 8      Routes : 8 |        |     |      |       |           |                      |
|----------------------------------|--------|-----|------|-------|-----------|----------------------|
| Destination/Mask                 | Proto  | Pre | Cost | Flags | NextHop   | Interface            |
| 3.3.3.0/24                       | Direct | 0   | 0    | D     | 3.3.3.1   | GigabitEthernet2/0/0 |
| 3.3.3.1/32                       | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet2/0/0 |
| 3.3.3.255/32                     | Direct | 0   | 0    | D     | 127.0.0.1 | GigabitEthernet2/0/0 |
| 127.0.0.0/8                      | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 127.0.0.1/32                     | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 127.255.255.255/32               | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |
| 172.16.1.0/24                    | RIP    | 100 | 2    | D     | 3.3.3.2   | GigabitEthernet2/0/0 |
| 255.255.255.255/32               | Direct | 0   | 0    | D     | 127.0.0.1 | InLoopBack0          |

The routing table shows that the backup link DeviceA -> DeviceC -> DeviceB is used after the primary link fails. The next hop address of the route to 172.16.1.0/24 is 3.3.3.2, and the outbound interface is GigabitEthernet 2/0/0.

----End

## 1.1.7 RIPng Configuration

### 1.1.7.1 RIPng Description

#### 1.1.7.1.1 Overview of RIPng

##### Definition

RIP next generation (RIPng) is an extension to RIP version 2 (RIP-2) on IPv6 networks. Most RIP concepts apply to RIPng.

RIPng is a distance-vector routing protocol, which measures the distance (metric or cost) to the destination host by the hop count. In RIPng, the hop count from a device to its directly connected network is 0, and the hop count from a device to a network that is reachable through another device is 1. When the hop count is equal to or exceeds 16, the destination network or host is defined as unreachable.

To be applied on IPv6 networks, RIPng makes the following changes to RIP:

- UDP port number: RIPng uses UDP port number 521 to send and receive routing information.
- Multicast address: RIPng uses FF02::9 as the link-local multicast address of a RIPng device.
- Prefix length: RIPng uses a 128-bit (the mask length) prefix in the destination address.
- Next hop address: RIPng uses a 128-bit IPv6 address.
- Source address: RIPng uses link-local address FE80::/10 as the source address to send RIPng Update packets.

## Purpose

RIPng is an extension to RIP for support of IPv6.

### 1.1.7.1.2 Understanding RIPng

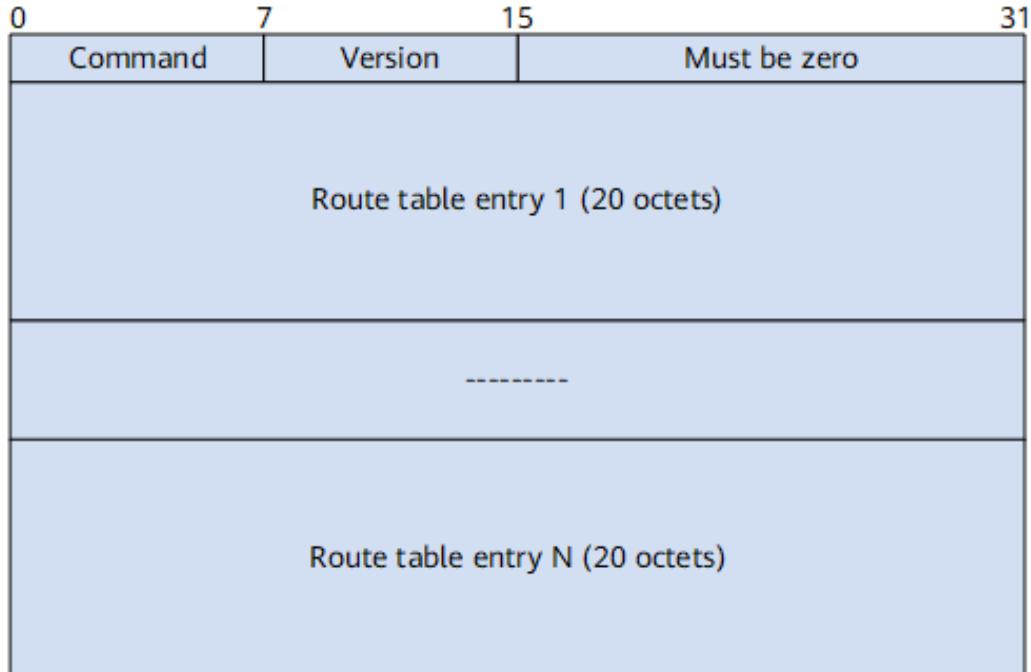

RIPng is an extension to RIPv2 on IPv6 networks and uses the same timers as RIPv2. RIPng supports split horizon, poison reverse, and triggered update, which prevents routing loops.

## RIPng Packet Format

A RIPng packet is composed of a header and multiple route table entries (RTEs). In a RIPng packet, the maximum number of RTEs is determined by the maximum transmission unit (MTU) of an interface.

[Figure 1-216](#) shows the basic format of a RIPng packet.

**Figure 1-216** RIPng packet format

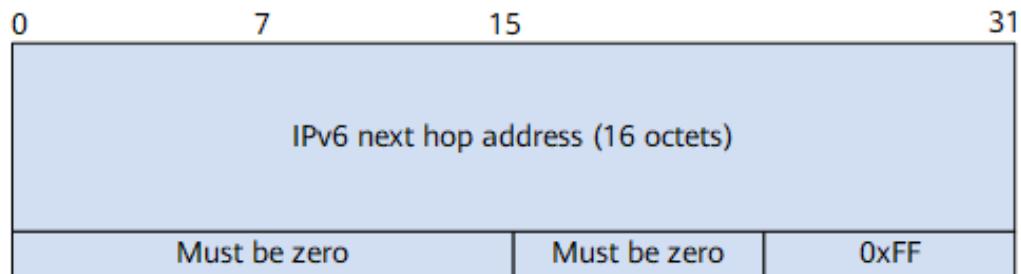

A RIPng packet contains two types of RTEs:

- Next hop RTE: It defines the IPv6 address of the next hop and is located before a group of IPv6-prefix RTEs that have the same next hop. The Metric field of a next hop RTE is always 0xFF.
- IPv6-prefix RTE: It describes the destination IPv6 address and the cost in the RIPng routing table and is located after a next hop RTE. A next hop RTE can be followed by multiple different IPv6-prefix RTEs.

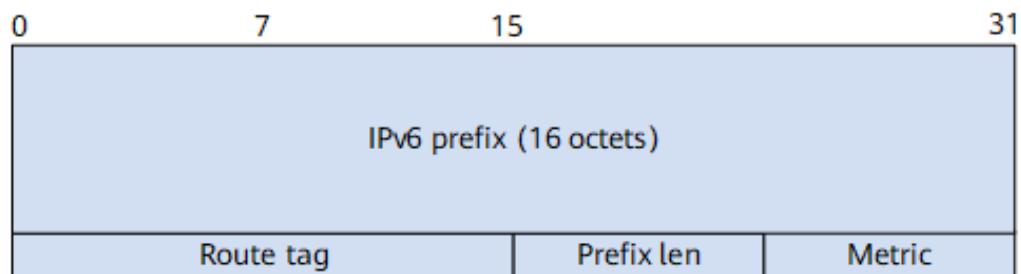

[Figure 1-217](#) shows the format of a next hop RTE.

**Figure 1-217** Format of the next hop RTE

[Figure 1-218](#) shows the format of an IPv6-prefix RTE.

**Figure 1-218** Format of the IPv6-prefix RTE

## Timers

RIPng uses the following timers:

- Update timer: This timer periodically triggers Update packet transmission. By default, the interval at which Update packets are sent is 30s. This timer is used to synchronize RIPng routes on the network.
- Age timer: If a RIPng device does not receive any Update packet from its neighbor before a route expires, the RIPng device considers the route to its neighbor unreachable.
- Garbage-collect timer: If no packet is received to update an unreachable route after the Age timer expires, this route is deleted from the RIPng routing table.

- Hold-down timer: If a RIP device receives an updated route with cost 16 from a neighbor, the route enters the holddown state, and the hold-down timer is started.

The following describes the relationship among these timers:

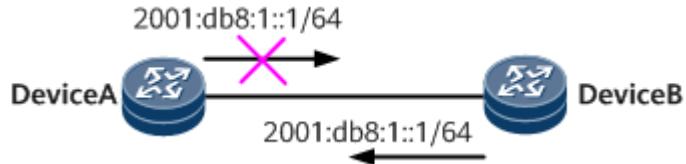

The advertisement of RIPng routing updates is periodically triggered by the update timer with default value 30 seconds. Each routing entry is associated with two timers: the Age timer and garbage-collect timer. Each time a route is learned and added to the routing table, the Age timer is started. If no Update packet is received from the neighbor within 180 seconds, the metric of the route is set to 16, and the garbage-collect timer is started. If no Update packet is received within 120 seconds, the route is deleted after the garbage-collect timer expires.

By default, hold-down timer is disabled. If you configure a hold-down timer, it starts after the system receives a route with a cost greater than 16 from its neighbor.

## Split Horizon

Split horizon prevents a RIPng-enabled interface from sending back the routes it learns, which reduces bandwidth consumption and prevents routing loops.

**Figure 1-219** Networking for split horizon

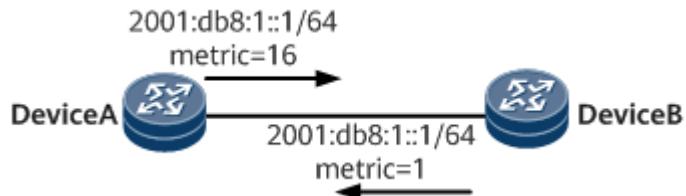

On the network shown in [Figure 1-219](#), after DeviceB sends a route to network 2001:db8:1::1 to DeviceA, DeviceA does not send the route back to DeviceB.

## Poison Reverse

Poison reverse allows a RIPng-enabled interface to set the cost of the route that it learns from a neighbor to 16 (indicating that the route is unreachable) and then send the route back. After receiving this route, the neighbor deletes the useless route from its routing table.

Poison reverse of RIPng can also prevent routing loops.

**Figure 1-220** Networking for poison reverse

In [Figure 1-220](#), if split horizon is not configured, DeviceB sends the route learned from DeviceA back. The cost of the route from DeviceA to network 2001:db8:1::1/64 is 1. If this route becomes unreachable and DeviceB does not

receive any Update packet from DeviceA, DeviceB keeps sending the route destined for 2001:db8:1::1/64 to DeviceA. As a result, a routing loop occurs.

If DeviceA sends a route unreachability message to DeviceB after receiving a route from DeviceB, DeviceB no longer learns the reachable route from DeviceA. This prevents a routing loop.

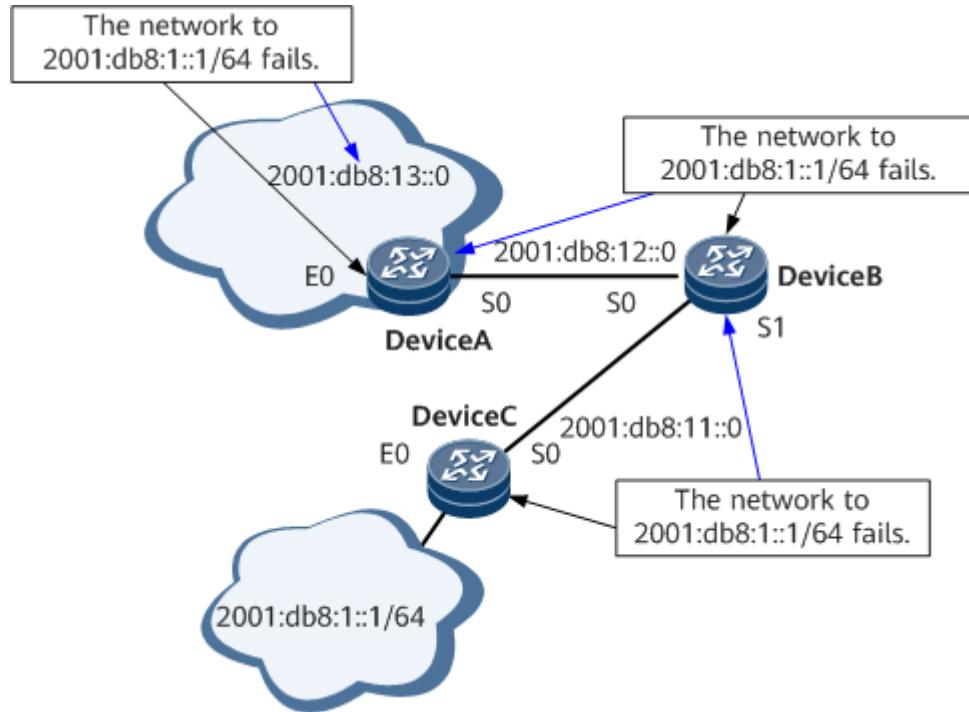

If both split horizon (preventing the routes learned by an interface from being sent back through this interface) and poison reverse are configured, only poison reverse takes effect.

## Triggered Update

Triggered update means that when routing information changes, a device immediately notifies its neighboring devices of the change through triggered update messages.

Triggered update allows a device to immediately broadcast each routing entry change to other devices without waiting for periodic update. This shortens the network convergence time.

**Figure 1-221** Networking for triggered update

In **Figure 1-221**, if network 2001:db8:1::1/64 becomes unreachable, DeviceC learns the information first. Generally, updated routing information is sent to neighboring Devices periodically. For example, RIPng sends the route update message every 30s. If the Update message from DeviceB reaches DeviceC when DeviceC is still waiting for the next round of periodic update, DeviceC learns the incorrect route to 2001:db8:1::1/64 from DeviceB. In this case, the next hops of the routes from DeviceB and DeviceC to network 2001:db8:1::1/64 are DeviceC and DeviceB, respectively. This results in a routing loop. If DeviceC sends an Update message to DeviceB immediately when detecting the network fault, DeviceB can update its routing table in time. This prevents the preceding problem.

Another method of implementing triggered update is as follows: When the next hop of a route becomes unavailable, due to a link failure for example, the local router sets the cost of the route to 16 and then advertises the route immediately to its neighbors. This process is called route poisoning.

## Route Summarization

### Context

On large-scale networks, the RIPng routing table of each device contains a large number of routing entries, which consumes lots of system resources. In addition, if a link within an IP address range frequently alternates between up and down, route flapping occurs.

RIPng route summarization was introduced to address these problems, enabling a device to summarize routes destined for different subnets of a network segment into one route destined for one network segment and then advertise the summary route to other network segments. RIPng route summarization reduces the number of routes in the routing table, minimizes system resource consumption, and prevents route flapping.

### Implementation

RIPng route summarization is implemented on interfaces. After RIPng route summarization is enabled on an interface, the interface summarizes routes based on the longest match rule and the metric of the summary route is the minimum metric among all the original routes.

For example, RIPng can advertise two routes, 2001:db8:1::1 (metric = 2) and 2001:db8:2::1 (metric = 3), through an interface. After route summarization is configured on the interface, the two routes are summarized into one route 2001:DB8::/32 (metric = 2), and this summary route is advertised.

### Multi-Process and Multi-Instance

RIPng supports multi-process and multi-instance, which simplifies network management and improves service control efficiency. Multi-process allows a set of interfaces to be associated with a specific RIPng process, which ensures that the specific RIPng process performs all the protocol operations only on this set of interfaces. Therefore, multiple RIPng processes can run on one router, and each process manages a unique set of interfaces. In addition, the routing data of each RIPng process is independent; however, processes can import routes from each other.

On routers that support VPN, each RIPng process is associated with a specific VPN instance. Therefore, all the interfaces associated with the RIPng process need to be associated with the RIPng process-related VPN instance.

### Hot Standby

Devices of a distributed architecture support RIPng Hot Standby (HSB). In the RIPng HSB process, RIPng backs up RIPng configuration from the Active Main Board (AMB) to the Standby Main Board (SMB). Whenever the AMB fails, the SMB becomes active. After the SMB is activated, RIPng resends a request to neighbors to synchronize the route database. Therefore, RIPng is not affected.

## IPsec Authentication

### Background

As networks develop, network security has become an increasing concern. Internet Protocol Security (IPsec) authentication can be used to authenticate RIPng packets. The packets that fail to be authenticated are discarded, which prevents data transmitted based on TCP/IP from being illegally obtained, tampered with, or attacked.

### Implementation

IPsec has an open standard architecture and ensures secure packet transmission on the Internet by encrypting packets. RIPng IPsec provides a complete set of security protection mechanisms to authenticate RIPng packets, which prevents devices from being attacked by forged RIPng packets.

IPsec includes a set of protocols that are used at the network layer to ensure data security, such as Internet Key Exchange (IKE), Authentication Header (AH), and Encapsulating Security Payload (ESP). The three protocols are described as follows:

- AH: A protocol that provides data origin authentication, data integrity check, and anti-replay protection. AH does not encrypt packets to be protected.
- ESP: A protocol that provides IP packet encryption and authentication mechanisms besides the functions provided by AH. The encryption and authentication mechanisms can be used together or independently.

#### NOTE

AH and ESP can be used together or independently.

### Benefits

RIPng IPsec offers the following benefits:

- Improves carriers' reputation and competitiveness by preventing services from being tampered with or attacked by unauthorized users.
- Ensures confidentiality and integrity of user packets.

## RIPng NSR

### Background

As networks develop, the demand for data, audio, and video services is growing, which imposes increasing requirements on IP network reliability. If an AMB/SMB switchover is performed on a device during a maintenance operation or a single point of failure occurs, routes may fail to converge, which may result in traffic loss or even a network breakdown. Non-stop routing (NSR) can address this problem and ensure uninterrupted forwarding of key services.

### Related Concepts

- High availability (HA): supports data backup between the AMB and SMB.
- Non-stop forwarding (NSF): enables a node to use the GR mechanism to ensure uninterrupted transmission during an AMB/SMB switchover.

- NSR: allows a standby control plane to take over traffic from an active control plane if the active control plane fails, preventing the control planes of neighbors from detecting the fault.
- AMB and SMB: run control plane processes.

## Implementation

With RIPng NSR, RIPng real-time data is synchronized between the AMB and SMB. After an AMB/SMB switchover is performed on a device, the SMB takes over services from the AMB, and neighbors are unaware of the local fault. After the switchover, the new AMB restores RIPng immediately based on the synchronized RIPng real-time data. Therefore, neighbors are unaware of the switchover as well. RIPng NSR requires synchronization of the following data:

- All configuration data, such as information about neighbors, timer parameters, and process configurations.
- Dynamic data, such as the interface parameters and state, and information about neighbors and the link state database (LSDB).

### NOTE

For details about NSR, see "Uninterruptible Service Technology" in *Feature Description - Reliability*.

## Usage Scenario

NSR minimizes the impact of control plane faults and prevents route flapping on networks that require high reliability.

## Benefits

NSR improves network reliability and ensures uninterrupted traffic forwarding.

### 1.1.7.2 RIPng Configuration

RIPng is an extension of RIP to support IPv6.

#### 1.1.7.2.1 Overview of RIPng

RIPng protocol can implement the interworking of small and medium-sized networks.

## Definition

RIP next generation (RIPng) is an extension to RIP version 2 (RIP-2) on IPv6 networks. Most RIP concepts apply to RIPng.

RIPng is a distance-vector routing protocol, which measures the distance (metric or cost) to the destination host by the hop count. In RIPng, the hop count from a device to its directly connected network is 0, and the hop count from a device to a network that is reachable through another device is 1. When the hop count is equal to or exceeds 16, the destination network or host is defined as unreachable.

To be applied on IPv6 networks, RIPng makes the following changes to RIP:

- UDP port number: RIPng uses UDP port number 521 to send and receive routing information.
- Multicast address: RIPng uses FF02::9 as the link-local multicast address of a RIPng device.
- Prefix length: RIPng uses a 128-bit (the mask length) prefix in the destination address.
- Next hop address: RIPng uses a 128-bit IPv6 address.
- Source address: RIPng uses link-local address FE80::/10 as the source address to send RIPng Update packets.

## Purpose

RIPng is an extension to RIP for support of IPv6.

### 1.1.7.2.2 Configuration Precautions for RIPng

## Feature Requirements

None

### 1.1.7.2.3 Configuring Basic RIPng Functions

To use RIPng features, configure basic RIPng functions, including creating RIPng processes and enabling RIPng on interfaces.

## Usage Scenario

While RIPng is simple and easy to use, it offers less powerful functions than OSPFv3 and IS-IS. As such, RIPng is mainly used on small-scale networks.

Configuring basic RIPng functions is a prerequisite for building RIPng networks.

## Pre-configuration Tasks

Before configuring basic RIPng functions, complete the following tasks:

- Configure a link layer protocol.
- Configure network-layer addresses for interfaces to ensure that neighboring devices are reachable at the network layer.
- Enable IPv6 in the system view.

## Creating a RIPng process

The creation of a RIPng processes is a precondition of all RIP configurations.

## Usage Scenario

Before running RIPng on a router, you need to create a RIPng process on the router.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ripng [ process-id ]**

The RIPng process is created, and the RIPng view is displayed.

RIPng supports multi-instance. To bind a RIPng process to a VPN instance, you can run the **ripng [ process-id ] vpn-instance vpn-instance-name** command.

If you run RIPng-related commands in the interface view before enabling RIPng, the configurations take effect only after RIPng is enabled.

### Step 3 (Optional) Run **description description**

A description is configured for the RIPng process.

### Step 4 Run **commit**

The configuration is submitted.

----End

## Enabling RIPng on an Interface

After an interface is associated with a RIPng process, routing information on this interface can be exchanged through RIPng.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

The interface is on the network side of the router. Specifically, the router is connected to other devices through this interface. To enable the router to learn the routes to the network segment where this interface resides, ensure that the link status of the interface is Up.

### Step 3 Run **ripng process-id enable**

RIPng is enabled on the specified interface.

- In the interface view, this command cannot be executed if IPv6 has not been enabled on the interface.
- If the router is connected to other devices through multiple interfaces, repeatedly perform Step 2 and Step 3.

### Step 4 Run **commit**

The configuration is submitted.

----End

### (Optional) Configuring the RIPng Priority

When multiple routing protocols are running on the same device, you can adjust the priority of RIPng for route selection.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run ripng [ process-id ]

The RIPng process is created and the RIPng view is displayed.

### Step 3 Run preference { preference | { route-policy route-policy-name | route-filter route-filter-name } } \*

The RIPng priority is set.

The **preference** command can be used with the routing policy to set the priority for the routes that meet the matching conditions.

After RIPng routes are delivered to the Routing Management (RM), if the RIPng priority changes, the RM updates the routing table.

### Step 4 Run commit

The configuration is submitted.

----End

### (Optional) Enabling Check on Zero Fields of RIPng Packets

Certain fields in RIPng packets must be 0, and these fields are called zero fields.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run ripng [ process-id ]

The RIPng process is created, and the RIPng view is displayed.

### Step 3 Run checkzero

The check on zero fields of RIPng packets is configured.

### Step 4 Run commit

The configuration is submitted.

----End

## Verifying the Basic RIPng Configuration

After configuring basic RIPng functions, verify the current operating status and routing information of RIPng.

### Prerequisites

Basic RIPng functions have been configured.

### Procedure

- Run the **display ripng [ process-id | vpn-instance vpn-instance-name ]** command to check the operating status and configuration of RIPng.
- Run the **display ripng process-id route [ destination-address destination-address [ mask-length ] ] [ interface interface-type interface-number [ neighbor-address neighbor-address ] ]** command to check RIPng routes.

----End

### 1.1.7.2.4 Controlling the Sending and Receiving of RIPng Packets

By controlling the sending and receiving of RIPng packets, you can optimize the RIPng performance.

### Applicable Environment

To meet the requirements of complex networking, accurately control the sending and receiving of RIPng packets.

### Pre-configuration Tasks

Before configuring a router to control the sending and receiving of RIPng packets, complete the following tasks:

- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.7.2.3 Configuring Basic RIPng Functions](#)

### Configuration Procedure

Perform one or more of the following configuration tasks (excluding "Checking the Configuration") as required.

### Disabling Receiving of RIPng Packets on an Interface

Disabling interfaces from receiving RIPng packets is a method of preventing routing loops.

### Context

When a device running RIPng is connected to a network running other routing protocols, you can run the **undo ripng input** command on the interface that connects the device to the network to prevent the interface from receiving useless packets from the network.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 3 Run **undo ripng input**

The interface is disabled from receiving RIPng packets.

### Step 4 Run **commit**

The configuration is submitted.

----End

## Disabling Sending of RIPng Packets on an Interface

Disabling an interface from sending RIPng packets is a method of preventing routing loops.

## Context

When a device running RIPng is connected to a network running other routing protocols, you can run the **undo ripng output** command on the interface that connects the device to the network to prevent the interface from sending useless packets to the network.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 3 Run **undo ripng output**

The interface is disabled from sending RIPng packets.

### Step 4 Run **commit**

The configuration is submitted.

----End

## Setting the Interval for Sending Update Packets and the Maximum Number of Packets Sent Each Time

By setting the interval for sending packets and the maximum number of packets to be sent each time, you can optimize the RIPng performance.

## Context

Perform the following steps on the RIPng router:

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 3 Run **ripng pkt-transmit { interval interval | number packet-count } \***

The interval for sending RIPng Update packets and the maximum number of packets sent each time are set on the specified interface.

### Step 4 Run **commit**

The configuration is submitted.

----End

## Verifying the Configuration of Controlling the Sending and Receiving of RIPng Packets

After controlling the sending and receiving of RIPng packets, verify the routing information in the RIPng database.

## Prerequisites

Configurations have been performed to control the sending and receiving of RIPng packets.

## Procedure

- Run the **display ripng process-id database [ verbose ] [ destination-address destination-address [ mask-length ] ] [ interface interface-type interface-number [ neighbor-address neighbor-address ] ]** command to check the routing information in the RIPng database.

----End

### 1.1.7.2.5 Preventing Routing Loops

RIPng is a distance vector routing protocol. Because RIPng devices advertise their routing tables to their neighbors, routing loops may occur.

## Usage Scenario

RIPng prevents routing loops by using the following mechanisms:

- Counting to infinity: RIPng defines the cost of 16 as infinity. If the cost of a route reaches 16 due to a routing loop, this route is considered unreachable.

- Split horizon: Split horizon prevents a RIPng-enabled interface from sending back the routes it learns, which reduces bandwidth consumption and prevents routing loops.
- Poison reverse: Poison reverse allows a RIPng-enabled interface to set the cost of the route that it learns from a neighbor to 16 (indicating that the route is unreachable) and then send the route back. After receiving this route, the neighbor deletes the useless route from its routing table, which prevents loops.
- Suppression timers: Suppress timers can prevent routing loops and reduce the possibility that receiving incorrect routes results in incorrect routing information.

 NOTE

If both split horizon and poison reverse are configured, only poison reverse takes effect.

## Pre-configuration Tasks

Before configuring RIPng to prevent routing loops on the network, complete the following tasks:

- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.7.2.3 Configuring Basic RIPng Functions](#)

## Configuration Procedure

Perform one or more of the following configurations as required.

### Configuring Split Horizon

You can configure split horizon to prevent routing loops.

### Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **interface interface-type interface-number**

The interface view is displayed.

**Step 3** Run **ripng split-horizon**

Split horizon is enabled.

If both split horizon and poison reverse are configured, only poison reverse takes effect.

**Step 4** Run **commit**

The configuration is submitted.

**----End**

## Configuring Poison Reverse

You can configure poison reverse to prevent routing loops.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

If both split horizon and poison reverse are configured, only poison reverse takes effect.

#### Step 3 Run **ripng poison-reverse**

Poison reverse is enabled.

#### Step 4 Run **commit**

The configuration is submitted.

----End

## Configuring Suppression Timers

Suppression timers can prevent routing loops and reduce the possibility that receiving incorrect routes results in incorrect routing information.

### Context

When hop count of a route increases, a device starts suppression timers and accepts the Update packet of this route and updates the routing table until the suppression timers expire.

Suppression timers delays the addition of incorrect routes to the routing Table and slows down route convergence on the entire network as well. Therefore, exercise caution when configuring the suppression timers.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **ripng process-id**

The RIPng process is created, and the RIPng view is displayed.

#### Step 3 Run **timers ripng update age suppress garbage-collect**

Suppression timers are set.

#### Step 4 Run **commit**

The configuration is submitted.

----End

## Follow-up Procedure

RIPng has four timers: *update*, *age*, *suppress*, and *garbage-collect*. The value of *update* is less than that of *age*, and the value of *suppress* is less than that of *garbage-collect*. Setting improper values for the timers affects RIP convergence speed and even causes route flapping on the network. For example, if the value of *update* is greater than that of *age*, a device cannot inform its neighbors of the change of RIP routes immediately.

For the configurations of *update*, *age*, *suppress*, and *garbage-collect*, see [1.1.7.2.8 Configuring RIPng Timers](#).

## Verifying the Configuration of Routing Loop Prevention

After configuring routing loop prevention, verify the running status of RIPng, information about interfaces, and RIPng routing information.

### Prerequisites

Routing loop prevention has been configured.

### Procedure

- Run the **display ripng [ process-id | vpn-instance vpn-instance-name ]** command to check the current operating status and configuration of RIPng.
- Run the **display ripng process-id route [ destination-address destination-address [ mask-length ] ] [ interface interface-type interface-number [ neighbor-address neighbor-address ] ]** command to check RIPng routes.
- Run the **display ripng process-id interface** command to check information about RIPng interfaces.

----End

### 1.1.7.2.6 Adjusting RIPng Route Selection

You can adjust RIPng route selection on a complicated network.

### Usage Scenario

To flexibly apply RIPng on a network and meet various requirements of users, you can change RIPng route selection by setting different parameters.

### Pre-configuration Tasks

Before adjusting RIPng route selection, complete the following tasks:

- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.7.2.3 Configuring Basic RIPng Functions](#)

## Configuration Procedure

Perform one or more of the following configurations as required.

### Configuring the Additional Metric on an Interface

The additional metric is the metric (hop count) to be added to the original metric of a RIPng route. You can set additional metrics for received RIPng routes and those to be sent.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 3 Run **ripng metricin value**

The metric to be added to received routes is set.

### Step 4 Set the metric to be added to routes to be sent.

Run any of the following commands as required:

- Configure a basic ACL:

a. Run **ripng metricout { value | { acl6-number| acl6-name acl6-name } value1 } \***

b. Run **quit**

Return to the system view.

c. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**

The ACL view is displayed.

d. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ] \*** A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.

- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.
- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:
  - Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.
  - Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.

- Based on an IP prefix list:

Run **ripng metricout { value | ipv6-prefix ipv6-prefix-name value1 }** \*

#### Step 5 Run commit

The configuration is submitted.

----End

### Follow-up Procedure

Run the **ripng metricin** command to set an additional metric for received RIPng routes. This command affects the metric of each received route in the routing table.

Run the **ripng metricout** command to set an additional metric for advertised RIPng routes. However, the metric of the route in the routing table remains unchanged.

If the metric plus the additional metric exceeds 16, 16 is used as the metric.

### Setting the Maximum Number of Equal-Cost Routes

You can set the maximum number of equal-cost RIPng routes to adjust the number of routes that load-balance traffic.

### Procedure

#### Step 1 Run interface

The system view is displayed.

#### Step 2 Run **ripng [ process-id ]**

The RIPng process is created, and the RIPng view is displayed.

#### Step 3 Run **maximum load-balancing number**

The maximum number of equal-cost routes is set.

#### Step 4 Run **commit**

The configuration is submitted.

----End

### Verifying the Configuration of RIPng Route Selection

After adjusting RIPng route selection, verify the running status of RIPng, information about interfaces, and RIPng routing information.

#### Prerequisites

RIPng route selection has been adjusted.

#### Procedure

- Run the **display ripng [ process-id | vpn-instance vpn-instance-name ]** command to check the current operating status and configuration of RIPng.
- Run the **display ripng process-id route [ destination-address destination-address [ mask-length ] ] [ interface interface-type interface-number [ neighbor-address neighbor-address ] ]** command to check RIPng routes.
- Run the **display ripng process-id interface** command to check information about RIPng interfaces.

----End

#### 1.1.7.2.7 Controlling RIPng Routing Information

In most cases, multiple protocols run on the same network. Therefore, you need to control routing information of every protocol to meet different networking requirements.

#### Applicable Environment

To meet the requirements of complex networking, accurately control the sending and receiving of RIPng routing information.

#### Pre-configuration Tasks

Before configuring a router to control RIPng routing information, complete the following tasks:

- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.7.2.3 Configuring Basic RIPng Functions](#)

#### Configuration Procedure

Perform one or more of the following configurations as required.

## Configuring RIPng to Import External Routes

RIPng can import routing information from other RIPng processes or routing protocols to enrich the RIPng routing table.

### Context

On a large-scale network, multiple routing protocols may be configured for devices in different areas. In this situation, configure RIPng to import routes from other processes or routing protocols to implement inter-area communication.

If RIPng needs to advertise routing information of other RIPbg processes or other routing protocols (such as direct, static, RIPng, OSPFv3, IS-IS, or BGP), you can specify *protocol* to filter routing information. If *protocol* is not specified, routing information to be advertised can be filtered, including the imported routes and local RIPng routes (functioning as direct routes).

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **ripng [ process-id ]**

The RIPng process is created and the RIPng view is displayed.

#### Step 3 (Optional) Run **default-cost cost**

The default cost is set for the imported routes.

If no cost is specified when external routes are imported, the default cost 0 is used.

#### Step 4 Run **import-route { static | direct | bgp [ permit-ibgp ] | unr | { isis | ospfv3 | ripng } [ process-id ] } [ [ cost cost | inherit-cost ] | { route-policy route-policy-name | route-filter route-filter-name } ] \***

External routes are imported.

#### Step 5 Run **commit**

The configuration is submitted.

----End

## Configuring RIPng to Filter the Received Routes

You can configure a router to selectively receive routes.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **ripng [ process-id ]**

The RIPng view is displayed.

**Step 3** Run the following commands as required to filter the received routes based on different policies.

- To configure ACL-based filtering, run the **filter-policy { acl6-number| acl6-name acl6-name } import** command.
  - a. Run **quit**  
Return to the system view.
  - b. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**  
The ACL view is displayed.
  - c. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ]**  
\* A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.
- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.
- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:

Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.

Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.

- To configure IP prefix list-based filtering, run the **filter-policy ipv6-prefix ipv6-prefix-name import** command.
- To configure route-policy-based filtering, run the **filter-policy route-policy route-policy-name import** command.

RIPng can filter received routes based on an IP prefix list. Only the routes that meet the matching rules are added to the RIPng routing table.

**Step 4** Run **commit**

The configuration is submitted.

----End

## Configuring RIPng to Filter the Routes to be Sent

You can configure RIPng to filter the routes to be sent.

### Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **ripng [ process-id ]**

The RIPng view is displayed.

**Step 3** Run the following commands as required to filter the routes to be sent based on different policies.

- To configure ACL-based filtering, run the **filter-policy { acl6-number | acl6-name acl6-name } export [ protocol [ process-id ] ]** command.
  - a. Run **quit**  
Return to the system view.
  - b. Run **acl ipv6 { name basic-acl6-name basic | [ number ] basic-acl6-number } [ match-order { config | auto } ]**  
The ACL view is displayed.
  - c. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment | source { source-ipv6-address { prefix-length | source-wildcard } | source-ipv6-address/prefix-length | any } | time-range time-name | [ vpn-instance vpn-instance-name | vpn-instance-any ] ]**<sup>\*</sup> A rule is configured for the ACL.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.
- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.

- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:

Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.

Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.

- To configure IP prefix list-based filtering, run the **filter-policy ipv6-prefix ipv6-prefix-name export [ protocol [ process-id ] ]** command.
- To configure a route-policy-based filtering, run the **filter-policy route-policy route-policy-name export [ protocol [ process-id ] ]** command.

RIPng can filter the routes to be sent based on an ACL6, route-policy, or an IPv6 prefix list. Only the routes that meet the match conditions are advertised to neighbors. If no protocol is specified in the command, all the routing information to be advertised will be filtered, including the imported routes and local RIPng routes (similar to direct routes).

#### Step 4 Run **commit**

The configuration is submitted.

----End

## Configuring RIPng to Advertise the Default Routes

There are two methods of advertising RIPng default routes. You can configure a router to advertise RIPng default routes as required. Alternatively, you can specify the cost of the default routes to be advertised.

## Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

#### Step 3 Run **ripng default-route { only | originate } [ cost cost | tag tag ] \***

RIPng is configured to advertise default routes.

Specify either of the following parameters as required:

- **only**: advertises only IPv6 default routes (::/0) and suppress the advertisement of other routes.

- **originate**: advertises IPv6 default routes (::/0) without affecting the advertisement of other routes.

#### Step 4 Run **commit**

The configuration is submitted.

----End

### Follow-up Procedure

RIPng default routes are advertised in Update packets through the specified interface, regardless of whether these routes exist in the IPv6 routing table.

### Configuring RIPng Route Summarization

Configuring RIPng route summarization reduces the routing table size and prevents route flapping.

### Context

The RIPng routing table of a device on a medium or large RIPng network contains a large number of routes. Storing the routes consumes a large number of memory resources, and transmitting and processing these routes consume lots of network resources. To address this issue, configure RIPng route summarization.

With RIPng route summarization, a device summarizes routes destined for different subnets of a network segment into one route destined for one network segment and then advertises the summary route to other network segments. RIPng route summarization reduces the number of routes in a routing table and minimizes system resource consumption. In addition, if a specific link frequently alternates between Up and Down, the link status changes will not be advertised to devices that are located beyond the summarized route network segment, which prevents route flapping and improves network stability.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

#### Step 3 Run **ripng summary-address ipv6-address prefix-length [ avoid-feedback ]**

RIPng route summarization is configured.

After RIPng route summarization is configured on a device, the local routing table still contains all specific routes before the summarization, while the routing tables of neighbors of the local device contain only the summarized route.

The cost of the summarized route is the smallest cost of the routes that have been summarized.

#### Step 4 Run commit

The configuration is committed.

----End

### Verifying the Configuration of RIPng Routing Information Control

After controlling RIPng routing information, verify all activated routes in the RIPng database.

### Prerequisites

Configurations have been performed to control RIPng routing information.

### Procedure

- Run the **display ripng process-id database [ verbose ] [ destination-address destination-address [ mask-length ] ] [ interface interface-type interface-number [ neighbor-address neighbor-address ] ]** command to check routes in the RIPng database.

----End

#### 1.1.7.2.8 Configuring RIPng Timers

There are four RIPng timers: Update, Age, Suppress, and Garbage-collect timers. You can adjust the RIPng convergence speed by changing the values of the RIPng timers.

### Usage Scenario

The value of *update* is less than that of *age*, and the value of *suppress* is less than that of *garbage-collect*. Setting improper values for the timers affects RIP convergence speed and even causes route flapping on the network. For example, if the value of *update* is greater than that of *age*, a device cannot inform its neighbors of the change of RIP routes immediately. Configuring Suppression timers can prevent routing loops. For details, see [Configuring Suppression Timers](#).

### Pre-configuration Tasks

Before configuring RIPng timers, complete the following tasks:

- Configure IPv6 addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- [1.1.7.2.3 Configuring Basic RIPng Functions](#)

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run ripng [ process-id ]

A RIPng process is created, and the RIPng view is displayed.

**Step 3 Run timers ripng update age suppress garbage-collect**

RIPng timers are configured.

**Step 4 Run commit**

The configuration is submitted.

----End

## Checking the Configurations

Run the following commands to check the previous configuration.

- Run the **display ripng** command to view the values of RIPng timers.

### 1.1.7.2.9 Configuring IPsec Authentication for RIPng

By default, IP security (IPsec) authentication is not configured. Configuring authentication is recommended to ensure system security.

## Applicable Environment

As networks develop rapidly, network security has become a major concern. If IPsec authentication is configured on a RIPng network, the sent and received RIPng packets will be authenticated, and those cannot pass authentication will be discarded. This can improve the security of the RIPng network.

There are two methods of configuring IPsec authentication for RIPng:

- One method is to configure IPsec authentication in RIPng processes. If IPsec authentication is enabled in a RIPng process, this configuration takes effect on all interfaces in this RIPng process. This method is recommended if IPsec authentication needs to be applied to all interfaces in a RIPng process.
- The other method is to configure IPsec authentication on RIPng interfaces. This method is recommended if IPsec authentication needs to be applied only to some interfaces in a RIPng process.

## Pre-configuration Tasks

Before configuring IPsec authentication for RIPng, complete the following tasks:

- Configuring basic IPsec functions
- [Configuring Basic RIPng Functions](#)

## Configuring IPsec Authentication for a RIPng Process

Configuring IP security (IPsec) authentication in the RIPng view is one of the methods used to configure IPsec authentication for RIPng.

## Context

After IPsec authentication is configured in the RIPng view, all interfaces in this RIPng process perform IPsec authentication on RIPng packets received and to be sent.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **ripng [ process-id ]**

The RIPng view is displayed.

### Step 3 Run **ipsec sa sa-name**

IPsec authentication is enabled, and the name of a security association (SA) is specified.

### Step 4 Run **commit**

The configuration is committed.

----End

## Configuring IPsec Authentication on a RIPng Interface

Configuring IP security (IPsec) authentication in the interface view is the other method used to configure IPsec authentication for RIPng.

## Context

An SA configured on an RIPng interface is used to authenticate the packets sent and received by the interface.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 3 Run **ripng ipsec sa sa-name**

IPsec authentication is enabled on the interface, and the name of an SA is specified.

The **ripng ipsec sa** command takes precedence over the **ipsec sa** command. If both commands are run in respective views and different SA names are specified, only the configuration of the **ripng ipsec sa** command takes effect.

### Step 4 Run **commit**

The configuration is committed.

----End

## Verifying the Configuration of IPsec Authentication for RIPng

After IP security (IPsec) authentication for RIPng is configured, you can check the security association (SA) used in IPsec authentication and statistics on the RIPng packets that failed authentication.

### Prerequisites

After IPsec authentication is enabled in a RIPng process or on a RIPng interface, the configuration takes effect immediately. There is no need to restart the RIPng process.

### Procedure

- Run the **display ripng process-id interface [ interface-type interface-number ] [ verbose ]** command to check the SA used in IPsec authentication.
- Run the **display ripng process-id statistics interface { all | interface-type interface-number [ verbose | neighbor neighbor-ipv6-address ] }** command to check the number of RIPng packets that failed authentication.

----End

### 1.1.7.2.10 Maintaining RIPng

RIPng maintenance is implemented through debugging. Debugging, however, affects the system performance.

### Clearing RIPng

To clear RIPng information, run the reset commands in the user view.

### Context

#### NOTICE

RIPng information cannot be restored after you clear it. Therefore, exercise caution when running the reset command.

### Procedure

- Run the **reset ripng process-id statistics interface { all | interface-type interface-number [ neighbor neighbor-ipv6-address ] }** command to clear the statistics of the counter that is maintained by a particular RIPng process. This command helps to re-collect statistics during debugging.

----End

### Debugging RIPng

If the debugging of a module is enabled in the user view, the device can generate debugging information. Debugging information shows the contents of the packets received or sent by the debugged module.

## Context

### NOTICE

Debugging affects system performance. Therefore, after debugging is complete, run the **undo debugging all** command to disable debugging immediately.

If a RIPng fault occurs, you can run the **debugging** command in the user view to enable RIPng debugging. The debugging information helps you locate and analyze the fault.

## Procedure

- Run the **debugging ripng process-id [ error | event | job | backup | interface interface-type interface-number ] | packet [ interface-type interface-number [ neighbor neighbor-address ] ] | route acl-number ] | route-processing [ acl-number ] ]** command to enable debugging for the RIPng process.
- Run the **debugging ripng miscellaneous** command to debug RIPng component-level information.

----End

### 1.1.7.2.11 RIPng Configuration Examples

This section provides RIPng configuration examples.

### Example for Configuring Basic RIPng Functions

This section describes how to configure basic RIPng functions.

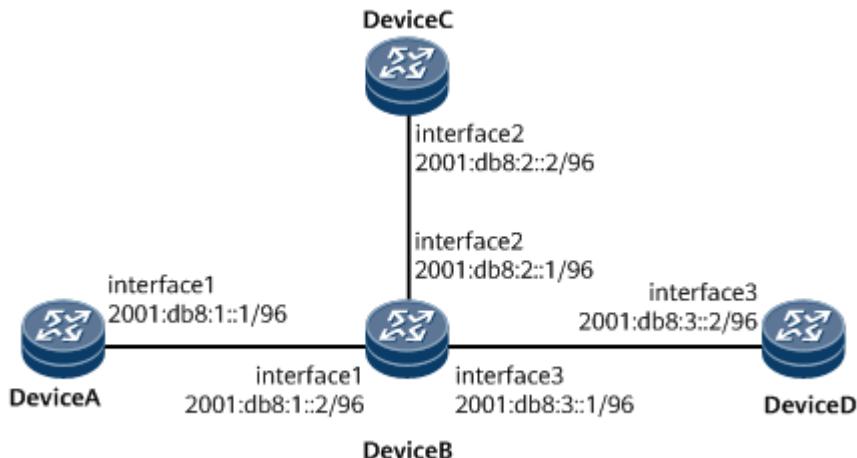

### Networking Requirements

On the network shown in [Figure 1-222](#), it is required that RIPng be enabled on all interfaces of DeviceA, DeviceB, DeviceC, and DeviceD and that these interfaces communicate with each other through RIPng.

**Figure 1-222** Network diagram of basic RIPng function configuration

### NOTE

In this example, interface1, interface2, and interface3 represent GE1/0/0, GE2/0/0, and GE3/0/0, respectively.

## Precautions

During the configuration, note the following:

- RIPng takes effect on an interface only after IPv6 is enabled.
- If a RIPng process is bound to a VPN instance, the interfaces running the RIPng process are also bound to the VPN instance.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Assign an IPv6 address to each interface to ensure network connectivity.
2. Enable RIPng and configure basic RIPng functions on each router.
3. Configure IPsec authentication for a RIPng process.

## Data Preparation

To complete the configuration, you need the following data:

- IPv6 address of the interface.

## Procedure

**Step 1** Assign an IPv6 address to each interface. For configuration details, see configuration files in this section.

**Step 2** Configure basic RIPng functions.

# Configure DeviceA.

```
[*DeviceA] ripng 1
[*DeviceA-ripng-1] quit
[*DeviceA] interface gigabitethernet1/0/0
[*DeviceA-GigabitEthernet1/0/0] ipv6 enable
[*DeviceA-GigabitEthernet1/0/0] ripng 1 enable
[*DeviceA-ripng-1] quit
[*DeviceA] commit
```

# Configure DeviceB.

```
[*DeviceB] ripng 1
[*DeviceB-ripng-1] quit
[*DeviceB] interface gigabitethernet1/0/0
[*DeviceB-GigabitEthernet1/0/0] ipv6 enable
[*DeviceB-GigabitEthernet1/0/0] ripng 1 enable
[*DeviceB-GigabitEthernet1/0/0] quit
[*DeviceB] interface gigabitethernet2/0/0
[*DeviceB-GigabitEthernet2/0/0] ipv6 enable
[*DeviceB-GigabitEthernet2/0/0] ripng 1 enable
[*DeviceB-GigabitEthernet2/0/0] quit
[*DeviceB] interface gigabitethernet3/0/0
[*DeviceB-GigabitEthernet3/0/0] ipv6 enable
[*DeviceB-GigabitEthernet3/0/0] ripng 1 enable
[*DeviceB-GigabitEthernet3/0/0] quit
[*DeviceB] commit
```

# Configure DeviceC.

```
[*DeviceC] ripng 1
[*DeviceC-ripng-1] quit
[*DeviceC] interface gigabitethernet2/0/0
[*DeviceC-GigabitEthernet2/0/0] ipv6 enable
[*DeviceC-GigabitEthernet2/0/0] ripng 1 enable
[*DeviceC-GigabitEthernet2/0/0] quit
[*DeviceC] commit
```

# Configure DeviceD.

```
[*DeviceD] ripng 1
[*DeviceD-ripng-1] quit
[*DeviceD] interface gigabitethernet3/0/0
[*DeviceD-GigabitEthernet3/0/0] ipv6 enable
[*DeviceD-GigabitEthernet3/0/0] ripng 1 enable
[*DeviceD-GigabitEthernet3/0/0] quit
[*DeviceD] commit
```

### Step 3 Configure IPsec authentication for a RIPng process.

# Create an IPSec proposal on DeviceA.

```
[~DeviceA] ipsec proposal proposal1
[*DeviceA-ipsec-proposal-proposal1] encapsulation-mode transport
[*DeviceA-ipsec-proposal-proposal1] transform esp
[*DeviceA-ipsec-proposal-proposal1] esp authentication-algorithm sha2-256
[*DeviceA-ipsec-proposal-proposal1] commit
[~DeviceA-ipsec-proposal-proposal1] quit
```

# Configure an IPsec SA and apply the IPsec proposal to the SA on DeviceA.

```
[~DeviceA] ipsec sa sa1
[*DeviceA-ipsec-sa-sa1] proposal proposal1
[*DeviceA-ipsec-sa-sa1] commit
```

# Configure an SPI and a key in the string format on DeviceA.

```
[~DeviceA] ipsec sa sa1
[*DeviceA-ipsec-sa-sa1] sa spi inbound esp 12345
[*DeviceA-ipsec-sa-sa1] sa spi outbound esp 12345
[*DeviceA-ipsec-sa-sa1] sa string-key inbound esp abcdef
[*DeviceA-ipsec-sa-sa1] sa string-key outbound esp abcdef
[*DeviceA-ipsec-sa-sa1] commit
[~DeviceA-ipsec-sa-sa1] quit
```

# Configure an SA in the RIPng process on DeviceA.

```
[~DeviceA] ripng 1
[*DeviceA-ripng-1] ipsec sa sa1
[*DeviceA-ripng-1] commit
```

The configurations of other devices are similar to the configuration of DeviceA. For configuration details, see configuration files.

**Step 4** Verify the configuration.

# Check the neighbors of DeviceA.

```
[~DeviceA] display ripng 1 neighbor
Neighbor : FE80::A0A:201:1 GigabitEthernet1/0/0
Protocol : RIPNG
```

The command output shows that DeviceA has established neighbor relationships with other devices on the network.

# Check the routing information of DeviceB.

```
[~DeviceB] display ripng 1 route
Route Flags: A - Aging, S - Suppressed, G - Garbage-collect

Peer FE80::F54C:0:9FDB:1 on GigabitEthernet1/0/0
Dest 2001:DB8:1::1/96,
 via FE80::F54C:0:9FDB:1, cost 1, tag 0, A, 3 Sec
Peer FE80::D472:0:3C23:1 on GigabitEthernet2/0/0
Dest 2001:DB8:2::2/96,
 via FE80::D472:0:3C23:1, cost 1, tag 0, A, 4 Sec
Peer FE80::D472:0:3C23:1 on GigabitEthernet3/0/0
Dest 2001:DB8:3::2/96,
 via FE80::D472:0:3C23:1, cost 1, tag 0, A, 4 Sec
```

The command output shows that DeviceB has learned routing information on the network.

----End

## Configuration Files

## Example for Configuring Split Horizon

This section describes how to configure split horizon to prevent routing loops.

### Networking Requirements

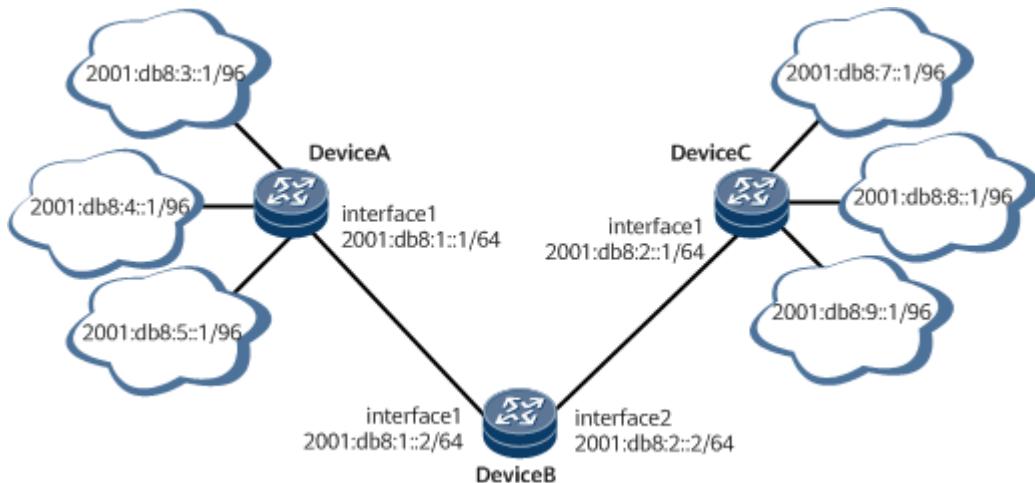

On the network shown in [Figure 1-223](#), IP addresses have been configured for interfaces on all routers, RIPng has been configured on each router, and RIPng services are running properly. Split horizon needs to be re-configured on DeviceA and DeviceC.

**Figure 1-223** Network diagram of split horizon

NOTE

Interface 1 and Interface 2 in this example represent GE 1/0/0 and GE 2/0/0, respectively.

## Precautions

During the configuration, note the following:

When the split horizon and poison reverse are configured together, only poison reverse takes effect.

To improve security, you are advised to deploy IPsec authentication for RIPng. For details, see Configuring IPsec Authentication for RIPng. The following uses IPsec authentication in a RIPng process as an example. For details, see Example for Configuring Basic RIPng Functions.

## Configuration Roadmap

The configuration roadmap is as follows:

1. Enable split horizon.

## Data Preparation

To complete the configuration, you need the following data:

- RIPng network segments of DeviceA: 2001:db8:3::1/96, 2001:db8:4::1/96, and 2001:db8:5::1/96
- RIPng network segments of DeviceB: 2001:db8:1::2/64 and 2001:db8:2::2/64
- RIPng network segments of DeviceC: 2001:db8:7::1/96, 2001:db8:8::1/96, and 2001:db8:9::1/96
- IPv6 address of each interface

## Procedure

### Step 1 Configure split horizon.

Configure split horizon on the RIPng interfaces of all routers. The configuration of DeviceC is the same as the configuration of DeviceA and DeviceB, and is not mentioned here.

```
Configure DeviceA.
```

```
[~DeviceA] interface gigabitethernet1/0/0
[~DeviceA-GigabitEthernet1/0/0] ripng split-horizon
[*DeviceA-GigabitEthernet1/0/0] quit
[~DeviceA] interface gigabitethernet1/0/1
[~DeviceA-GigabitEthernet1/0/1] ripng split-horizon
[*DeviceA-GigabitEthernet1/0/1] quit
[~DeviceA] interface gigabitethernet1/0/2
[~DeviceA-GigabitEthernet1/0/2] ripng split-horizon
[*DeviceA-GigabitEthernet1/0/2] quit
[~DeviceA] interface gigabitethernet1/0/3
[~DeviceA-GigabitEthernet1/0/3] ripng split-horizon
[*DeviceA-GigabitEthernet1/0/3] quit
[*DeviceA] commit
```

**Step 2** Verify the configuration.

# Run the **display ripng 1 interface verbose** command on DeviceA and DeviceC to check the split horizon configuration. Use the command output on DeviceA as an example. If the displayed Split-Horizon field is Enabled, split horizon has been enabled.

```
[~DeviceA] display ripng 1 interface verbose
GigabitEthernet1/0/0
 FE80::A0A:200:1
 State : UP, Protocol : RIPNG, MTU : 1440
 Metricin : 0 , Metricout : 1
 Default Route : Disabled
 Poison Reverse : Disabled
 Split Horizon : Enabled
GigabitEthernet1/0/1(10.1.1.1)
 FE80::A0A:200:1
 State : UP, Protocol : RIPNG, MTU : 1440
 Metricin : 0 , Metricout : 1
 Default Route : Disabled
 Poison Reverse : Disabled
 Split Horizon : Enabled
GigabitEthernet1/0/2
 FE80::A0A:200:1
 State : UP, Protocol : RIPNG, MTU : 1440
 Metricin : 0 , Metricout : 1

## 1.1.8 IS-IS Configuration

### 1.1.8.1 IS-IS Description

#### 1.1.8.1.1 Overview of IS-IS

##### Definition

Intermediate System to Intermediate System (IS-IS) is a dynamic routing protocol initially designed by the International Organization for Standardization (ISO) for the Connectionless Network Protocol (CLNP).

To support IP routing, the IETF extends and modifies IS-IS in relevant standards, which enables IS-IS to be applied to both TCP/IP and Open System Interconnection (OSI) environments. The new type of IS-IS is called integrated IS-IS or dual IS-IS.

In this document, IS-IS refers to integrated IS-IS, unless otherwise stated.

Unless otherwise specified, IS-IS features that support both IPv4 and IPv6 are implemented in the same way.

##### Purpose

IS-IS is an Interior Gateway Protocol (IGP) and is used within an autonomous system (AS). IS-IS is a link state protocol, and it uses the shortest path first (SPF) algorithm to calculate routes.

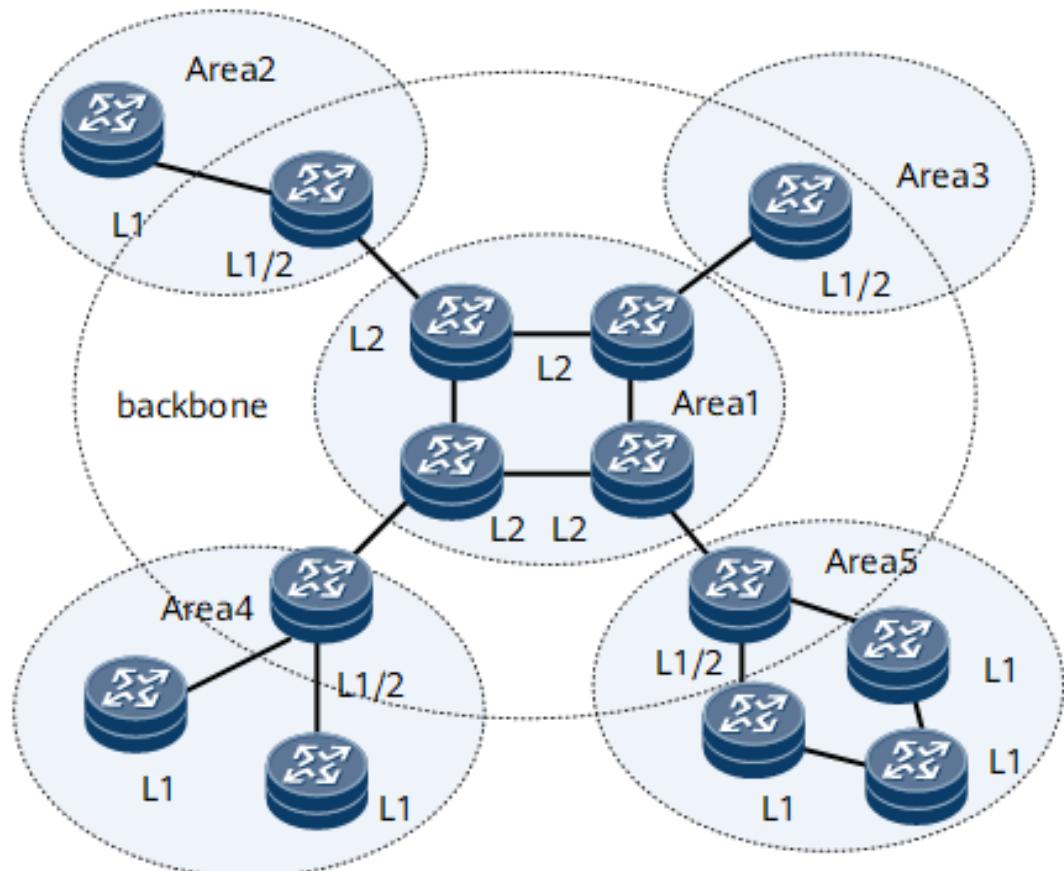

#### 1.1.8.1.2 Understanding IS-IS

##### Basic Concepts of IS-IS

##### IS-IS Areas

To support large-scale routing networks, IS-IS adopts a two-level structure in a routing domain. A large domain can be divided into areas. [Figure 1-224](#) shows an IS-IS network. The entire backbone area covers all Level-2 routers in area 1 and Level-1-2 routers in other areas. Three types of routers on the IS-IS network are described as follows:

Figure 1-224 IS-IS topology

- Level-1 router

A Level-1 router manages intra-area routing. It establishes Level-1 neighbor relationships only with other Level-1 devices and Level-1-2 routers in the same area, and maintains only a Level-1 link state database (LSDB) which contains routing information specific to the local area. For packets destined for other areas, each Level-1 router forwards them to the nearest Level-1-2 router.

- Level-2 router

A Level-2 router manages inter-area routing. It can establish Level-2 neighbor relationships with other Level-2 routers and with Level-1-2 routing devices in other areas and maintains a Level-2 LSDB, which contains inter-area routing information.

All Level-2 routers form the backbone network of the routing domain and are responsible for inter-area communication. The Level-2 routers in the routing domain must be contiguous to ensure backbone network continuity. Only Level-2 routers can directly exchange data packets or routing information with the routers beyond the area.

- Level-1-2 router

A router that belongs to both Level-1 and Level-2 areas is called a Level-1-2 router. It can establish Level-1 neighbor relationships with Level-1 routers in the same area, Level-2 neighbor relationships with Level-2 routers in other

areas, and Level-1 and Level-2 neighbor relationships with Level-1-2 routers. Level-1 routers can be connected to other areas only through Level-1-2 routers.

A Level-1-2 router maintains two LSDBs: a Level-1 LSDB and a Level-2 LSDB. The Level-1 LSDB is used for intra-area routing, whereas the Level-2 LSDB is used for inter-area routing.

#### NOTE

Level-1 routers in different areas cannot establish neighbor relationships. Level-1-2 routers can establish neighbor relationships with each other, regardless of the areas to which they belong.

Generally, Level-1 routers are deployed within an area, Level-2 routers are deployed between areas, and Level-1-2 routers are deployed between Level-1 and Level-2 routers.

#### Interface level

A Level-1-2 router may need to establish only a Level-1 adjacency with a peer and establish only a Level-2 adjacency with another peer. In this case, you can set the level of an interface to control the setting of adjacencies on the interface. Specifically, only Level-1 adjacencies can be established on a Level-1 interface, and only Level-2 adjacencies can be established on a Level-2 interface.

## Address Structure of IS-IS

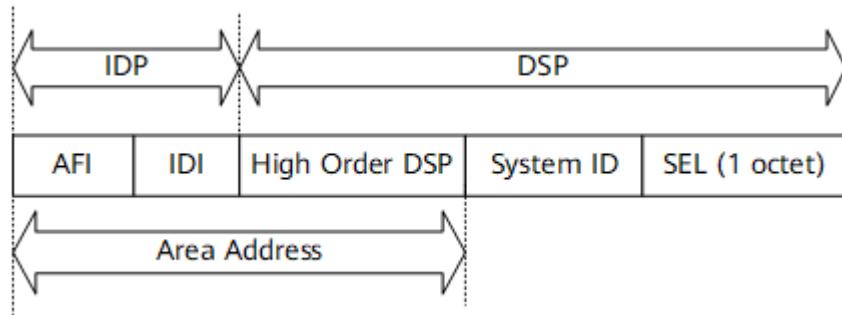

In OSI, the NSAP is used to locate resources. The ISO adopts the address structure shown in [Figure 1-225](#). An NSAP is composed of the Initial Domain Part (IDP) and the Domain Specific Part (DSP). IDP is the counterpart of network ID in an IP address, and DSP is the counterpart of the subnet number and host address in an IP address.

As defined by the ISO, the IDP consists of the Authority and Format Identifier (AFI) and Initial Domain Identifier (IDI). AFI specifies the address assignment mechanism and the address format; the IDI identifies a domain.

The DSP consists of the High Order DSP (HODSP), system ID, and NSAP Selector (SEL). The HODSP is used to divide areas; the system ID identifies a host; the SEL indicates the service type.

The lengths of the IDP and DSP are variable. The length of the NSAP varies from 8 bytes to 20 bytes.

**Figure 1-225** IS-IS address structure

- Area address

An IDP and HODSP of the DSP can identify a routing domain and the areas in a routing domain; therefore, the combination of the IDP and HODSP is referred to as an area address, equal to an area ID in OSPF. You are advised to avoid the situation where different Level-1 areas in the same routing domain have the same area address. The area addresses of routers in the same Level-1 area must be the same.

A router generally requires only one area address, and the area addresses of all nodes in the same area must be the same. In the implementation of a device, an IS-IS process can be configured with a maximum of three area addresses to support seamless combination, division, and transformation of areas.

- System ID

A system ID uniquely identifies a host or a router in an area. In the device, the length of the system ID is 48 bits (6 bytes).

A router ID corresponds to a system ID. If a router uses the IP address (192.168.1.1) of Loopback 0 as its router ID, its system ID used in IS-IS can be obtained through the following steps:

- Extend each part of the IP address 192.168.1.1 to 3 digits and add 0 or 0s to the front of the part that is shorter than 3 digits.
- Divide the extended address 192.168.001.001 into three parts, with each part consisting of 4 decimal digits.
- The reconstructed 1921.6800.1001 is the system ID.

There are many ways to specify a system ID. Whichever you choose, ensure that the system ID uniquely identifies a host or a router.

 NOTE

If the same system ID is configured for more than one device on the same network, network flapping may occur. To address this problem, IS-IS provides the automatic recovery function. With the function, if the system detects an IS-IS system ID conflict, it automatically changes the local system ID to resolve the conflict. The first two bytes of the system ID automatically changed by the system are Fs, and the last four bytes are randomly generated. For example, FFFF:1234:5678 is such a system ID. If the conflict persists after the system automatically changes three system IDs, the system no longer resolves this conflict.

- SEL

The role of an SEL (also referred to as NSAP Selector or N-SEL) is similar to that of the "protocol identifier" of IP. A transport protocol matches an SEL. The SEL is "00" in IP.

- NET

A Network Entity Title (NET) indicates the network layer information of an IS itself and consists of an area ID and a system ID. It does not contain the transport layer information (SEL = 0). A NET can be regarded as a special NSAP. The length of the NET field is the same as that of an NSAP, varying from 8 bytes to 20 bytes. For example, in NET **ab.cdef.1234.5678.9abc.00**, the area is **ab.cdef**, the system ID is **1234.5678.9abc**, and the SEL is **00**.

In general, an IS-IS process is configured with only one NET. When areas need to be redefined, for example, areas need to be combined or an area needs to be divided into sub-areas, you can configure multiple NETs.

#### NOTE

A maximum of three area addresses can be configured in an IS-IS process, and therefore, you can configure only a maximum of three NETs. When you configure multiple NETs, ensure that their system IDs are the same.

The routers in an area must have the same area address.

## IS-IS Network Types

IS-IS supports the following types of networks:

- Broadcast network
- Point-to-point (P2P) network

## Basic Protocols of IS-IS

### Related Concepts

#### DIS and Pseudo Node

A Designated Intermediate System (DIS) is an intermediate router elected in IS-IS communication. A pseudo node simulates a virtual node on a broadcast network and is not a real router. In IS-IS, a pseudo node is identified by the system ID and 1-byte circuit ID (a non-zero value) of a DIS.

The DIS is used to create and update pseudo nodes and generate the [link state protocol data units \(LSPs\)](#) of pseudo nodes. The routers advertise a single link to a pseudo node and obtain routing information about the entire network through the pseudo node. The router does not need to exchange packets with all the other routers on the network. Using the DIS and pseudo nodes simplifies network topology and reduces the length of LSPs generated by routers. When the network changes, fewer LSPs are generated. Therefore, fewer resources are consumed.

#### SPF Algorithm

The SPF algorithm, also named Dijkstra's algorithm, is used in a link-state routing protocol to calculate the shortest paths to other nodes on a network. In the SPF algorithm, a local router takes itself as the root and generates a shortest path tree (SPT) based on the network topology to calculate the shortest path to every destination node on a network. In IS-IS, the SPF algorithm runs separately in Level-1 and Level-2 databases.

## Implementation

All routers on the IS-IS network communicate through the following steps:

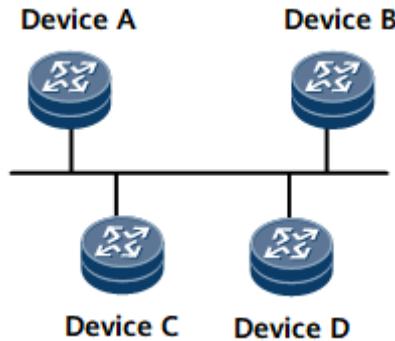

- [Establishment of IS-IS Neighbor Relationships](#)
- [LSDB Synchronization](#)
- [Route Calculation](#)

#### Establishment of IS-IS Neighbor Relationships

On different types of networks, the modes for establishing IS-IS neighbor relationships are different.

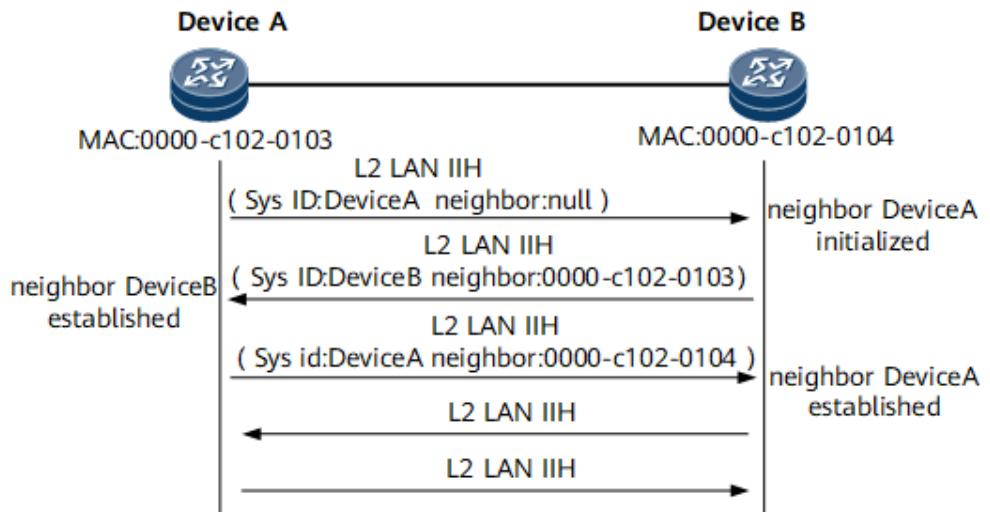

- Establishment of a neighbor relationship on a broadcast link

Figure 1-226 Networking for a broadcast link

Device A, Device B, Device C, and Device D are Level-2 routers. Device A is newly added to the broadcast network. [Figure 1-227](#) demonstrates the process of establishing the neighbor relationship between Device A and Device B, the process of establishing the neighbor relationship between Device A and Device C or Device D is similar to that between Device A and Device B.

Figure 1-227 Establishing a neighbor relationship on a broadcast link

As shown in [Figure 1-227](#), the process for establishing a neighbor relationship on a broadcast link consists of the following phases:

- Device A broadcasts a Level-2 local area network (LAN) **IS-to-IS Hello PDU (IIH)**. After Device B receives the IIH, Device B detects that the neighbor field in the IIH does not contain its media access control (MAC) address, and sets its neighbor status with Device A to **Initial**.
- Device B replies a Level-2 LAN IIH to Device A. After Device A receives the IIH, Device A detects that the neighbor field in the IIH contains its MAC address, and sets its neighbor status with Device B to **Up**.

- Device A sends a Level-2 LAN IIH to Device B. After Device B receives the IIH, Device B detects that the neighbor field in the IIH contains its MAC address, and sets its neighbor status with Device A to **Up**.

### DIS Election

On a broadcast network, any two routers exchange information. If n routers are available on the network,  $n \times (n - 1)/2$  adjacencies must be established. Each status change of a router is transmitted to other routers, which wastes bandwidth resources. IS-IS resolves this problem by introducing the DIS. All routers send information to the DIS, which then broadcasts the network link status. Using the DIS and pseudo nodes simplifies network topology and reduces the length of LSPs generated by routers. When the network changes, fewer LSPs are generated. Therefore, fewer resources are consumed.

A DIS is elected after a neighbor relationship is established. Level-1 and Level-2 DISs are elected separately. You can configure different priorities for DISs at different levels. In DIS election, a Level-1 priority and a Level-2 priority are specified for every interface on every router. A router uses every interface to send IIHs and advertises its priorities in the IIHs to neighboring routers. The higher the priority, the higher the probability of being elected as the DIS. If there are multiple routers with the same highest priority on a broadcast network, the one with the largest MAC address is elected. The DISs at different levels can be the same router or different routers.

In the DIS election procedure, IS-IS is different from Open Shortest Path First (OSPF). In IS-IS, DIS election rules are as follows:

- The router with the priority of 0 also takes part in the DIS election.
- When a new router that meets the requirements of being a DIS is added to the broadcast network, the router is selected as the new DIS, which triggers a new round of LSP flooding.
- Establishment of a neighbor relationship on a P2P link

The establishment of a neighbor relationship on a P2P link is different from that on a broadcast link. A neighbor relationship on a P2P link can be established in 2-way or 3-way mode, as shown in [Table 1-81](#). By default, the 3-way handshake mechanism is used to establish a neighbor relationship on a P2P link.

**Table 1-81** Comparison between 2-way mode and 3-way mode

| Mode       | Description                                                                         | Advantages and Disadvantages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Reliability |
|------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 2-way mode | When a router receives an IIH, it unidirectionally sets up a neighbor relationship. | <p>Disadvantages:</p> <ul style="list-style-type: none"> <li>The unstable link status causes the loss of <b>complete sequence numbers protocol data units (CSNPs)</b> that are sent once an adjacency is set up. As a result, the link state databases (LSDBs) of two neighboring routers are not synchronized during the LSP update period.</li> <li>If two or more links exist between two routers, an adjacency can still be set up when one link is Down and another is Up in the same direction. A router that fails to detect the faulty link may also forward packets over this link.</li> </ul> | Low         |

| Mode       | Description                                                             | Advantages and Disadvantages                                                                                                                 | Reliability |
|------------|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 3-way mode | A neighbor relationship is established after IIHs are sent three times. | Advantages: A neighbor relationship is established only when both ends are Up. This mechanism ensures that packets are transmitted securely. | High        |

### LSDB Synchronization

IS-IS is a link-state protocol. An IS-IS router obtains first-hand information from other routers running link-state protocols. Every router generates information about itself, directly connected networks, and links between itself and directly connected networks. The router then sends the generated information to other routers through adjacent routers. Every router saves link state information without modifying it. Finally, every router has the same network interworking information, and LSDB synchronization is complete. The process of synchronizing LSDBs is called LSP flooding. In LSP flooding, a router sends an LSP to its neighbors and the neighbors send the received LSP to their neighbors except the router that first sends the LSP. The LSP is flooded among the routers at the same level. This implementation allows each router at the same level to have the same LSP information and keep a synchronized LSDB.

All routers in the IS-IS routing domain can generate LSPs. A new LSP is generated in any of the following situations:

- Neighbor goes Up or Down.
- related interface goes Up or Down.
- Imported IP routes change.
- Inter-area IP routes change.
- A new metric value is configured for an interface.
- Periodic updates occur.

A router processes a received LSP as follows:

- Updating the LSDB on a broadcast link

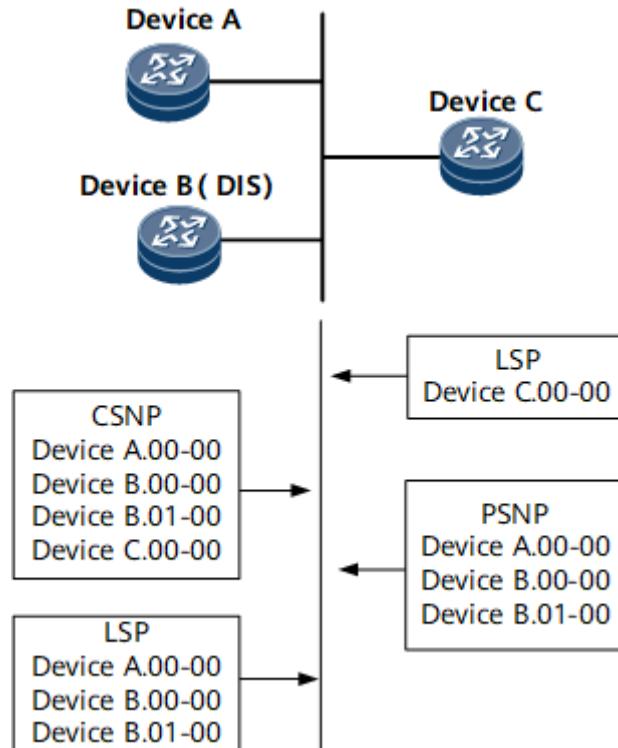

The DIS updates the LSDB to synchronize LSDBs on a broadcast network.

[Figure 1-228](#) shows the process of synchronizing LSDBs on a broadcast network.

- a. When the DIS receives an LSP, it searches the LSDB for the related records. If the DIS does not find the LSP in its LSDB, it adds the LSP to its LSDB and broadcasts the new LSDB.
- b. If the sequence number of the received LSP is greater than that of the local LSP, the DIS replaces the local LSP with the received LSP in the LSDB and broadcasts the new LSDB.

- c. If the sequence number of the received LSP is less than that of the local LSP, the DIS sends the local LSP in the LSDB to the inbound interface.
- d. If the sequence number of the received LSP is equal to that of the local LSP, the DIS compares the Remaining Lifetime of the two LSPs. If Remaining Lifetime of the received LSP is 0, the DIS replaces the LSP with the received LSP, and broadcasts the new LSDB. If the Remaining Lifetime of local LSP is 0, the DIS sends the LSP to the inbound interface.
- e. If the sequence number of the received LSP and the local LSP in the LSDB are the same and neither Remaining Lifetime is 0, the DIS compares the checksum of the two LSPs. If the received LSP has a greater checksum than that of the local LSP in the LSDB, the DIS replaces the local LSP in the LSDB with the received LSP and advertises the new LSDB. If the received LSP has a smaller checksum than that of the local LSP in the LSDB, the DIS sends the local LSP in the LSDB to the inbound interface.
- f. If the checksums of the received LSP and the local LSP are the same, the LSP is not forwarded.

**Figure 1-228** Process of updating the LSDB on a broadcast link

- Updating the LSDB on a P2P link
  - a. If the sequence number of the received LSP is greater than that of the local LSP in the LSDB, the router adds the received LSP to its LSDB. The router then sends a **PSNP packet** to acknowledge the received LSP and sends the LSP to all its neighbors except the neighbor that sends the LSP.
  - b. If the sequence number of the received LSP is less than that of the local LSP, the router directly sends its LSP to the neighbor and waits for a PSNP from the neighbor as an acknowledgement.

- c. If the sequence number of the received LSP is the same as that of the local LSP in the LSDB, the router compares the Remaining Lifetimes of the two LSPs. If Remaining Lifetime of the received LSP is 0, the router adds the LSP to its LSDB. The router then sends a PSNP to acknowledge the received LSP. If Remaining Lifetime of the local LSP is 0, the router directly sends the local LSP to the neighbor and waits for a PSNP from the neighbor.
- d. If the sequence number of the received LSP and the local LSP in the LSDB are the same, and neither Remaining Lifetime is 0, the router compares the checksum of the two LSPs. If the received LSP has a greater checksum than that of the local LSP, the router adds the received LSP to its LSDB. The router then sends a PSNP to acknowledge the received LSP. If the received LSP has a smaller checksum than that of the local LSP, the router directly sends the local LSP to the neighbor and waits for a PSNP from the neighbor. At last, the router sends the LSP to all its neighbors except the neighbor that sends the LSP.
- e. If the checksums of the received LSP and the local LSP are the same, the LSP is not forwarded.

### Route Calculation

When LSDB synchronization is complete and network convergence is implemented, IS-IS performs SPF calculation by using LSDB information to obtain the SPT. IS-IS uses the SPT to create a forwarding database (a routing table).

In IS-IS, link costs are used to calculate shortest paths. The default cost for an interface on a Huawei router is 10. The cost is configurable. The cost of a route is the sum of the cost of every outbound interface along the route. There may be multiple routes to a destination, among which the route with the smallest cost is the optimal route.

Level-1 routers can also calculate the shortest path to Level-2 routers to implement inter-area route selection. When a Level-1-2 router is connected to other areas, the router sets the value of the attachment (ATT) bit in its LSP to 1 and sends the LSP to neighboring routers. In the route calculation process, a Level-1 router selects the nearest Level-1-2 router as an intermediate router between the Level-1 and Level-2 areas.

### IS-IS Routing Information Control

IS-IS routes calculated using the SPF algorithm may bring about some problems. For example, too many routing entries slow down route lookup, or link usage is unbalanced. As a result, IS-IS routing cannot meet carriers' network planning and traffic management requirements.

To optimize IS-IS networks and facilitate traffic management, more precise route control is required. IS-IS uses the following methods to control routing information:

- [Route Leaking](#)
- [Route Summarization](#)
- [Load Balancing](#)
- [Administrative Tag](#)
- [IS-IS Mesh Group](#)

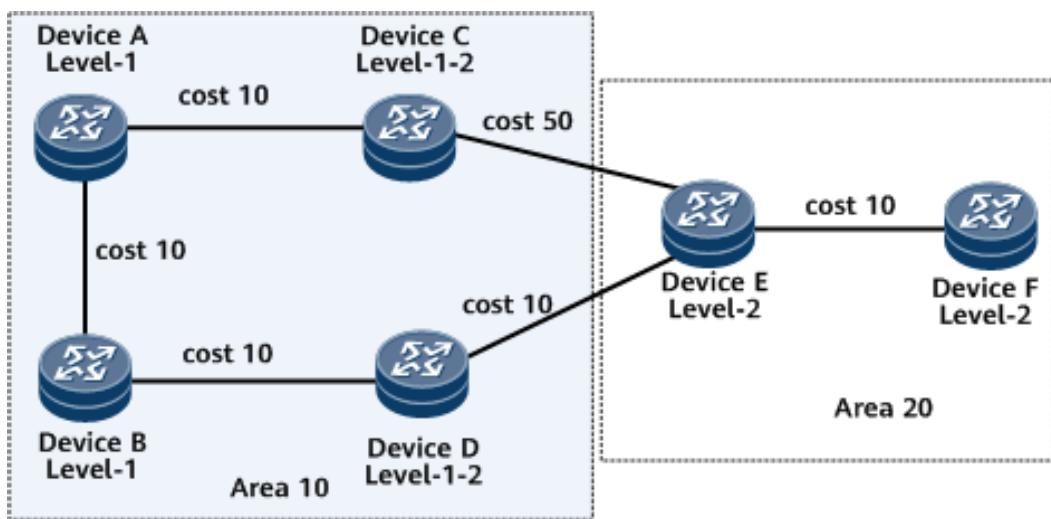

- [Link-group](#)

### Route Leaking

When Level-1 and Level-2 areas both exist on an IS-IS network, Level-2 routers do not advertise the learned routing information about a Level-1 area and the backbone area to any other Level-1 area by default. Therefore, Level-1 routers do not know the routing information beyond the local area. As a result, the Level-1 routers cannot select the optimal routes to the destination beyond the local area.

With route leaking, Level-1-2 routers can select routes using routing policies, or tags and advertise the selected routes of other Level-1 areas and the backbone area to the Level-1 area. [Figure 1-229](#) shows the typical networking for route leaking.

**Figure 1-229** Typical networking for route leaking

- Device A, Device B, Device C, and Device D belong to area 10. Device A and Device B are Level-1 routers. Device C and Device D are Level-1-2 routers.
- Device E and Device F belong to area 20 and are Level-2 routers.

If Device A sends a packet to Device F, the selected optimal route should be Device A -> Device B -> Device D -> Device E -> Device F because its cost is 40 ( $10 + 10 + 10 + 10 = 40$ ) which is less than that of Device A -> Device C -> Device E -> Device F ( $10 + 50 + 10 = 70$ ). However, if you check routes on Device A, you can find that the selected route is Device A -> Device C -> Device E -> Device F, which is not the optimal route from Device A to Device F.

This is because Device A does not know the routes beyond the local area, and therefore, the packets sent by Device A to other network segments are sent through the default route generated by the nearest Level-1-2 device.

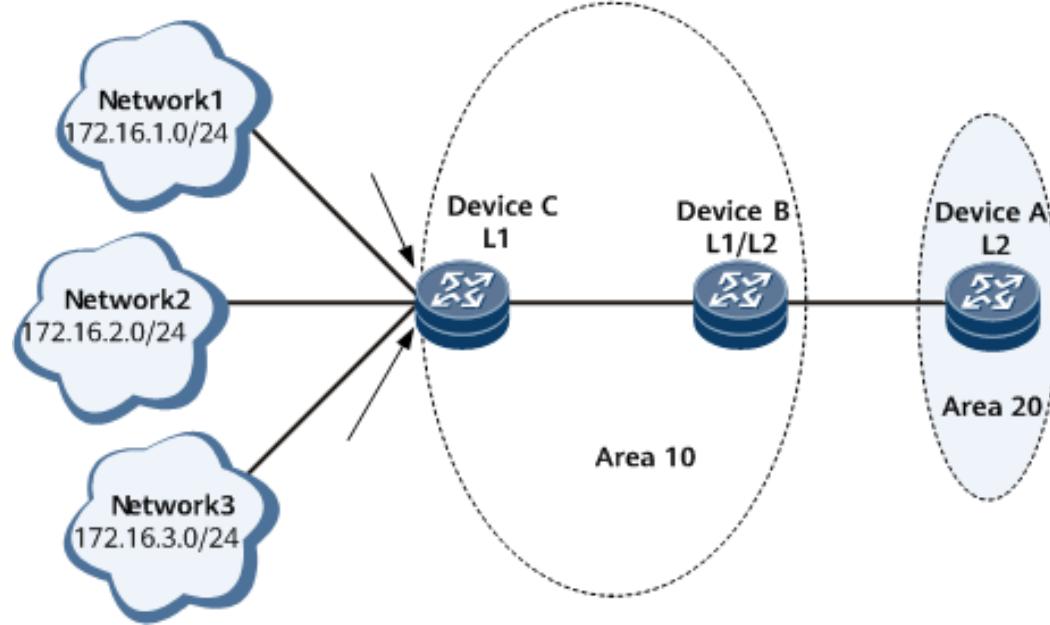

In this case, you can enable route leaking on the Level-1-2 devices (Device C and Device D). Then, check the route and you can find that the selected route is Device A -> Device B -> Device D -> Device E -> Device F.

### Route Summarization

On a large-scale IS-IS network, links connected to devices within an IP address range may alternate between up and down. With route summarization, multiple

routes with the same IP prefix are summarized into one route, which prevents route flapping, reduces routing entries and system resource consumption, and facilitates route management. [Figure 1-230](#) shows the typical networking.

[Figure 1-230](#) Typical networking for route summarization

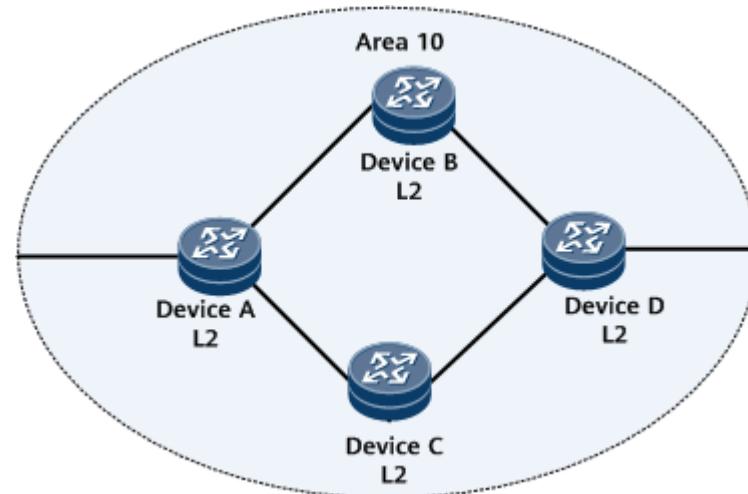

- router A, router B, and router C use IS-IS to communicate with each other.
- Device A belongs to area 20, and Device B and Device C belong to area 10.
- Device A is a Level-2 router. Device B is a Level-1-2 router. Device C is a Level-1 router.
- Device B maintains Level-1 and Level-2 LSDBs and leaks the routes to three network segments (172.16.1.0/24, 172.16.2.0/24, and 172.16.3.0/24) from the Level-1 area to the Level-2 area. If a link fault causes the Device C interface with IP address 172.16.1.1/24 to frequently alternate between up and down, the state change is advertised to the Level-2 area, triggering frequent LSP flooding and SPF calculation on Device A. As a result, the CPU usage on Device A increases, and even network flapping occurs.

If Device B is configured to summarize routes to the three network segments in the Level-1 area into route 172.16.0.0/22, the number of routing entries on Device B is reduced; in addition, the impact of link state changes in the Level-1 area on route convergence in the Level-2 area can be reduced.

## Load Balancing

When multiple equal-cost routes are available on a network, you can configure IS-IS load balancing to improve link utilization and prevent network congestion caused by link overload. IS-IS load balancing evenly distributes traffic among multiple equal-cost paths. [Figure 1-231](#) shows the typical networking for load balancing.

Figure 1-231 Typical networking for load balancing

- Device A, Device B, Device C, and Device D communicate with each other on an IP network using IS-IS.
- Device A, Device B, Device C, and Device D belong to area 10 and are Level-2 routers.
- If load balancing is not enabled, traffic on Device A is transmitted along the optimal route obtained using the SPF calculation. Consequently, traffic on different links is unbalanced. Enabling load balancing on Device A sends traffic to routerDevice D through routerDevice B and Device C. This transmission mode relieves the load on the optimal route.

Load balancing supports per-packet load balancing and per-flow load balancing. For details, see *NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X Feature Description - IP Routing*.

IS-IS supports not only intra-process load balancing, but also inter-process load balancing when equal-cost routes exist between different processes.

## Administrative Tag

Administrative tags carry administrative information about IP address prefixes. When the cost type is wide, wide-compatible, or compatible and the prefix of the reachable IP address to be advertised by IS-IS has this cost type, IS-IS adds the administrative tag to the reachability type-length-value (TLV) in the prefix. In this manner, the administrative tag is advertised to the entire routing domain along with the prefix so that routes can be imported or filtered based on the administrative tag.

## IS-IS Mesh Group

As defined in IS-IS, upon receipt of a new LSP, a router floods it. On a network with high connectivity and multiple P2P links, this causes repeated LSP flooding and wastes bandwidth resources. To prevent this problem, you can configure a mesh group to reduce bandwidth waste.

A mesh group consists of a group of interfaces. Interfaces in a mesh group flood the LSPs received from the local group only to the interfaces in other mesh groups

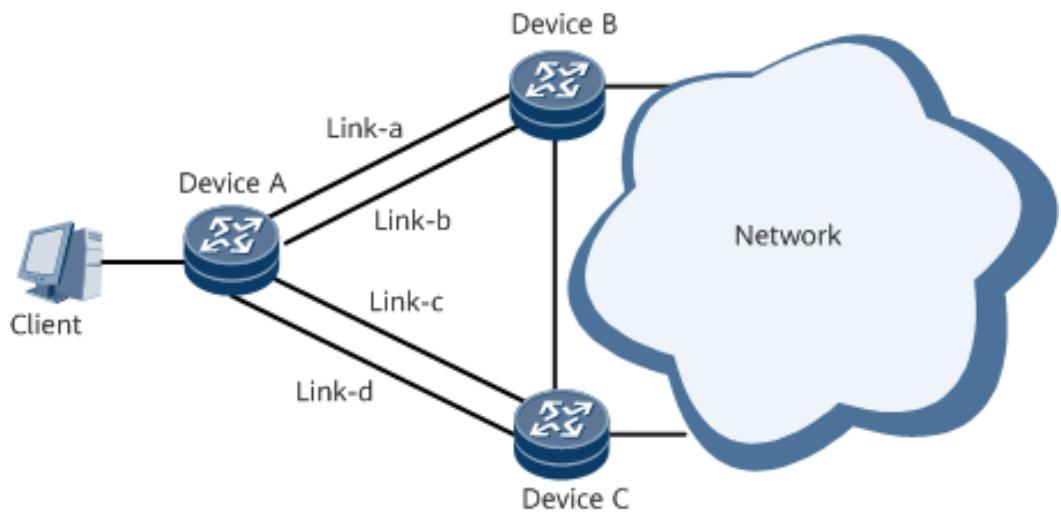

and those that are not in any mesh group. In addition, interfaces in a mesh group use the CSNP and PSNP mechanisms to implement LSDB synchronization in the entire network segment.

## link-group

In [Figure 1-232](#), router A is dual-homed to the IS-IS network through router B and router C. The path router A -> router B is primary and the path router A -> router C is backup. The bandwidth of each link is 100 Gbit/s, and the traffic from Client is transmitted at 150 Gbit/s. In this situation, both links in the path router A -> router B or the path router A -> router C need to carry the traffic. If Link-a fails, Link-b takes over all the traffic. However, the bandwidth of Link-b is not sufficient to carry the traffic. As a result, traffic loss occurs.

To address this problem, configure link groups. You can add multiple links to a link group. If one of the links fails and the bandwidth of the other links in the group is not sufficient to carry the traffic, the link group automatically increases the costs of the other links to a configured value so that this link group is not selected. Then, traffic is switched to another link group.

**Figure 1-232** IS-IS dual-homing access networking

In [Figure 1-232](#), Link-a and Link-b belong to link group 1, and Link-c and Link-d belong to link group 2.

- If Link-a fails, link group 1 automatically increases the cost of Link-b so that the traffic is switched to Link-c and Link-d.
- If both Link-a and Link-c fail, the link groups increase the costs of Link-b and Link-d (to the same value) so that Link-b and Link-d load-balance the traffic.

## IS-IS Neighbor Relationship Flapping Suppression

IS-IS neighbor relationship flapping suppression works by delaying neighbor relationship reestablishment or setting the link cost to the maximum value.

## Background

If the status of an interface carrying IS-IS services alternates between Up and Down, IS-IS neighbor relationship flapping occurs on the interface. During the

flapping, IS-IS frequently sends Hello packets to reestablish the neighbor relationship, synchronizes LSDBs, and recalculates routes. In this process, a large number of packets are exchanged, adversely affecting neighbor relationship stability, IS-IS services, and other IS-IS-dependent services, such as LDP and BGP. IS-IS neighbor relationship flapping suppression can address this problem by delaying IS-IS neighbor relationship reestablishment or preventing service traffic from passing through flapping links.

## Related Concepts

**Flapping\_event:** reported when the status of a neighbor relationship on an interface last changes from **Up** to **Init** or **Down**. The flapping\_event triggers flapping detection.

**Flapping\_count:** number of times flapping has occurred.

**Detect-interval:** interval at which flapping is detected. The interval is used to determine whether to trigger a valid flapping\_event.

**Threshold:** flapping suppression threshold. When the flapping\_count exceeds the threshold, flapping suppression takes effect.

**Resume-interval:** interval used to determine whether flapping suppression exits. If the interval between two valid flapping\_events is longer than the resume-interval, flapping suppression exits.

## Implementation

### Flapping detection

IS-IS interfaces start a flapping counter. If the interval between two consecutive flapping\_events is shorter than the detect-interval, a valid flapping\_event is recorded, and the flapping\_count increases by 1. When the flapping\_count reaches or exceeds the threshold, the system determines that flapping occurs, implements flapping suppression, and sets the flapping\_count to 0. If the interval between two valid flapping\_events is longer than the resume-interval before the flapping\_count reaches the threshold again, the system sets the flapping\_count to 0 again. Interfaces start the suppression timer when the status of a neighbor relationship last changes to **Init** or **Down**.

The detect-interval, threshold, and resume-interval are configurable.

### Flapping suppression

Flapping suppression works in either Hold-down or Hold-max-cost mode.

- Hold-down mode: In the case of frequent flooding and topology changes during neighbor relationship establishment, interfaces prevent neighbor relationships from being reestablished during the suppression period, which minimizes LSDB synchronization attempts and packet exchanges.
- Hold-max-cost mode: If the traffic forwarding path frequently changes, interfaces use the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) of the flapping link during the suppression period to prevent traffic from passing through the flapping link.

Flapping suppression can also work first in Hold-down mode and then in Hold-max-cost mode.

By default, IS-IS uses the Hold-max-cost mode. The mode and suppression period can be changed manually.

 **NOTE**

When an interface enters the flapping suppression state, all neighbor relationships on the interface enter the state accordingly.

### Exiting from flapping suppression

Interfaces exit from flapping suppression in the following scenarios:

- The suppression timer expires.
- The corresponding IS-IS process is reset.
- A command is run to exit from flapping suppression.
- Three Hello packets in which the padding TLV carries a sub-TLV with the value being 251 are sent consecutively to instruct the peer device to exit flapping suppression.

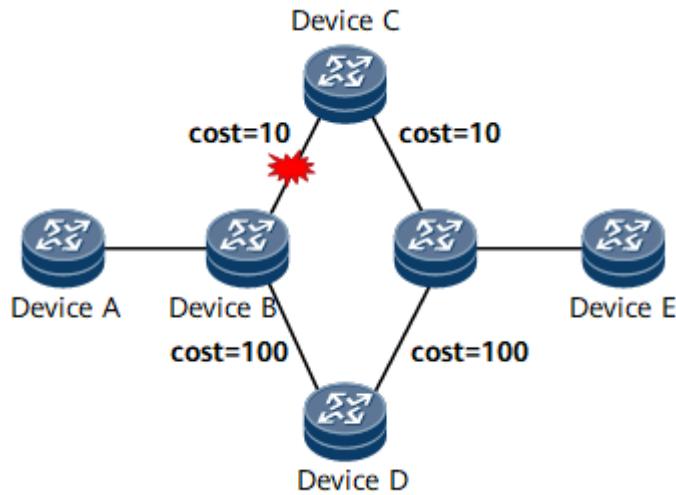

## Typical Usage Scenario

### Basic scenario

On the network shown in [Figure 1-233](#), the traffic forwarding path is Device A -> Device B -> Device C -> Device E before a link failure occurs. After the link between Device B and Device C fails, the forwarding path switches to Device A -> Device B -> Device D -> Device E. If the neighbor relationship between Device B and Device C frequently flaps at the early stage of the path switchover, the forwarding path for the traffic from Device A to Device E will be switched frequently, causing traffic loss and affecting network stability. If the neighbor flapping between Device B and Device C meets flapping suppression conditions, flapping suppression is triggered.

- If flapping suppression works in Hold-down mode, the neighbor relationship between Device B and Device C is prevented from being reestablished during the suppression period, in which traffic is forwarded along the path Device A -> Device B -> Device D -> Device E.
- If flapping suppression works in Hold-max-cost mode, the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) is used as the cost of the link between Device B and Device C during the suppression period, and traffic is forwarded along the path Device A -> Device B -> Device D -> Device E.

Figure 1-233 Flapping suppression in a basic scenario

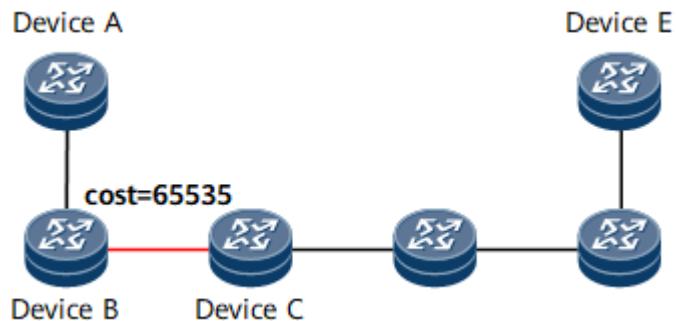

#### Single-forwarding path scenario

When only one forwarding path exists on the network, the flapping of the neighbor relationship between any two devices on the path will interrupt traffic forwarding. In [Figure 1-234](#), the only traffic forwarding path is Device A -> Device B -> Device C -> Device E. If the neighbor relationship between Device B and Device C flaps, and the flapping meets suppression conditions, flapping suppression takes effect. However, the link between Device B and Device C is a key link on the network. Once the link is disconnected, the entire network is divided into two networks that are not interconnected. Therefore, Hold-max-cost mode (rather than Hold-down mode) is recommended in this scenario. If flapping suppression works in Hold-max-cost mode, the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) is used as the cost of the link between Device B and Device C during the suppression period. After the network becomes stable and the suppression timer expires, flapping suppression exits automatically, and the service link recovers immediately.

#### NOTE

By default, the Hold-max-cost mode takes effect.

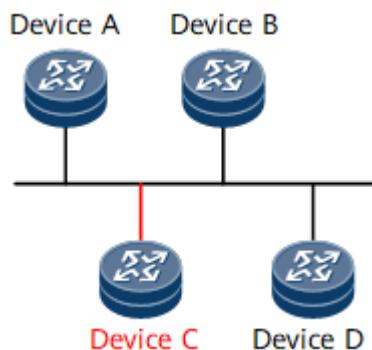

Figure 1-234 Flapping suppression in a single-forwarding path scenario

#### Broadcast scenario

In [Figure 1-235](#), four devices are deployed on the same broadcast network using switches, and the devices are broadcast network neighbors. If Device C keeps flapping due to a link failure, and Device A and Device B were deployed at different time (Device A was deployed earlier for example) or the flapping suppression parameters on Device A and Device B are different, Device A first detects the flapping and suppresses Device C. Consequently, the Hello packets sent by Device A do not carry Device C's router ID. However, Device B has not detected the flapping yet and still considers Device C a valid node. As a result, the DIS candidates identified by Device A are Device B and Device D, whereas the DIS candidates identified by Device B are Device A, Device C, and Device D. Different candidates result in different election results, which may lead to route calculation errors. In scenarios where an interface has multiple neighbors, such as on a broadcast, P2MP, or NBMA network, all neighbors on the interface are suppressed if the last flapping event that the neighbor status on the interface becomes Init or Down is detected (flapping detection cannot be performed by neighbor). Specifically, if Device C flaps, Device A, Device B, and Device D on the broadcast network are all suppressed. After the network stabilizes and the suppression timer expires, Device A, Device B, and Device D are restored to normal status.

**Figure 1-235** Flapping suppression on a broadcast network

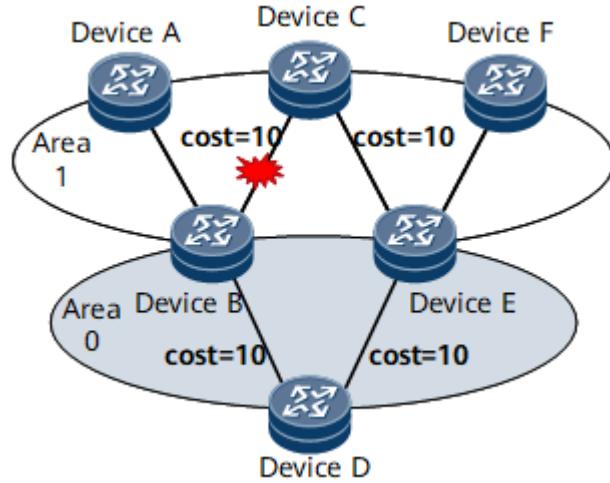

### Scenario of multi-level networking

In [Figure 1-236](#), Device A, Device B, Device C, Device E, and Device F are Level-1 neighbors in area 1. Device B, Device D, and Device E are Level-2 neighbors in area 0. Traffic from Device A to Device F is preferentially forwarded along an intra-area route, and the forwarding path is Device A -> Device B -> Device C -> Device E -> Device F. If the neighbor relationship between Device B and Device C flaps and the flapping meets suppression conditions, flapping suppression takes effect in the default mode (Hold-max-cost). However, the forwarding path remains unchanged (Device A -> Device B -> Device C -> Device E -> Device F) after the neighbor flapping occurs because intra-area routes take precedence over inter-area routes during route selection regardless of costs according to IS-IS route selection rules. The Hold-max-cost mode cannot suppress traffic path switching in this case. To prevent traffic loss in multi-area scenarios, configure Hold-down mode to prevent the neighbor relationship between Device B and Device C from being reestablished during the suppression period. During this period, traffic is forwarded along the path Device A -> Device B -> Device D -> Device E -> Device F.

 NOTE

By default, the Hold-max-cost mode is enabled for IS-IS. You can change the mode to Hold-down using a command.

**Figure 1-236 Flapping suppression in a multi-level scenario**

**Scenario with both LDP-IGP synchronization and neighbor relationship flapping suppression configured**

In [Figure 1-237](#), if the link between PE1 and P1 fails, an LDP LSP switchover is implemented immediately, causing the original LDP LSP to be deleted before a new LDP LSP is established. To prevent traffic loss, IGP-LDP synchronization needs to be configured. With IGP-LDP synchronization, the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) is used as the cost of the new LSP to be established. After the new LSP is established, the original cost takes effect. Consequently, the original LSP is deleted, and LDP traffic is forwarded along the new LSP.

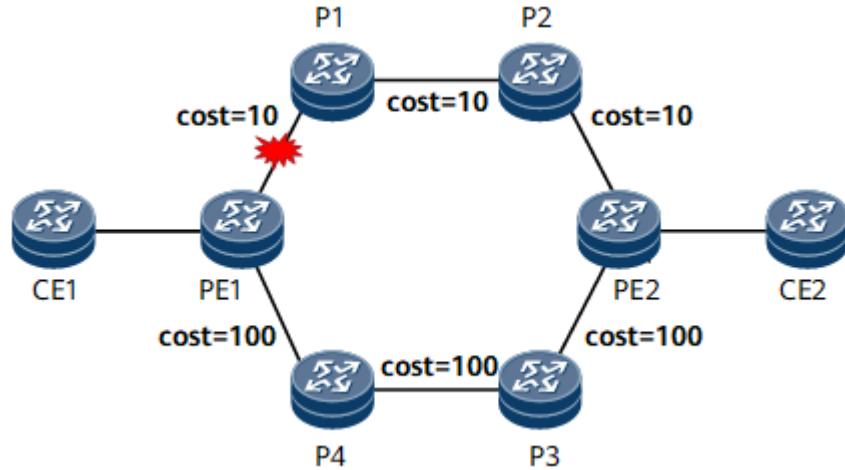

LDP-IGP synchronization and OSPF neighbor relationship flapping suppression work in either Hold-down or Hold-max-cost mode. If both functions are configured, Hold-down mode takes precedence over Hold-max-cost mode, followed by the configured link cost. [Table 1-82](#) lists the suppression modes that take effect in different situations.

**Table 1-82** Principles for selecting the suppression modes that take effect in different situations

| LDP-IGP Synchronization/IS-IS Neighbor Relationship Flapping Suppression Mode | LDP-IGP Synchronization Hold-down Mode | LDP-IGP Synchronization Hold-max-cost Mode | Exited from LDP-IGP Synchronization Suppression                                    |
|-------------------------------------------------------------------------------|----------------------------------------|--------------------------------------------|------------------------------------------------------------------------------------|
| IS-IS Neighbor Relationship Flapping Suppression Hold-down Mode               | Hold-down                              | Hold-down                                  | Hold-down                                                                          |
| IS-IS Neighbor Relationship Flapping Suppression Hold-max-cost Mode           | Hold-down                              | Hold-max-cost                              | Hold-max-cost                                                                      |
| Exited from IS-IS Neighbor Relationship Flapping Suppression                  | Hold-down                              | Hold-max-cost                              | Exited from LDP-IGP synchronization and neighbor relationship flapping suppression |

For example, the link between PE1 and P1 frequently flaps in [Figure 1-237](#), and both LDP-IGP synchronization and IS-IS neighbor relationship flapping suppression are configured. In this case, the suppression mode is selected based on the preceding principles. No matter which mode (Hold-down or Hold-max-cost) is selected, the forwarding path is PE1 -> P4 -> P3 -> PE2.

**Figure 1-237 Scenario with both LDP-IGP synchronization and neighbor relationship flapping suppression configured**

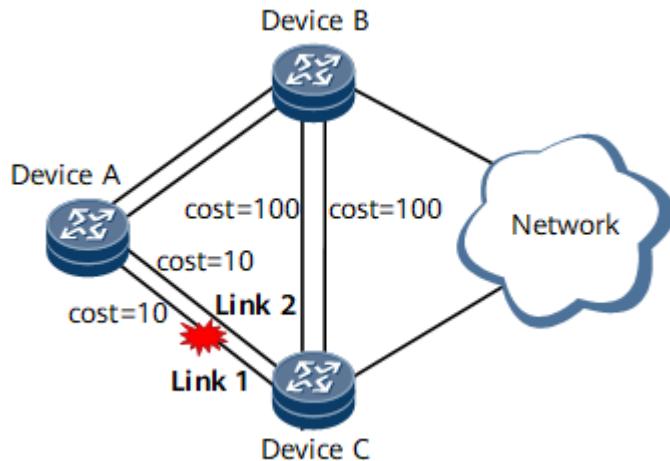

**Scenario with both bit-error-triggered protection switching and IS-IS neighbor relationship flapping suppression configured**

If a link has poor link quality, services transmitted along it may be adversely affected. If bit-error-triggered protection switching is configured and the bit error rate (BER) along a link exceeds a specified value, a bit error event is reported, and the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) is used as the cost of the link, triggering route reselection. Consequently, service traffic is switched to the backup link. If both bit-error-triggered protection switching and IS-IS neighbor relationship flapping suppression are configured, they both take effect. Hold-down mode takes precedence over Hold-max-cost mode, followed by the configured link cost.

**Scenario with both Link-bundle and IS-IS neighbor relationship flapping suppression configured**

When the service traffic rate exceeds the capacity of the link, multiple links must be used. In such cases, if one link fails, traffic is switched to another link and excess traffic is discarded due to the new link's limited forwarding capacity. Link-bundle can address this problem. If the number of faulty links reaches the upper threshold, the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) is used as the cost of all links in the link bundle to switch all service traffic to the backup nodes. If both link-bundle and neighbor relationship flapping suppression are configured and the number of flapping links reaches the upper threshold, the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) must be configured as the cost of all other links in the link bundle to prevent service loss caused by user traffic congestion. In [Figure 1-238](#), two parallel links forward traffic between Device A and Device C. If link 1 fails, link 2 is incapable of bearing all service traffic. If both link-bundle and neighbor relationship flapping suppression are configured and Link 1 flaps, the maximum cost (16777214 in IS-IS wide mode and 63 in IS-IS narrow mode) must be configured for Link 2 to avoid service traffic congestion. Only the Hold-max-cost mode therefore can be configured for neighbor relationship flapping suppression to switch the traffic forwarding path to Device A->Device B->Device C.

**Figure 1-238** Scenario with both Link-bundle and IS-IS neighbor relationship flapping suppression configured

## IS-IS Overload

The overload (OL) field of LSPs configured on a device prevents other devices from calculating the routes passing through this device.

If a system fails to store new LSPs for LSDB synchronization, the routes calculated by the system are incorrect. In that case, the system enters the Overload state. The user can configure the device to enter the Overload state when the system lacks sufficient memory. At present, users can set the Overload timer when IS-IS is started and configure whether to delete the leaked routes and whether to advertise the imported routes. A device enters the Overload state after an exception occurs on the device or when it is configured to enter the state.

- If IS-IS enters the Overload state after an exception occurs on the device, the system deletes all imported or leaked routes.
  - If IS-IS enters the Overload state based on a user configuration, the system only deletes all imported or leaked routes if configured to do so.

Although LSPs with overload fields are flooded throughout the network, they are ignored in the calculation of the routes passing through the device in the Overload state. Specifically, after the overload field of LSPs is configured on a device, other devices do not count the routes that pass through the device when performing SPF calculation, but the direct routes between the device and other devices are still calculated.

If a device in an IS-IS domain is faulty, routes may be incorrectly calculated across the entire domain. The overload field can be configured for the device to isolate it from the IS-IS network temporarily, which facilitates fault isolation.

## IS-IS Fast Convergence

IS-IS fast convergence is an extended feature of IS-IS implemented to speed up route convergence.

- Incremental SPF (I-SPF)

I-SPF recalculates only the routes of the changed nodes rather than the routes of all nodes when the network topology changes, which speeds up the calculation of routes.

- Partial Route Calculation (PRC)

PRC calculates only those routes which have changed when the network topology changes.

- Link State PDUs (LSP) fast flooding

LSP fast flooding speeds up LSP flooding.

- Intelligent timer

The first timeout period of the timer is fixed. If an event that triggers the timer occurs before the set timer expires, the next timeout period of the timer increases.

The intelligent timer applies to LSP generation and SPF calculation.

## I-SPF

In ISO 10589, the Dijkstra algorithm was adopted to calculate routes. When a node changes on the network, the algorithm recalculates all routes. The calculation requires a long time to complete and consumes a significant amount of CPU resources, reducing convergence speed.

I-SPF improves the algorithm. Except for the first time the algorithm is run, only the nodes that have changed rather than all nodes in the network are used in the calculation. The SPT generated using I-SPF is the same as that generated using the previous algorithm. This significantly decreases CPU usage and speeds up network convergence.

## PRC

Similar to I-SPF, PRC calculates only routes that have changed. PRC, however, does not calculate the shortest path. It updates routes based on the SPT calculated by I-SPF.

In route calculation, a leaf represents a route, and a node represents a device. Either an SPT change or a leaf change causes a routing information change. The SPT change is irrelevant to the leaf change. PRC processes routing information as follows:

- If the SPT changes after I-SPF calculation, PRC calculates all the leaves only on the changed node.
- If the SPT remains unchanged after I-SPF calculation, PRC calculates only the changed leaves.

For example, if a new route is imported, the SPT of the entire network remains unchanged. In this case, PRC updates only the interface route for this node, thereby reducing the CPU usage.

PRC working with I-SPF further improves network convergence performance and replaces the original SPF algorithm.

 NOTE

On the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X, only I-SPF and PRC are used to calculate IS-IS routes.

## LSP Fast Flooding

When an IS-IS device receives new LSPs from other devices, it updates the LSPs in the LSDB and periodically floods the updated LSPs based on a timer. Therefore, the synchronization of all LSDBs is slow.

LSP fast flooding can address this problem. With this function configured, when the router receives LSPs that can trigger route calculation or route update, the router makes its best efforts to flood these LSPs before route calculation is performed. This speeds up LSDB synchronization on the entire network. This flooding mode significantly speeds up the network-wide convergence speed.

 NOTE

LSP fast flooding is supported by default and does not need to be configured.

## Intelligent Timer

Although the route calculation algorithm is improved, the long interval for triggering route calculation also affects the convergence speed. A millisecond-level timer can shorten the interval. Frequent network changes, however, also consume too much CPU resources. The SPF intelligent timer can quickly respond to a few external emergencies and avoid excessive CPU usage.

In most cases, an IS-IS network running normally is stable. The frequent changes on a network are rather rare, and IS-IS does not calculate routes frequently. Therefore, a short period (within milliseconds) can be configured as the first interval for route calculation. If the network topology changes frequently, the interval set by the intelligent timer increases with the calculation times to reduce CPU consumption.

The LSP generation intelligent timer is similar to the SPF intelligent timer. When the LSP generation intelligent timer expires, the system generates a new LSP based on the current topology. In the original implementation mechanism, a timer with a fixed interval is used, which cannot meet the requirements of fast convergence and low CPU usage at the same time. Therefore, the LSP generation timer is designed as an intelligent timer to respond to emergencies (for example, the interface goes Up or Down) quickly and speed up network convergence. In addition, when the network changes frequently, the interval for the intelligent timer becomes longer to reduce CPU consumption.

## IS-IS LSP Fragment Extension

If the LSP capacity is insufficient, newly imported routes and new TLVs fail to be added to LSP fragments. In this case, you can use LSP fragment extension to increase the LSP capacity, restoring the LSP space. When the LSP space is restored, the system automatically attempts to re-add these routes and TLVs to LSP fragments.

When the LSPs to be advertised by IS-IS contain a large amount of information, they are advertised in multiple Link State PDUs (LSP) fragments belonging to the same system.

Virtual system IDs can be configured, and virtual LSPs that carry routing information can be generated for IS-IS.

IS-IS LSP fragment extension allows an IS-IS device to generate more LSP fragments and carry more IS-IS information.

## Terms

- Originating system

The originating system is a device that runs the IS-IS protocol. A single IS-IS process advertises LSPs as virtual devices do, except that the originating system refers to a real IS-IS process.

- Normal system ID

The normal system ID is the system ID of the originating system.

- Additional system ID

The additional system ID, assigned by the network administrator, is used to generate additional or extended LSP fragments. A maximum of 256 additional or extended LSP fragments can be generated. Like a normal system ID, an additional system ID must be unique in a routing domain.

- Virtual system

The virtual system, identified by an additional system ID, is used to generate extended LSP fragments. These fragments carry additional system IDs in their LSP IDs.

## Principles

IS-IS LSP fragments are identified by the LSP Number field in their LSP IDs. The LSP Number field is 1 byte. Therefore, an IS-IS process can generate a maximum of 256 fragments. With fragment extension, more information can be carried.

Each system ID represents a virtual system, and each virtual system can generate 256 LSP fragments. In addition, another virtual systems can be configured. Therefore, an IS-IS process can generate more LSP fragments.

After a virtual system and fragment extension are configured, an IS-IS device adds the contents that cannot be contained in its LSPs to the LSPs of the virtual system and notifies other devices of the relationship between the virtual system and itself through a special TLV in the LSPs.

## IS Alias ID TLV

Standard protocol defines a special Type-Length-Value (TLV): IS Alias ID TLV.

**Table 1-83 IS Alias ID TLV**

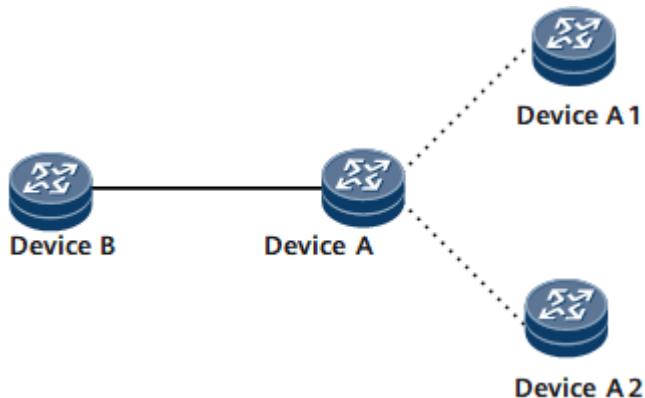

| Field             | Length         | Description                                                     |
|-------------------|----------------|-----------------------------------------------------------------|
| Type              | 1 byte         | TLV type. If the value is 24, it indicates the IS Alias ID TLV. |
| Length            | 1 byte         | TLV length.                                                     |
| System ID         | 6 bytes        | System ID.                                                      |
| Pseudonode number | 1 byte         | Pseudonode number.                                              |
| Sub-TLVs length   | 1 byte         | Length of sub-TLVs.                                             |
| Sub-TLVs          | 0 to 247 bytes | Sub-TLVs.                                                       |

LSPs with fragment number 0 sent by the originating system and virtual system carry IS Alias ID TLVs to indicate the originating system.

## Operation Modes

IS-IS devices can use the LSP fragment extension feature in the following modes:

**Figure 1-239 Networking for IS-IS LSP fragment extension**

- Mode-1

Mode-1 is used when some devices on the network do not support LSP fragment extension.

In this mode, virtual systems participate in SPF calculation. The originating system advertises LSPs containing information about links to each virtual system and each virtual system advertises LSPs containing information about links to the originating system. In this manner, the virtual systems function the same as the actual devices connected to the originating system on the network.

Mode-1 is a transitional mode for earlier versions that do not support LSP fragment extension. In the earlier versions, IS-IS cannot identify Alias ID TLVs. Therefore, the LSP sent by a virtual system must look like a common IS-IS LSP.

The LSP sent by a virtual system contains the same area address and overload bit as those in the common LSP. If the LSPs sent by a virtual system contain TLVs specified in other features, the TLVs must be the same as those in common LSPs.

LSPs sent by a virtual system carry information of the neighbor (the originating system), and the carried cost is the maximum value minus 1. LSPs sent by the originating system carry information of the neighbor (the virtual system), and the carried cost is 0. This mechanism ensures that the virtual system is a node downstream of the originating system when other devices calculate routes.

In [Figure 1-239](#), Device B does not support LSP fragment extension; Device A supports LSP fragment extension in mode-1; Device A1 and Device A2 are virtual systems of Device A. Device A1 and Device A2 send LSPs carrying partial routing information of Device A. After receiving LSPs from Device A, Device A1, and Device A2, Device B considers there to be three devices at the peer end and calculates routes normally. Because the cost of the route from Device A to Device A1 or Device A2 is 0, the cost of the route from Device B to Device A is equal to that from Device B to Device A1.

- Mode-2

Mode-2 is used when all the devices on the network support LSP fragment extension. In this mode, virtual systems do not participate in SPF calculation. All the devices on the network know that the LSPs generated by the virtual systems actually belong to the originating system.

IS-IS working in mode-2 identifies IS Alias ID TLVs, which are used to calculate the SPT and routes.

In [Figure 1-239](#), Device B supports LSP fragment extension, and Device A supports LSP fragment extension in mode-2; Device A1 and Device A2 send LSPs carrying some routing information of Device A. After receiving LSPs from Device A1 and Device A2, Device B obtains IS Alias ID TLV and learns that the originating system of Device A1 and Device A2 is Device A. Device B then considers information advertised by Device A1 and Device A2 to be about Device A.

Whatever the LSP fragment extension mode, LSPs can be resolved. However, if LSP fragment extension is not supported, only LSPs in mode-1 can be resolved.

**Table 1-84** Comparison between mode-1 and mode-2

| LSP Field              | Carried in Mode-1 | Carried in Mode-2 |
|------------------------|-------------------|-------------------|
| IS Alias ID            | Yes               | Yes               |
| Area                   | Yes               | No                |
| Overload bit           | Yes               | Yes               |
| IS NBR/IS EXTENDED NBR | Yes               | No                |

| LSP Field | Carried in Mode-1 | Carried in Mode-2 |
|-----------|-------------------|-------------------|
| Routing   | Yes               | Yes               |
| ATT bit   | Yes, with value 0 | Yes, with value 0 |
| P bit     | Yes, with value 0 | Yes, with value 0 |

## Process

After LSP fragment extension is configured, if information is lost because LSPs overflow, the system restarts the IS-IS process. After being restarted, the originating system loads as much routing information as possible. Any excessive information beyond the forwarding capability of the system is added to the LSPs of the virtual systems for transmission. In addition, if a virtual system with routing information is deleted, the system automatically restarts the IS-IS process.

## Usage Scenario

### NOTE

If there are non-Huawei devices on the network, LSP fragment extension must be set to mode-1. Otherwise, these devices cannot identify LSPs.

Configuring LSP fragment extension and virtual systems before setting up IS-IS neighbors or importing routes is recommended. If IS-IS neighbors are set up or routes are imported first and the information to be carried exceeds the forwarding capability of 256 fragments before LSP fragment extension and virtual systems are configured, you have to restart the IS-IS process for the configurations to take effect.

## IS-IS 3-Way Handshake

IS-IS introduces the 3-way handshake mechanism on P2P links to ensure a reliable data link layer.

Based on ISO 10589, the IS-IS 2-way handshake mechanism uses Hello packets to set up P2P adjacencies between neighboring devices. When a device receives a Hello packet from the other end, it regards the other end as Up and sets up an adjacency with it. However, this mechanism has some serious shortcomings.

When two or more links exist between two devices, an adjacency can still be set up where one link is Down and the other is Up in the same direction. The parameters of the other link are used in SPF calculation. As a result, a device that does not detect any fault along the faulty link will continue trying to forward packets over the link.

The 3-way handshake mechanism resolves these problems on P2P links. In 3-way handshake mode, a device regards a neighbor Up and sets up an adjacency with it only after confirming that the neighbor has received the packet that the device sends.

In addition, the 3-way handshake mechanism uses the 32-bit Extended Local Circuit ID field, which extends the original 8-bit Extended Local Circuit ID field and the limit of only 255 P2P links.

 NOTE

By default, the IS-IS 3-way handshake mechanism is implemented on P2P links.

## IS-IS Extended Prefix Attribute

IS-IS defines a type of extended prefix attribute (IPv4/IPv6 Extended Reachability Attribute) sub-TLVs. These sub-TLVs are used to describe the origin of advertised routes and can be advertised in IPv4, IPv6, and locator TLVs. Based on the advertised sub-TLVs, the device can determine whether the received routes are inter-domain routes or host routes.

The extended prefix attribute flag (IPv4/IPv6 Extended Reachability Attribute Flags) is a part of the extended prefix attribute sub-TLV. The specific composition is as follows:

**Figure 1-240** Format of the IPv4/IPv6 Extended Reachability Attribute Flags sub-TLV

**Table 1-85** describes the fields of the extended prefix attribute flag.

**Table 1-85** Description of fields in the IPv4/IPv6 Extended Reachability Attribute Flags sub-TLV

| Field | Length | Meaning                                                                                                                                                                                                                                                                                                                                                                          |
|-------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X     | 1 bit  | External prefix flag: <ul style="list-style-type: none"><li>This flag indicates whether the prefix is imported from another protocol or IS-IS process and re-advertised.</li><li>The value of this flag remains unchanged during inter-level leaking.</li><li>For an IPv6 prefix, the X flag is not set to 1 because the parent TLV has a flag with the same function.</li></ul> |
| R     | 1 bit  | Re-advertisement flag: <ul style="list-style-type: none"><li>This flag is set to 1 when routes leak from a Level-1 area to a Level-2 area or from a Level-2 area to a Level-1 area on an IS-IS Level-1-2 device.</li><li>When local direct routes leak, this flag is not set to 1.</li></ul>                                                                                     |

| Field | Length | Meaning                                                                                                                                                                                                                                                                                                                                                                       |

You can run a command to determine whether to set this flag.</li><li>• The setting of this flag is kept when routes are leaked on an IS-IS Level-1-2 device.</li></ul> |

## IS-IS NSR

### Background

As networks develop, the demand for data, audio, and video services is growing, which imposes increasing requirements on IP network reliability. If an AMB/SMB switchover is performed on a device due to a maintenance operation or a single point of failure, routes may fail to converge, which may result in traffic loss or even a network breakdown. Non-stop routing (NSR) can address this problem and ensure uninterrupted forwarding of key services.

### Related Concepts

- High availability (HA): supports data backup between the AMB and SMB.
- Non-stop forwarding (NSF): enables a node to use the GR mechanism to ensure uninterrupted transmission during an AMB/SMB switchover.
- NSR: allows a standby control plane to take over traffic from an active control plane if the active control plane fails, preventing the control planes of neighbors from detecting the fault.
- AMB and SMB: run control plane processes.

### Implementation

With IS-IS NSR, IS-IS real-time data is synchronized between the AMB and SMB. After an AMB/SMB switchover is performed on a device, the SMB takes over services from the AMB, and neighbors are unaware of the local fault. After the switchover, the new AMB restores IS-IS immediately based on the synchronized IS-IS real-time data. Therefore, neighbors are unaware of the switchover as well. IS-IS NSR requires synchronization of the following data:

- All configuration data, such as information about neighbors, timer parameters, and process configurations.
- Dynamic data, such as the interface parameters and state, and information about neighbors and the link state database (LSDB).

For details about NSR, see *Feature Description - Reliability*.

## Usage Scenario

NSR minimizes the impact of control plane faults and prevents route flapping on networks that require high reliability.

## Benefits

NSR improves network reliability and ensures uninterrupted traffic forwarding.

## IS-IS for IPv6

Standard protocols released by the IETF defines two new TLVs that can support IPv6 routes and a new Network Layer Protocol Identifier (NLPID), which ensures that IS-IS can process and calculate IPv6 routes.

The two new TLVs are as follows:

- IPv6 Reachability

The IPv6 Reachability TLV indicates the reachability of a network by specifying the route prefix and metric. The type value is 236 (0xEC).

- IPv6 Interface Address

The IPv6 Interface Address TLV is similar to the IP interface address TLV of IPv4 in function, except that it changes the original 32-bit IPv4 address to a 128-bit IPv6 address. The type value is 232 (0xE8).

The NLPID is an 8-bit field that identifies network layer protocol packets. The NLPID of IPv6 is 142 (0x8E). If an IS-IS router supports IPv6, it advertises routing information through the NLPID value.

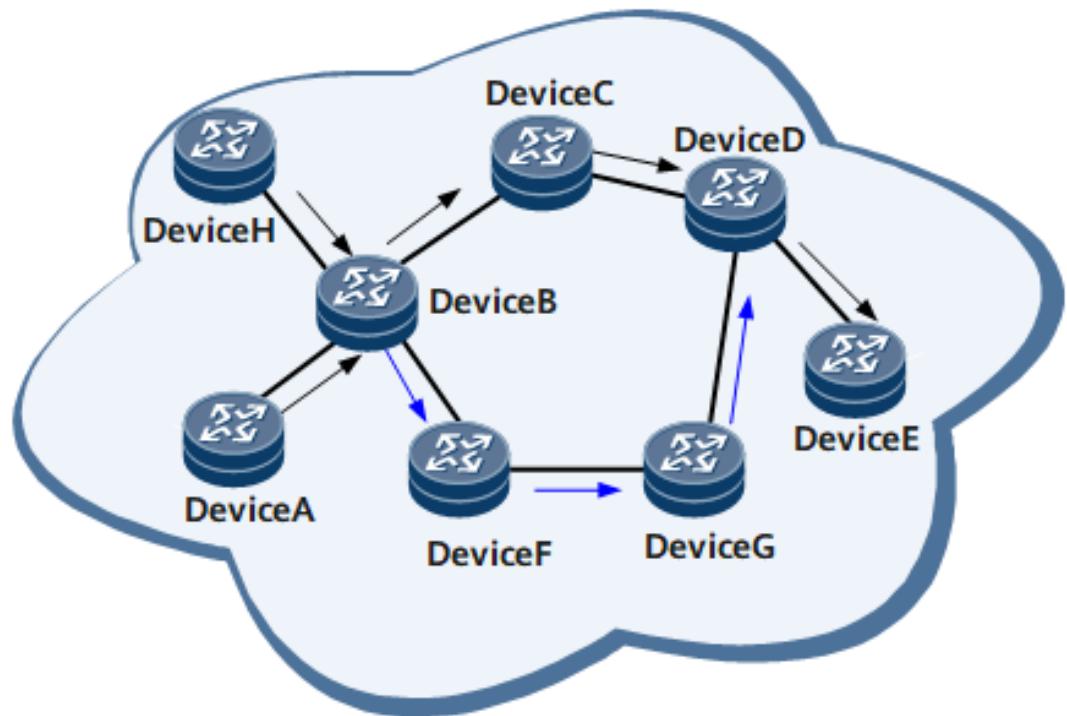

## IS-IS TE

IS-IS Traffic Engineering (TE) allows MPLS to set up and maintain TE constraint-based routed label switched paths (CR-LSPs).

To establish CR-LSPs, MPLS needs to learn the traffic attributes of all the links in the local area. MPLS can acquire the TE information of the links through IS-IS.

Traditional routers select the shortest path as the primary route regardless of other factors, such as bandwidth, even when the path is congested.

Figure 1-241 Networking with IS-IS routing defects

On the network shown in [Figure 1-241](#), all the links have the same metric (10). The shortest path from DeviceA/DeviceH to DeviceE is DeviceA/DeviceH → DeviceB → DeviceC → DeviceD → DeviceE. Data is forwarded along this shortest path. Therefore, the link DeviceA (DeviceH) → DeviceB → DeviceC → DeviceD → DeviceE may be congested whereas the link DeviceA/DeviceH → DeviceB → DeviceF → DeviceG → DeviceD → DeviceE is idle.

To solve the preceding problem, you can adjust the link metric. For example, based on topology analysis, you can adjust the metric of the link DeviceB → DeviceC to 30. In this manner, traffic can be diverted to the link DeviceA/DeviceH → DeviceB → DeviceF → DeviceG → DeviceD → DeviceE.

This method eliminates the congestion on the link DeviceA/DeviceH → DeviceB → DeviceC → DeviceD → DeviceE; however, the other link DeviceA/DeviceH → DeviceB → DeviceF → DeviceG → DeviceD → DeviceE may be congested. In addition, on a network with complex topologies, it is difficult to adjust the metric because the change in the metric of one link may affect multiple routes.

As an overlay model, MPLS can set up a virtual topology over the physical network topology and map traffic to the virtual topology, effectively combining MPLS and TE technology into MPLS TE.

MPLS TE has advantages in solving the problem of network congestion. Through MPLS TE, carriers can precisely control the path through which traffic passes, thus avoiding congested nodes. In addition, MPLS TE reserves resources during tunnel establishment to ensure service quality.

To ensure service continuity, MPLS TE introduces the path backup and fast reroute (FRR) mechanisms to switch traffic in time when a link is faulty. MPLS TE allows

service providers (SPs) to fully utilize existing network resources to provide diversified services. In addition, network resources can be optimized for scientific network management.

To accomplish the preceding tasks, MPLS TE needs to learn TE information about all devices on the network. However, MPLS TE lacks a mechanism in which each device floods its TE information throughout the entire network for TE information synchronization. However, IS-IS does provide such a mechanism. Therefore, MPLS TE can advertise and synchronize TE information with the help of IS-IS. To support MPLS TE, IS-IS needs to be extended.

In brief, IS-IS TE collects TE information on IS-IS networks and then transmits the TE information to the Constrained Shortest Path First (CSPF) module.

 NOTE

Currently, IS-IS TE supports only IPv4.

## Basic Principles

IS-IS TE is an extension of IS-IS intended to support MPLS TE. As defined in standard protocols, IS-IS TE uses LSPs to carry TE information to help MPLS implement the flooding, synchronization, and resolution of TE information. Then, IS-IS TE transmits the resolved TE information to the CSPF module. In MPLS TE, IS-IS TE plays the role of a porter. [Figure 1-242](#) illustrates the relationships between IS-IS TE, MPLS TE, and CSPF.

**Figure 1-242** Outline of relationships between MPLS TE, CSPF, and IS-IS TE

To carry TE information in LSPs, IS-IS TE defines the following TLVs in standard protocols:

- Extended IS reachability TLV

This TLV replaces the IS reachability TLV and extends the TLV format using sub-TLVs. The implementation of the sub-TLVs in the TLV is the same as that of TLVs in LSPs. These sub-TLVs are used to carry TE information configured on physical interfaces.

 NOTE

All sub-TLVs defined in standard protocols are supported.

**Table 1-86** Sub-TLVs defined in Extended IS reachability TLV

| Name                                      | Type | Length (Byte) | Value                                     |
|-------------------------------------------|------|---------------|-------------------------------------------|
| Administrative Group                      | 3    | 4             | Administrative group                      |
| IPv4 Interface Address                    | 6    | 4             | IPv4 address of a local interface         |
| IPv4 Neighbour Address                    | 8    | 4             | IPv4 address of a neighbor's interface    |
| Maximum Link Bandwidth                    | 9    | 4             | Maximum link bandwidth                    |
| Maximum Reserved Link Bandwidth           | 10   | 4             | Maximum reserved link bandwidth           |
| Unreserved Bandwidth                      | 11   | 32            | Unreserved bandwidth                      |
| Traffic Engineering Default Metric        | 18   | 3             | Default metric of TE                      |
| Bandwidth Constraints sub-TLV             | 22   | 36            | Sub-TLV of the bandwidth constraint.      |
| Unidirectional Link Delay Sub-TLV         | 33   | 4             | Average unidirectional link delay         |
| Min/Max Unidirectional Link Delay Sub-TLV | 34   | 8             | Minimum/Maximum unidirectional link delay |
| Unidirectional Delay Variation Sub-TLV    | 35   | 4             | Unidirectional link delay jitter          |

- Traffic Engineering router ID TLV  
The type of this TLV is 134, and this TLV carries a 4-byte router ID (MPLS LSR-ID). In MPLS TE, each device has a unique router ID.
- Extended IP reachability TLV  
This TLV replaces the IP reachability TLV and carries routing information. It extends the length of the route cost field to 4 bytes and carries sub-TLVs.

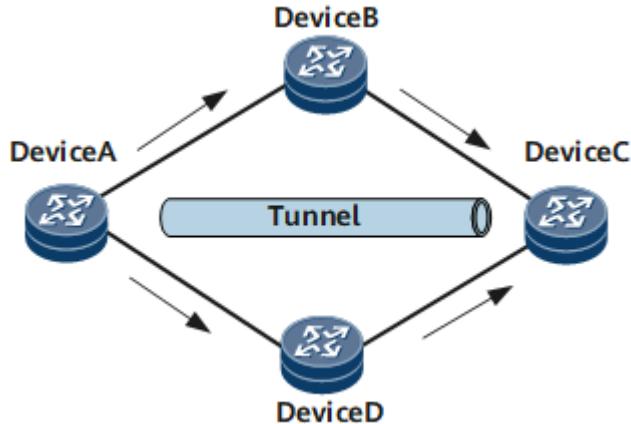

IS-IS TE consists of two procedures:

- Responding to MPLS TE configurations  
IS-IS TE functions only after MPLS TE is enabled.  
It updates the TE information in IS-IS LSPs based on MPLS TE configurations.  
It transmits MPLS TE configurations to the CSPF module.
- Processing TE information in LSPs  
It extracts TE information from IS-IS LSPs and transmits the TE information to the CSPF module.

## Usage Scenario

IS-IS TE helps MPLS TE set up TE tunnels. In [Figure 1-243](#), a TE tunnel is set up between Device A and Device C.

**Figure 1-243** Networking for IS-IS TE

The configuration requirements are as follows:

- MPLS TE and MPLS TE CSPF are enabled on Device A.
- MPLS TE is enabled on Device B, Device C, and Device D.
- IS-IS and IS-IS TE are enabled on Device A, Device B, Device C, and Device D.

After the configurations are complete, IS-IS on Device A, Device B, Device C, and Device D sends LSPs carrying TE information configured on each device. Device A obtains the MPLS TE configurations of DeviceB, DeviceC, and DeviceD from the received LSPs. In this way, Device A obtains the TE information of the entire network. The CSPF module can use the information to calculate the path required by the tunnel.

## IS-IS Wide Metric

In the earlier ISO 10589, the largest metric of an interface is 63. TLV type 128 and TLV type 130 contain information about routes, and TLV type 2 contains information about IS-IS neighbors. However, on large-scale networks, the metric range cannot meet the requirements. Moreover, IS-IS TE needs to be configured. Therefore, the wide metric was introduced.

As defined in standard protocols, with IS-IS wide metric, the largest metric of an interface is extended to 16777215, and the largest metric of a route is 4261412864.

After IS-IS wide metric is enabled, TLV type 135 contains information about routes; TLV type 22 contains information about IS-IS neighbors.

- The following lists the TLVs used in narrow mode:
  - IP Internal Reachability TLV: carries routes within an area.
  - IP External Reachability TLV: carries routes outside an area.

- IS Neighbors TLV: carries information about neighbors.
- The following lists the TLVs used in wide mode:
  - Extended IP Reachability TLV: replaces the earlier IP Reachability TLV and carries information about routes. This TLV expands the range of the route cost to 4 bytes and carries sub-TLVs.
  - IS Extended Neighbors TLV: carries information about neighbors.

 **NOTE**

The metric style can be set to narrow, narrow-compatible, compatible, wide-compatible, or wide mode. **Table 1-87** shows which metric styles are carried in received and sent packets. A device can calculate routes only when it can receive, send, and process corresponding TLVs. Therefore, to ensure correct data forwarding on a network, the proper metric style must be configured for each device on the network.

**Table 1-87** Metric style carried in received and sent under different metric style configurations

| Configured Metric Style | Metric Style Carried in Received Packets | Metric Style Carried in Sent Packets |
|-------------------------|------------------------------------------|--------------------------------------|
| Narrow                  | Narrow                                   | Narrow                               |
| Narrow-compatible       | Narrow and wide                          | Narrow                               |
| Compatible              | Narrow and wide                          | Narrow and wide                      |
| Wide-compatible         | Narrow and wide                          | Wide                                 |
| Wide                    | Wide                                     | Wide                                 |

When the metric style is set to compatible, IS-IS sends the information both in narrow and wide modes.

## Process

**NOTICE**

Once the metric style is changed, the IS-IS process restarts.

- If the metric style carried in sent packets is changed from narrow to wide:  
The information previously carried by TLV type 128, TLV type 130, and TLV type 2 is now carried by TLV type 135 and TLV type 22.
- If the metric style carried in sent packets is changed from wide to narrow:  
The information previously carried by TLV type 135 and TLV type 22 is now carried by TLV type 128, TLV type 130, and TLV type 2.
- If the metric style carried in sent packets is changed from narrow or wide to narrow and wide:  
The information previously carried in narrow or wide mode is now carried by TLV type 128, TLV type 130, TLV type 2, TLV type 135, and TLV type 22.

## Usage Scenario

IS-IS wide metric is used to support IS-IS TE, and the metric style needs to be set to wide, compatible or wide compatible.

## BFD for IS-IS

In most cases, the interval at which Hello packets are sent is 10s, and the IS-IS neighbor holding time (the timeout period of a neighbor relationship) is three times the interval. If a device does not receive a Hello packet from its neighbor within the holding time, the device terminates the neighbor relationship.

A device can detect neighbor faults at the second level only. As a result, link faults on a high-speed network may cause a large number of packets to be discarded.

BFD, which can be used to detect link faults on lightly loaded networks at the millisecond level, is introduced to resolve the preceding issue. With BFD, two systems periodically send BFD packets to each other. If a system does not receive BFD packets from the other end within a specified period, the system considers the bidirectional link between them Down.

BFD is classified into the following modes:

- Static BFD

In static BFD mode, BFD session parameters (including local and remote discriminators) are set using commands, and requests must be delivered manually to establish BFD sessions.

- Dynamic BFD

In dynamic BFD mode, the establishment of BFD sessions is triggered by routing protocols.

BFD for IS-IS enables BFD sessions to be dynamically established. After detecting a fault, BFD notifies IS-IS of the fault. IS-IS sets the neighbor status to Down, quickly updates link state protocol data units (LSPs), and performs the partial route calculation (PRC). BFD for IS-IS implements fast IS-IS route convergence.

### NOTE

Instead of replacing the Hello mechanism of IS-IS, BFD works with IS-IS to rapidly detect the faults that occur on neighboring devices or links.

## BFD Session Establishment and Deletion

- Conditions for establishing a BFD session
  - Global BFD is enabled on each device, and BFD is enabled on a specified interface or process.
  - IS-IS is configured on each device and enabled on interfaces.
  - Neighbors are Up, and a designated intermediate system (DIS) has been elected on a broadcast network.
- Process of establishing a BFD session
  - P2P network

After the conditions for establishing BFD sessions are met, IS-IS instructs the BFD module to establish a BFD session and negotiate BFD parameters between neighbors.

- Broadcast network

After the conditions for establishing BFD sessions are met and the DIS is elected, IS-IS instructs BFD to establish a BFD session and negotiate BFD parameters between the DIS and each device. No BFD sessions are established between non-DISs.

On broadcast networks, devices (including non-DIS devices) of the same level on a network segment can establish adjacencies. In BFD for IS-IS, however, BFD sessions are established only between the DIS and non-DISs. On P2P networks, BFD sessions are directly established between neighbors.

If a Level-1-2 neighbor relationship is set up between the devices on both ends of a link, the following situations occur:

- On a broadcast network, IS-IS sets up a Level-1 BFD session and a Level-2 BFD session.
- On a P2P network, IS-IS sets up only one BFD session.

- Process of tearing down a BFD session

- P2P network

If the neighbor relationship established between P2P IS-IS interfaces is not Up, IS-IS tears down the BFD session.

- Broadcast network

If the neighbor relationship established between broadcast IS-IS interfaces is not Up or the DIS is reelected on the broadcast network, IS-IS tears down the BFD session.

If the configurations of dynamic BFD sessions are deleted or BFD for IS-IS is disabled from an interface, all Up BFD sessions established between the interface and its neighbors are deleted. If the interface is a DIS and the DIS is Up, all BFD sessions established between the interface and its neighbors are deleted.

If BFD is disabled from an IS-IS process, BFD sessions are deleted from the process.

 NOTE

BFD detects only the one-hop link between IS-IS neighbors because IS-IS establishes only one-hop neighbor relationships.

- Response to the Down event of a BFD session

When BFD detects a link failure, it generates a Down event and informs IS-IS. IS-IS then suppresses neighbor relationships and recalculates routes. This process speeds up network convergence.

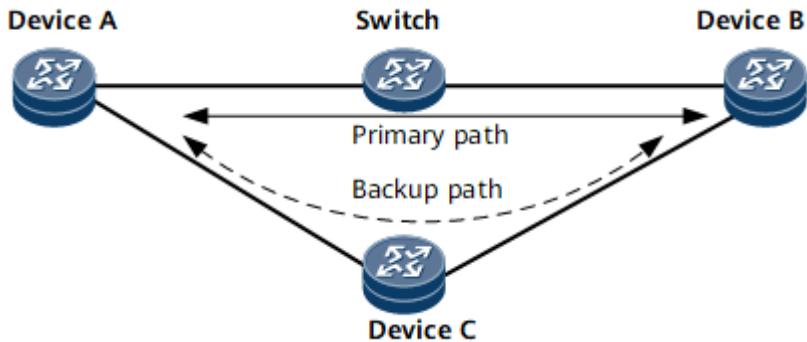

## Usage Scenario

**NOTICE**

Dynamic BFD needs to be configured based on the actual network. If the time parameters are not configured correctly, network flapping may occur.

BFD for IS-IS speeds up route convergence through rapid link failure detection. The following is a networking example for BFD for IS-IS.

Figure 1-244 BFD for IS-IS

The configuration requirements are as follows:

- Basic IS-IS functions are configured on each device shown in [Figure 1-244](#).
- Global BFD is enabled.
- BFD for IS-IS is enabled on Device A and Device B.

If the link between Device A and Device B fails, BFD can rapidly detect the fault and report it to IS-IS. IS-IS sets the neighbor status to Down to trigger an IS-IS topology calculation. IS-IS also updates LSPs so that Device C can promptly receive the updated LSPs from Device B, which accelerates network topology convergence.

## IS-IS Auto FRR

### Background

As networks develop, services such as Voice over IP (VoIP) and online video services require high-quality and real-time transmission. However, if a link fails, IS-IS must complete the following procedure before switching traffic to a new link: detect the fault, update LSPs, flood LSPs, calculate routes, and deliver route entries to the FIB. This is a lengthy process, and the associated traffic interruption is often longer than users can tolerate. As a result, real-time transmission requirements cannot be met.

IS-IS Auto FRR (Fast reroute) is dynamic IP FRR. An IGP pre-calculates a backup path based on the LSDBs on the entire network and saves the backup path in the forwarding table for traffic protection in the case of a fault. Because IP FRR helps implement fast route convergence, it becomes increasingly popular with carriers.

Currently, main FRR technologies include LFA, U-turn, Not-Via, TI-LFA, Remote-LFA, and MRT, among which IS-IS only supports LFA, TI-LFA, and Remote-LFA.

### Related Concepts

#### LFA

LFA is an IP FRR technology that calculates the shortest path from the neighbor that can provide a backup link to the destination node based on the Shortest Path First (SPF) algorithm. Then, LFA calculates a loop-free backup link with the smallest cost based on the inequality:

Distance<sub>opt</sub> (N, D) < Distance<sub>opt</sub> (N, S) + Distance<sub>opt</sub> (S, D), in which S, D, and N indicate the source node, destination node, and a node on the backup link, respectively, and Distance<sub>opt</sub> (X, Y) indicates the shortest distance from node X to node Y.

### P space

The P space is a set of nodes reachable from the source node of the primary link using the shortest path tree (SPT) rooted at the source node without traversing the primary link.

### Extended P space

Extended P space consists of the nodes through which the SPTs with neighbors of a primary link's source node as the root are reachable without passing through the primary link.

### Q space

The Q space is a set of nodes reachable from the destination node using the reverse SPT rooted at the destination node without traversing the primary link.

### PQ node

The nodes in both the extended P space and Q space are PQ nodes and are used as the destinations of protection tunnels in remote LFA.

### Remote LFA

LFA FRR cannot be used to calculate backup links on some large-scale networks, especially on ring networks. Remote LFA FRR addresses this problem by calculating a PQ node and establishing a tunnel between the source node and the PQ node as a backup path. If the primary link fails, traffic can be automatically switched to the backup path, which improves network reliability.

#### NOTE

When calculating an RLFA FRR backup path, a Huawei device calculates the extended P space by default.

### TI-LFA

In some LFA FRR and RLFA scenarios, the extended P space and Q space neither intersect nor have direct neighbors. Consequently, no backup path can be computed, failing to meet reliability requirements. TI-LFA solves this problem by computing the extended P space, Q space, and post-convergence SPT based on the protected path, computing a scenario-specific repair list, and establishing an SR tunnel from the source node to a P node and then to a Q node to offer alternate next hop protection. If the protected link fails, traffic is automatically switched to the backup path, improving network reliability.

#### NOTE

When computing a TI-LFA FRR backup path, Huawei devices compute the extended P space by default.

For more information about TI-LFA, see TI-LFA FRR.

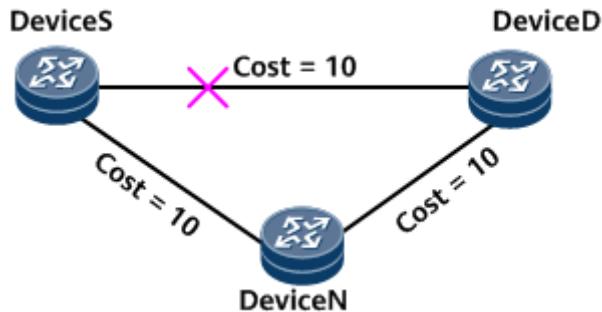

## IS-IS LFA Auto FRR

IS-IS LFA Auto FRR protects against both link and node-and-link failures.

- Link protection: Link protection applies to traffic transmitted over specified links.

In the example network shown in [Figure 1-245](#), traffic flows from DeviceS to DeviceD, and the link cost meets the preceding link protection inequality. If the primary link (DeviceS -> DeviceD) fails, DeviceS switches the traffic to the backup link (DeviceS -> DeviceN -> DeviceD), minimizing traffic loss.

[Figure 1-245](#) Networking for IS-IS LFA Auto FRR link protection

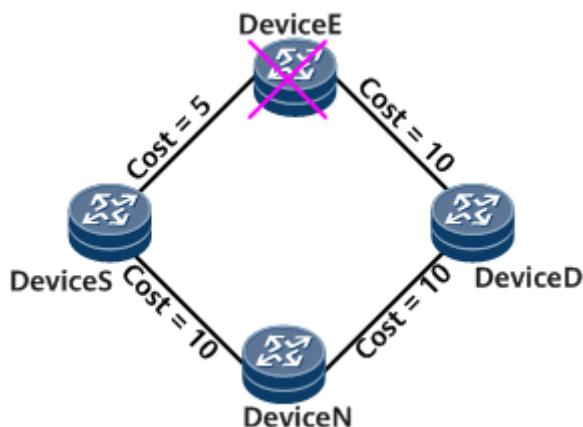

- Node-and-link protection: Node-and-link protection applies to traffic transmitted over specified nodes or links. [Figure 1-246](#) illustrates a network with node-and-link protection. Node-and-link protection takes precedence over link protection.

Node-and-link protection takes effect when the following conditions are met:

- The link cost satisfies the inequality:  $\text{Distance}_{\text{opt}}(N, D) < \text{Distance}_{\text{opt}}(N, S) + \text{Distance}_{\text{opt}}(S, D)$ .
- The interface cost of the device satisfies the inequality:  $\text{Distance}_{\text{opt}}(N, D) < \text{Distance}_{\text{opt}}(N, E) + \text{Distance}_{\text{opt}}(E, D)$ .

S indicates the source node of traffic, E indicates the faulty node, N indicates the node on the backup link, and D indicates the destination node of traffic.

[Figure 1-246](#) Networking for IS-IS LFA Auto FRR node-and-link protection

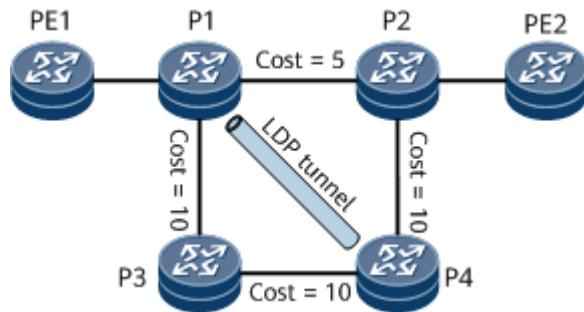

## IS-IS Remote LFA Auto FRR

Similar to IS-IS LFA Auto FRR, Remote LFA is also classified as link protection or node-and-link protection. The following example shows how Remote LFA works to protect against link failures:

In [Figure 1-247](#), traffic flows through PE1 -> P1 -> P2 -> PE2. To prevent traffic loss caused by a link fault between P1 and P2, Remote LFA calculates a PQ node (P4) and establishes an LDP tunnel between P1 and P4. If P1 detects a failure on the link between P1 and P2, P1 encapsulates packets into MPLS packets and forwards the MPLS packets to P4. After receiving the packets, P4 removes the MPLS label from them, searches its IP routing table for a next hop, and forwards the packets to the next hop. Finally, the packets reach their destination (PE2). This implements fast path switching and avoids traffic loss.

**Figure 1-247** Networking for Remote LFA

On the network shown in [Figure 1-247](#), PQ nodes are calculated as follows:

1. SPTs are calculated, with each of P1's neighbors (excluding the neighbors on the primary link) as the root. In this case, the neighbors PE1 and P3 are used as roots. For each SPT, an extended P space is composed of the root node and those nodes reachable through non-P1-P2 links. When PE1 is used as a root node for calculation, the extended P space {PE1, P1, P3} is obtained. When P3 is used as a root node for calculation, the extended P space {PE1, P1, P3, P4} is obtained. By combining these two extended P spaces, the final extended P space {PE1, P1, P3, P4} is obtained.
2. A reverse SPT with PE2 as the root is calculated. The Q space is {P2, PE2, P4}.
3. The node that exists both in the extended P space and Q space is the PQ node. In this example, P4 is the PQ node.

### NOTE

IPv6 IS-IS Remote LFA Auto FRR protects IPv6 traffic and uses IPv4 LDP LSPs. The principle of IPv6 IS-IS Remote LFA Auto FRR is similar to that of IPv4 IS-IS Remote LFA Auto FRR.

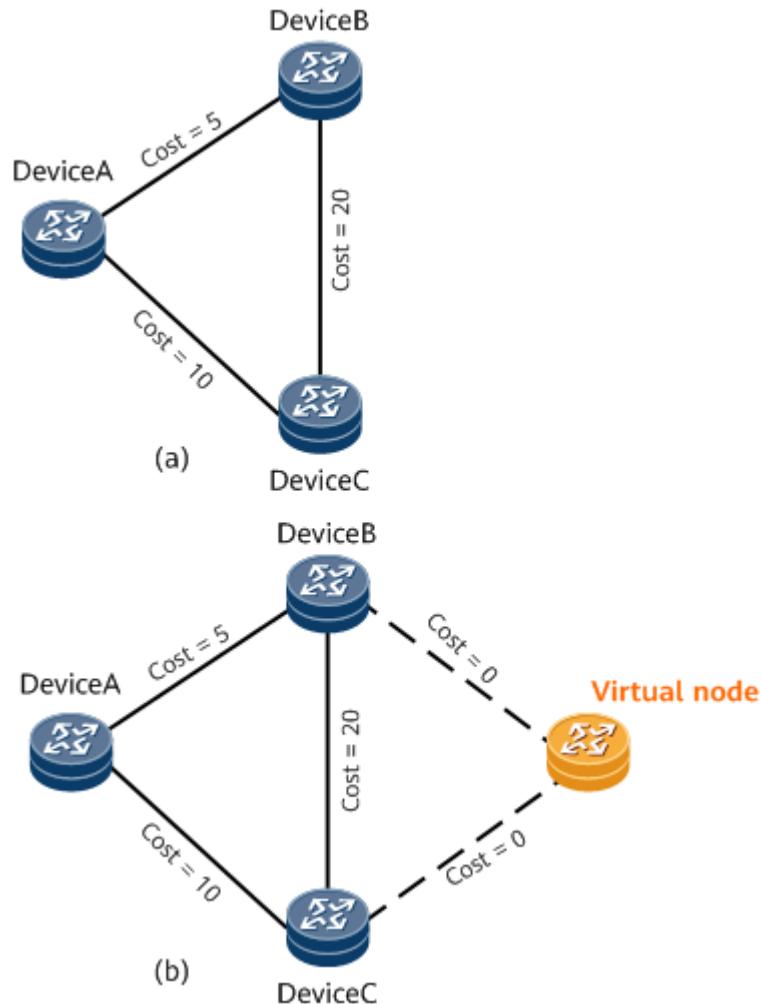

On a network with a large number of nodes, to ensure that RLFA/TI-LFA calculation can be completed as soon as possible, the elected P and Q nodes may not be optimal, but they comply with rules. This does not affect the protection effect.

## IS-IS FRR in the Scenario Where Multiple Nodes Advertise the Same Route

IS-IS LFA FRR uses the SPF algorithm to calculate the shortest path to the destination node, with each neighbor that provides a backup link as the root node.

The backup next hop is node-based, which applies to single-node routing scenarios, that is, scenarios where a route is received from only one node. With the diversification of networks, multi-node routing scenarios appear, where multiple nodes advertise the same route. Such scenarios do not meet single-node LFA conditions. As a result, the backup next hop cannot be calculated. IS-IS FRR for multi-node routing scenarios can address this problem by using a routing source to protect the primary routing source and improve network reliability.

**Figure 1-248** IS-IS FRR in the scenario where multiple nodes advertise the same route

In **Figure 1-248(a)**, the cost of the link between Device A and Device B is 5, whereas the cost of the link between Device A and Device C is 10. Both Device B and Device C advertise the route 10.1.1.0/24. IS-IS FRR is enabled on Device A. However, Device A cannot calculate the backup next hop of the route 10.1.1.0/24 because the LFA conditions in the scenario where each route is received from a single node cannot be met. To address this issue, IS-IS FRR for the scenario where multiple nodes advertise the same route can be used.

In **Figure 1-248(b)**, a virtual node is simulated between Device B and Device C and is connected to Device B and Device C. The cost of the link from Device B or Device C to the virtual node is 0, whereas the cost of the link from the virtual

node to Device B or Device C is the maximum value. After the virtual node advertises the route 10.1.1.0/24, Device A can use the LFA algorithm to calculate the backup next hop of the virtual node because the scenario where multiple nodes advertise the same route has been converted to the scenario where the route is received from only one node. Then the route 10.1.1.0/24 inherits the backup next hop from the virtual node. In this example, the primary link to the virtual node is the one from Device A to Device B, and the backup link is the one from Device A to Device C.

## IS-IS ECMP FRR

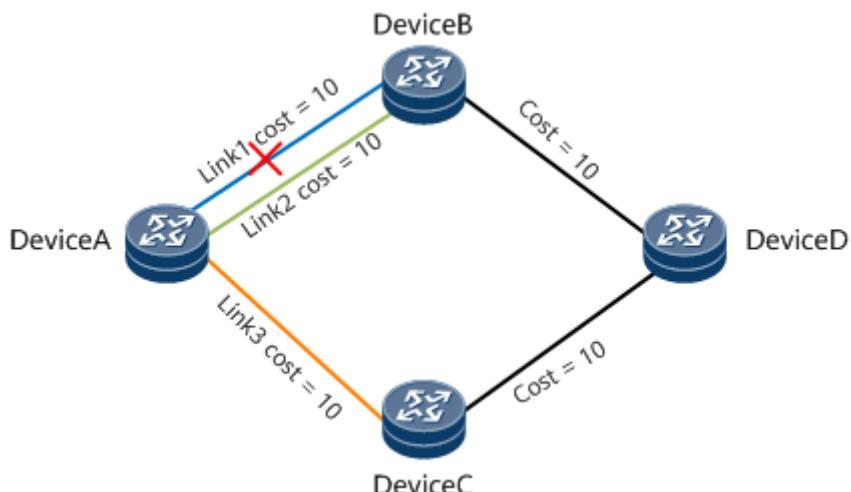

Equal cost multi path (ECMP) evenly balances traffic over multiple equal-cost paths to the same destination.

If the ECMP FRR function is not supported in ECMP scenarios, no backup next hop can be calculated for primary links.

IS-IS ECMP FRR is enabled by default, and a backup next hop is calculated separately for each primary link, which enhances reliability in ECMP scenarios. With ECMP FRR, IS-IS pre-calculates backup paths for load balancing links based on the LSDBs on the entire network. The backup paths are stored in the forwarding table and are used for traffic protection in the case of link failures.

- In **Figure 1-249**, traffic is forwarded from Device A to Device D and is balanced among Link 1, Link 2, and Link 3. Backup paths of the three links are calculated based on ECMP FRR. For example, the backup paths of Link 1, Link 2, and Link 3 are Link 3, Link 3, and Link 2, respectively.
  - If the ECMP FRR function is not enabled in the load balancing scenario and Link 1 fails, traffic over Link 1 is randomly switched to Link 2 or Link 3, which affects service traffic management.
  - If the ECMP FRR function is enabled in the load balancing scenario and Link 1 fails, traffic over Link 1 is switched to Link 3 according to FRR route selection rules, which enhances service traffic management.

**Figure 1-249** Flexible selection of backup paths through IS-IS ECMP FRR

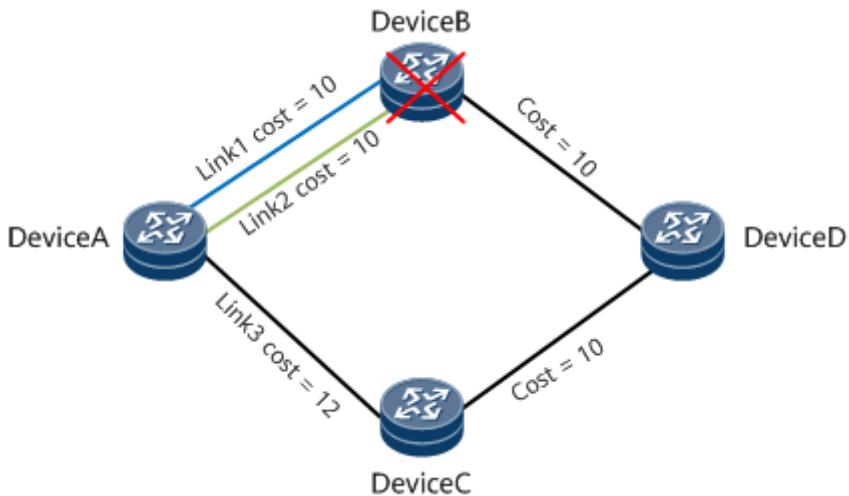

- In **Figure 1-250**, traffic is forwarded from Device A to Device D and is balanced between Link 1 and Link 2. Backup paths of the two links are

calculated based on ECMP FRR. For example, the backup paths of Link 1 and Link 2 are both Link 3.

- If the ECMP FRR function is not enabled in the load balancing scenario and Device B fails, Link 1 and Link 2 fail accordingly, leading to a traffic interruption.
- If the ECMP FRR function is enabled in the load balancing scenario and Device B fails, Link 1 and Link 2 fail accordingly. However, traffic is switched to Link 3, which prevents the traffic interruption.

**Figure 1-250** Enhanced traffic protection through IS-IS ECMP FRR

## IS-IS SRLG FRR

A shared risk link group (SRLG) is a set of links that share a common physical resource, such as an optical fiber. These links share the same risk level. If one of the links fails, all the other links in the SRLG may also fail.

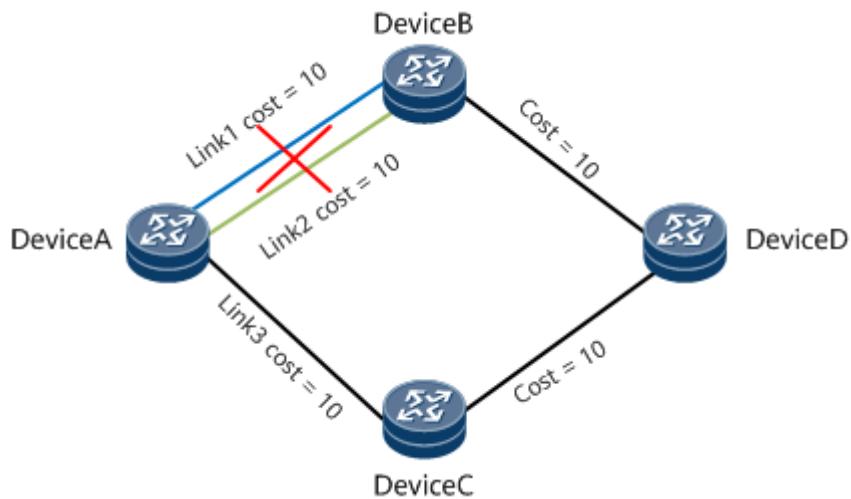

In [Figure 1-251](#), IS-IS SRLG FRR is configured, traffic between Device A and Device B is balanced by Link 1 and Link 2.

If IS-IS LFA Auto FRR is enabled, it implements protection for Link 1 and Link 2. That is, the two links back up each other.

- If Link 1 fails but Link 2 is normal, traffic is not interrupted after being switched to the backup link.
- If both Link 1 and Link 2 fail, traffic is interrupted after being switched to the backup link.

IS-IS SRLG FRR prevents service interruptions in the scenario where links have the same risk of failure. Add Link1 and Link2 to the same SRLG group so that the device preferentially selects a link in a different SRLG group when calculating a backup path, reducing the possibility of network traffic interruption.

Figure 1-251 Networking for IS-IS SRLG FRR

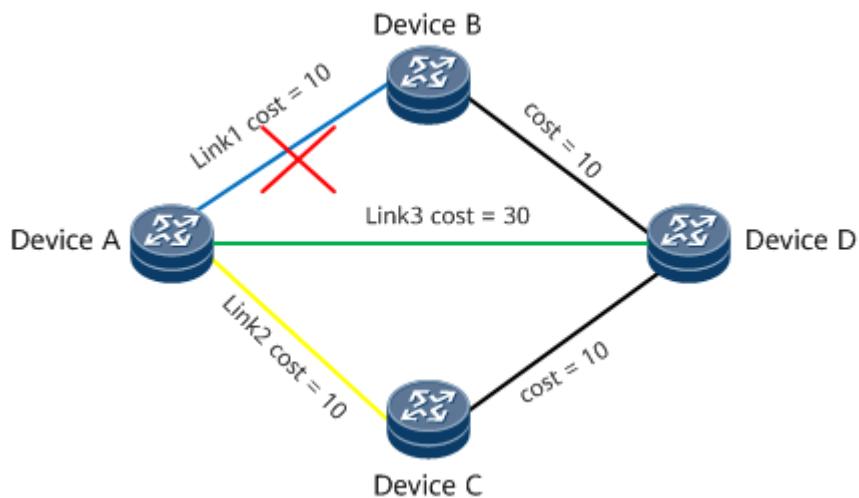

In an IS-IS remote SRLG FRR scenario shown in [Figure 1-252](#), traffic is forwarded from Device A to Device B.

In this case, Link1 is the primary path and Link2 is the backup path. If the link between Device C and Device D and Link1 are in the same SRLG:

- If Link1 fails but the link between Device C and Device D is normal, network traffic is switched to the backup path and can be forwarded normally.
- If both Link1 and the link between Device C and Device D fail, traffic is interrupted after being switched to the backup path.

If a remote link has the same risk of failure with a local link, configure IS-IS remote SRLG TI-LFA FRR so that the device preferentially selects a link that is not in an SRLG group with local links when calculating a backup path. As shown in Figure 8, Link3 is preferentially selected as the backup path, reducing the possibility of network traffic interruptions.

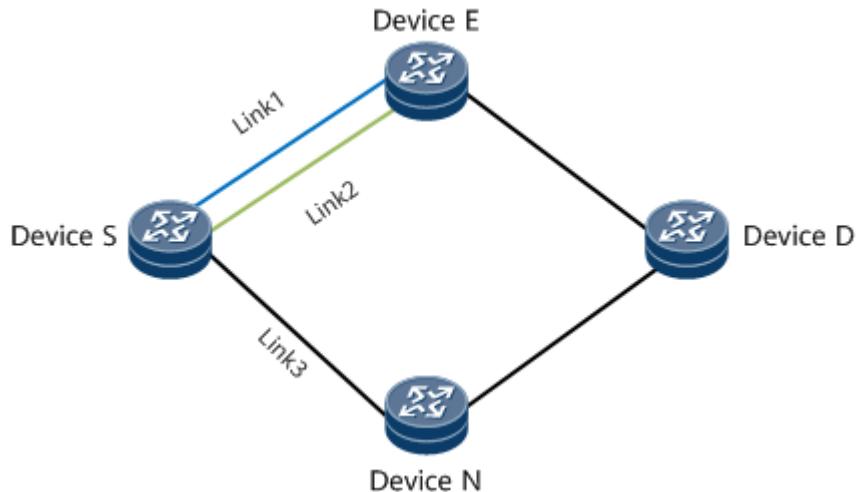

Figure 1-252 Networking diagram of IS-IS remote SRLG FRR

## Priority-based Selection of a Backup Path for IS-IS Auto FRR

When selecting a backup path for IS-IS Auto FRR, a node-protection solution is preferentially selected. However, in actual network operation, the solution of selecting a backup path for IS-IS Auto FRR may need to be changed due to factors such as interface data capabilities or link costs.

**Figure 1-253** Configuring the priority-based selection of a backup path for IS-IS Auto FRR

### Scenario 1

In [Figure 1-253](#), if the primary path is Link 1 (DeviceS -> DeviceE -> DeviceD), the backup path can be Link 2 (DeviceS -> DeviceE -> DeviceD) or Link 3 (DeviceS -> DeviceN-> DeviceD). The cost of Link 1, Link 2, and Link 3 are 10, 20, and 100, respectively. By default, Link 3 is preferentially selected as the backup path. To change the solution of selecting a backup path to smallest-cost path first, run the **tiebreaker lowest-cost preference [ level-1 | level-2 | level-1-2 ]** command. After the command is run, Link 2 is preferentially selected as the backup path.

### Scenario 2

In [Figure 1-253](#), if traffic is forwarded from Device S to Device E, it is balanced between Link 1 and Link 2 between Device S and Device E. Device S and Device N are connected through Link 3. The cost of Link 1, Link 2 and Link 3 are 10, 10, and 15 respectively. When selecting backup paths for load balancing links, Link 1 and Link 2 select each other as the backup path. To change the solution of selecting a backup path to non-load balancing path first, run the **tiebreaker non-ecmp preference [ level-1 | level-2 | level-1-2 ]** command. After the command is run, Link 3 is preferentially selected as the backup path.

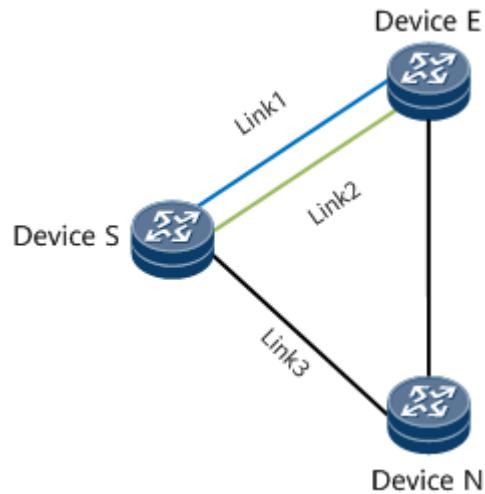

### Scenario 3

In [Figure 1-253](#), traffic is forwarded from Device A to Device D and is balanced between Link 1 and Link 2. Device S and Device N are connected through Link 3. The cost of Link 1, Link 2, and Link 3 are all 10. If IS-IS LFA Auto FRR is enabled, it implements protection for Link 1 and Link 2. That is, the two links back up each other. If Link 1 and Link 2 have the same risk of failure, you can run the

**tiebreaker srlg-disjoint preference preference [ level-1 | level-2 | level-1-2 ]** command to set the solution of selecting a backup path to SRLG-disjoint path first. In this case, the device preferentially selects Link 3 as the backup path. Before using this solution, run the **isis srlg srlg-value** command to add the links having the same risk of failure to an SRLG.

#### Scenario 4

**Figure 1-254** Selecting the link with the maximum cost as the backup path for IS-IS Auto FRR

On the network shown in [Figure 1-254](#), traffic is forwarded from Device S to Device E. The cost of Link 1 and Link 2 are 10 and 30, respectively, and the **isis peer hold-max-cost** command is run for Link 1. Device S and Device N are connected through Link 3, and Device N and Device E are directly connected. The cost of Link 3 and the link between Device N and Device E are both 10. In normal cases, the traffic from Device S to Device E is forwarded over Link 1, and the backup path is Link 3 (node protection is preferred). If Link 1 fails, the new primary path from Device S to Device E becomes Link 3, and the new backup path becomes Link 2. If Link 1 recovers after the **undo showdown** command is run, Link 1 advertises the maximum cost. In this case, to allow Link 1 to be selected as the backup path, run the **tiebreaker hold-max-cost preference preference [ level-1 | level-2 | level-1-2 ]** command.

## IS-IS Authentication

### Background

As the Internet develops, more data, voice, and video information are exchanged over the Internet. New services, such as e-commerce, online conferencing and auctions, video on demand, and distance learning, emerge gradually. The new services have high requirements for network security. Carriers need to prevent data packets from being illegally obtained or modified by attackers or unauthorized users. IS-IS authentication applies to the area or interface where packets need to be protected. Using IS-IS authentication enhances system security and helps carriers provide safe network services.

## Related Concepts

### Authentication Classification

Based on packet types, the authentication is classified as follows:

- Interface authentication: is configured in the interface view to authenticate Level-1 and Level-2 IS-to-IS Hello PDUs (IIHs).
- Area authentication: is configured in the IS-IS process view to authenticate Level-1 CSNPs, PSNPs, and LSPs.
- Routing domain authentication: is configured in the IS-IS process view to authenticate Level-2 CSNPs, PSNPs, and LSPs.

Based on the authentication modes of packets, the authentication is classified into the following types:

- Simple authentication: The authenticated party directly adds the configured password to packets for authentication. This authentication mode provides the lowest password security.
- MD5 authentication: uses the MD5 algorithm to encrypt a password before adding the password to the packet, which improves password security. For the sake of security, using the HMAC-SHA256 algorithm rather than the MD5 algorithm is recommended.
- Keychain authentication: further improves network security with a configurable key chain that changes with time.
- HMAC-SHA256 authentication: uses the HMAC-SHA256 algorithm to encrypt a password before adding the password to the packet, which improves password security.

## Implementation

IS-IS authentication encrypts IS-IS packets by adding the authentication field to packets to ensure network security. After receiving IS-IS packets from a remote router, a local router discards the packets if the authentication passwords in the packets are different from the locally configured one. This mechanism protects the local router.

IS-IS provides a type-length-value (TLV) to carry authentication information. The TLV components are as follows:

- Type: indicates the type of a packet, which is 1 byte. The value defined by ISO is 10, whereas the value defined by IP is 133.
- Length: indicates the length of the authentication TLV, which is 1 byte.
- Value: indicates the authentication information, including authentication type and authenticated password, which ranges from 1 to 254 bytes. The authentication type is 1 byte:
  - 0: reserved
  - 1: simple authentication
  - 3: general authentication, and only HMAC-SHA256 authentication currently
  - 54: MD5 authentication

- 255: private authentication

### Interface Authentication

Authentication passwords for IIHs are saved on interfaces. The interfaces send authentication packets with the authentication TLV. Interconnected router interfaces must be configured with the same password.

### Area Authentication

Every router in an IS-IS area must use the same authentication mode and have the same key chain.

### Routing Domain Authentication

Every Level-2 or Level-1-2 router in an IS-IS area must use the same authentication mode and have the same key chain.

For area authentication and routing domain authentication, you can set a router to authenticate SNPs and LSPs separately in the following ways:

- A router sends LSPs and SNPs that carry the authentication TLV and verifies the authentication information of the LSPs and SNPs it receives.
- A router sends LSPs that carry the authentication TLV and verifies the authentication information of the LSPs it receives. The router sends SNPs that carry the authentication TLV and does not verify the authentication information of the SNPs it receives.
- A router sends LSPs that carry the authentication TLV and verifies the authentication information of the LSPs it receives. The router sends SNPs without the authentication TLV and does not verify the authentication information of the SNPs it receives.
- A router sends LSPs and SNPs that carry the authentication TLV but does not verify the authentication information of the LSPs and SNPs it receives.

## IS-IS Purge Source Tracing

### Context

If network-wide IS-IS LSP deletion causes network instability, source tracing must be implemented as soon as possible to locate and isolate the fault source. However, IS-IS itself does not support source tracing. A conventional solution is to isolate nodes one by one until the fault source is located, but the process is complex and time-consuming and may compromise network services. To address this problem, enable IS-IS purge source tracing.

IS-IS purge source tracing is a Huawei proprietary protocol.

### Related Concepts

- PS-PDU: packets that carry information about the node that floods IS-IS purge LSPs.
- CAP-PDU: packets used to negotiate the IS-IS purge source tracing capability between IS-IS neighbors.
- IS-IS purge source tracing port: UDP port number used to send and receive IS-IS purge source tracing packets. This UDP port number is configurable.

## Fundamentals

IS-IS purge LSPs do not carry source information. If a device fails on the network, a large number of purge LSPs are flooded. Without a source tracing mechanism, nodes need to be isolated one by one until the faulty node is located, which is labor-intensive and time-consuming. IS-IS purge LSPs will trigger route flapping on the network, or even routes become unavailable. In this case, the device that floods the purge LSPs must be located and isolated immediately.

A solution that can meet the following requirements is required:

- 1. Information about the source that flooded the purge LSPs can be obtained when network routes are unreachable.
- 2. The method used to obtain source information must apply to all devices on the network and support incremental deployment, without compromising routing capabilities.

For requirement 1, IS-IS purge source tracing uses UDP to send and receive source tracing packets. These packets carry IS-IS LSP information purged by the faulty device and are flooded hop by hop along the IS-IS neighbor topology. After IS-IS purge source tracing packets are flooded, you can log in to any device that supports IS-IS purge source tracing to view information about the device that flooded the purge LSPs. This helps you quickly locate and isolate the faulty node.

For requirement 2, IS-IS purge source tracing forwards packets along UDP channels that are independent of the channels used to transmit IS-IS packets. In addition, source tracing does not affect the devices with the related UDP port disabled.

## Capability Negotiation

Source tracing packets are transmitted over UDP. Devices listen for the UDP port and use it to send and receive source tracing packets. If a source tracing-capable device sends source tracing packets to a device that is source tracing-incapable, the former may be incorrectly identified as an attacker. Therefore, the source tracing capability needs to be negotiated between devices so that source tracing packets are exchanged between only source tracing-capable devices. In addition, source tracing capability negotiation is also required to enable a source tracing-capable device to send source tracing information on behalf of a source tracing-incapable device.

Source tracing capability negotiation depends on IS-IS neighbor relationships. Specifically, after an IS-IS neighbor relationship is established, the local device initiates source tracing capability negotiation based on the IP address of the neighbor.

## PS-PDU Generation

If a fault source purges an LSP, it generates and floods a PS-PDU to all its source tracing neighbors.

If a device receives a purge LSP from a source tracing-incapable neighbor, the device generates and floods a PS-PDU to all its neighbors. If a device receives the same purge LSP (with the same LSP ID and sequence number) from more than one source tracing-incapable neighbor, the device generates only one PS-PDU.

PS-PDU flooding is similar to IS-IS LSP flooding.

## Security Concern

A UDP port is used to send and receive source tracing packets. Therefore, the security of the port must be taken into consideration.

The source tracing protocol inevitably increases packet receiving and sending workload and intensifies bandwidth pressure. To minimize its impact on other protocols, the number of source tracing packets must be controlled.

- Authentication

Source tracing is embedded in the IGP, inherits existing configuration parameters of the IGP, and uses authentication parameters of the IGP to authenticate packets.

- GTSM

GTSM is a security mechanism that checks whether the time to live (TTL) value in each received IP packet header is within a pre-defined range.

Source tracing packets can only be flooded as far as one hop. Therefore, GTSM can be used to check such packets by default. When a device sends a packet, it sets the TTL of the packet to 255. If the TTL is not 254 when the packet is received, the packet will be discarded.

- CPU-CAR

The NP module on interface boards can check the packets to be sent to the CPU for processing and prevent the main control board from being overloaded by a large number of packets that are sent to the CPU.

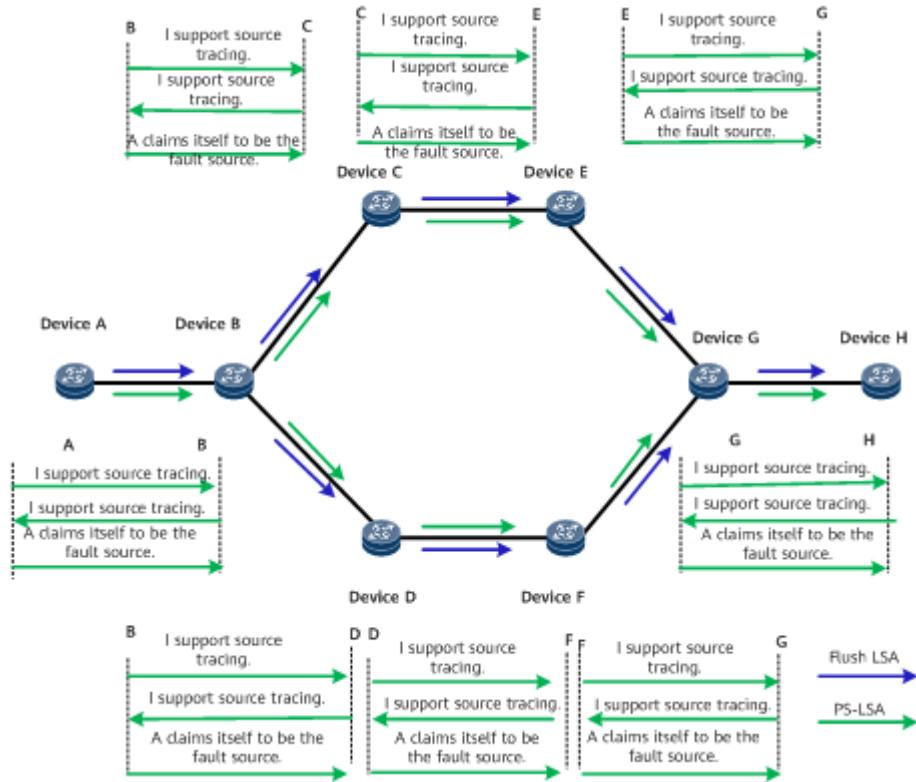

The source tracing protocol needs to apply for an independent CAR channel and has small CAR values configured.

## Typical Scenarios

### Scenario where all nodes support source tracing

Assume that all nodes on the network support source tracing and DeviceA is the fault source. In this scenario, the fault source can be accurately located. [Figure 1-255](#) shows the networking.

**Figure 1-255 Scenario where all nodes support source tracing**

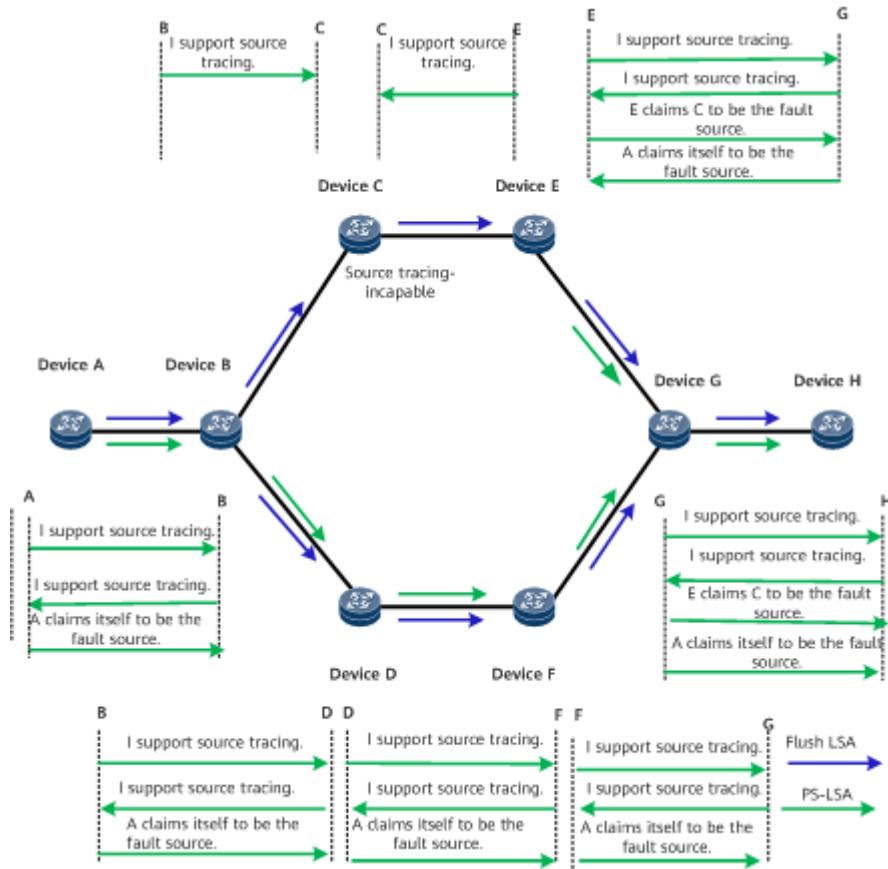

All nodes on the network support source tracing and DeviceA is the fault source.

When DeviceA purges an IGP packet, it floods a source tracing packet that carries DeviceA information and brief information about the IGP packet. Then the source tracing packet is flooded on the network hop by hop. After the fault occurs, maintenance personnel can log in to any node on the network to locate DeviceA, which keeps sending purge LSPs, and isolate DeviceA from the network.

#### Scenario where source tracing-incapable nodes are not isolated from source tracing-capable nodes

All nodes on the network except DeviceC support source tracing, and DeviceA is the faulty source. In this scenario, PS-PDUs can be flooded on the entire network, and the fault source can be accurately located. [Figure 1-256](#) shows the networking.

**Figure 1-256 Scenario where source tracing-incapable nodes are not isolated from source tracing-capable nodes**

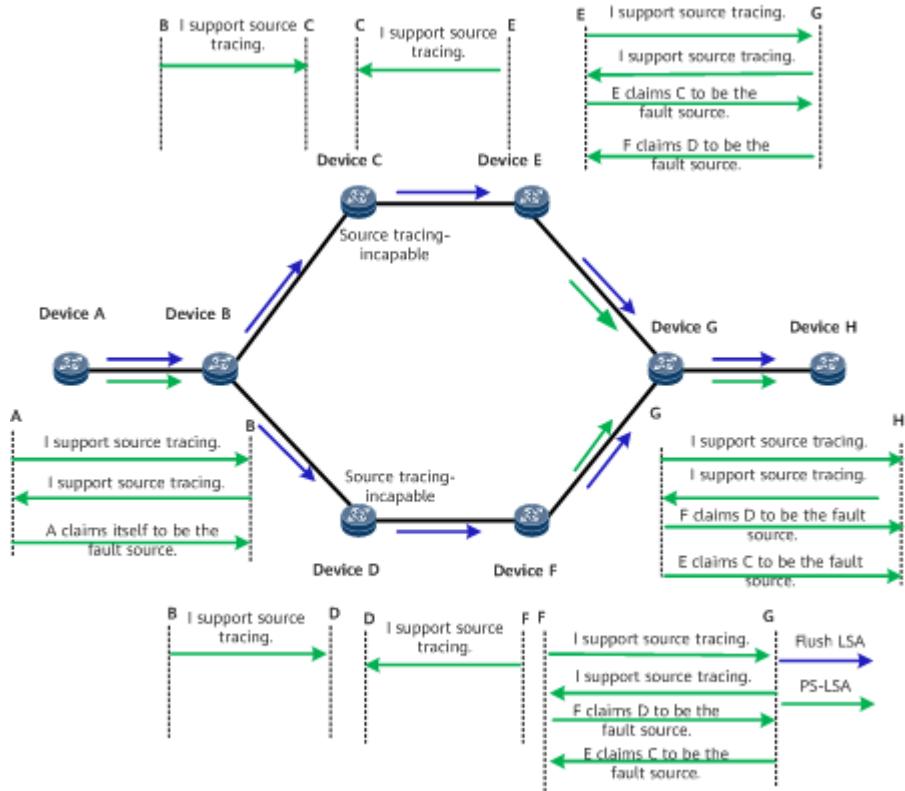

When DeviceA purges an IGP packet, it floods a source tracing packet that carries DeviceA information and brief information about the IGP packet. Then the source tracing packet is flooded on the network hop by hop. When DeviceB and DeviceE negotiate the source tracing capability with DeviceC, they find that DeviceC does not support source tracing. After DeviceB receives the PS-PDU from DeviceA, DeviceB sends the packet to DeviceD, but not to DeviceC. After receiving the purge LSP from DeviceC, DeviceE finds that DeviceC does not support source tracing and then generates a PS-PDU which carries information about the advertisement source (DeviceE), purge source (DeviceC), and the purged LSP, and floods the PS-PDU on the network.

After the fault occurs, maintenance personnel can log in to any node on the network except DeviceC to locate the faulty node. Two possible faulty nodes can be located in this case: DeviceA and DeviceC, and they both send the same purge LSP. In this case, DeviceA takes precedence over DeviceC when the maintenance personnel determine the most probable fault source. After DeviceA is isolated, the network recovers, ruling out the possibility that DeviceC is the fault source.

#### Scenario where source tracing-incapable nodes are isolated from source tracing-capable nodes

Assume that all devices except DeviceC and DeviceD support source tracing and DeviceA is the fault source. In this scenario, PS-PDUs cannot be flooded on the entire network. The fault source locating is complicated. [Figure 1-257](#) shows the networking.

**Figure 1-257 Scenario where source tracing-incapable nodes are isolated from source tracing-capable nodes**

When DeviceA purges an IS-IS LSP, it floods a PS-PDU that carries node A information and brief information about the LSP. However, the PS-PDU sent by DeviceA can only reach DeviceB because DeviceC and DeviceD do not support IS-IS purge source tracing.

During source tracing capability negotiation, DeviceE and DeviceF find that DeviceC and DeviceD do not support source tracing, respectively. After receiving the purge LSP from DeviceC, DeviceE generates and floods a PS-PDU on behalf of DeviceC. Similarly, after receiving the purge LSP from DeviceD, DeviceF generates and floods a PS-PDU on behalf of DeviceD.

After the fault occurs, maintenance personnel can locate the fault source (DeviceA) directly if they log in to DeviceA or DeviceB. After DeviceA is isolated, the network recovers. However, if the personnel log in to DeviceE, DeviceF, DeviceG, or DeviceH, they will find that DeviceE claims DeviceC to be the fault source and DeviceF claims DeviceD to be the fault source. If the personnel then log in to DeviceC or DeviceD, they will find that the purge LSP was sent by DeviceB, and was not generated by DeviceC or DeviceD. If the personnel then log in to DeviceB, they will determine that DeviceA is the fault source. After DeviceA is isolated, the network recovers.

## IS-IS MT

With IS-IS multi-topology (MT), IPv6, multicast, and advanced topologies can have their own routing tables. This feature prevents packet loss if an integrated topology and the IPv4/IPv6 dual stack are deployed, isolates multicast services

from unicast routes, improves network resource usage, and reduces network construction cost.

## Context

On a traditional IP network, IPv4 and IPv6 share the same integrated topology, and only one unicast topology exists, which causes the following problems:

- Packet loss if the IPv4/IPv6 dual stack is deployed: If some routers and links in an IPv4/IPv6 topology do not support IPv4 or IPv6, they cannot receive IPv4 or IPv6 packets sent from the router that supports the IPv4/IPv6 dual stack. As a result, these packets are discarded.
- Multicast services highly depending on unicast routes: Only one unicast forwarding table is available on the forwarding plane because only one unicast topology exists, which forces services transmitted from one router to the same destination address to share the same next hop, and various end-to-end services, such as voice and data services, to share the same physical links. As a result, some links may be heavily congested whereas others remain relatively idle. In addition, the multicast reverse path forwarding (RPF) check depends on the unicast routing table. If the default unicast routing table is used when transmitting multicast services, multicast services depend heavily on unicast routes, a multicast distribution tree cannot be planned independently of unicast routes, and unicast route changes affect multicast distribution tree establishment.

Deploying multiple topologies for different services on a physical network can address these problems. IS-IS MT transmits MT information through new TLVs in IS-IS packets. Users can deploy multiple logical topologies based on IP protocols or service types supported by links so that SPF calculations are performed independently in different topologies, which improves network usage.

### NOTE

If an IPv4 or IPv6 BFD session is Down in a topology on a network enabled with MT, neighbors of the IPv4 or IPv6 address family will be affected.

## Related Concepts

IS-IS MT allows multiple route selection subsets to be deployed on a versatile network infrastructure and divides a physical network into multiple logical topologies, where each topology performs its own SPF calculations.

IS-IS MT, an extension of IS-IS, allows multiple topologies to be applied to IS-IS. IS-IS MT complies with standard protocols and transmits multi-topology information using new TLVs in IS-IS packets. Users can deploy multiple logical topologies on a physical network. Each topology performs its own SPF calculations and maintains its own routing table. Traffic of different services, including the traffic transmitted in different IP topologies, has its own optimal forwarding path.

The MT ID configured on an interface identifies the topology bound to the interface. One or more MT IDs can be configured on a single interface.

Reverse path forwarding (RPF) check: After receiving a packet, a device searches its unicast routing table, MBGP routing table, MIGP routing table, and multicast static routing table based on the packet source and selects an optimal route from these routing tables as the RPF route. If the interface that the packet arrives at is

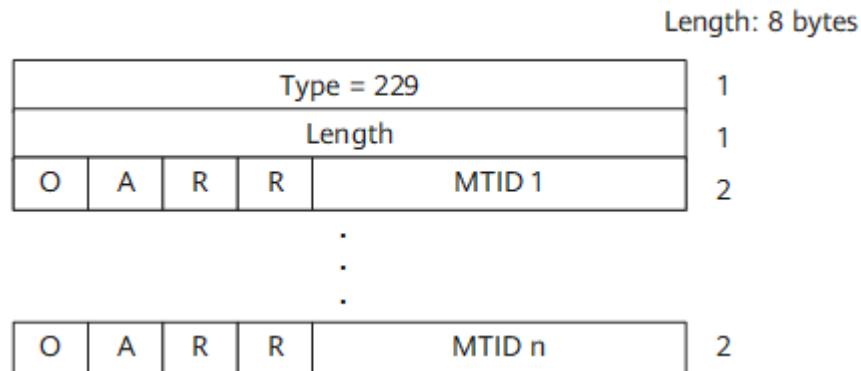

the same as the RPF interface, the packet passes the RPF check and is forwarded. Otherwise, the RPF check fails and traffic is interrupted.

## Implementation

IS-IS MT uses MT IDs to identify different topologies. Each Hello packet or LSP sent by a router carries one or more MT TLVs of the topologies to which the source interface belongs. If the router receives from a neighbor a Hello packet or LSP that carries only some of the local MT TLVs, the router assumes that the neighbor belongs to only the default IPv4 topology. On a point-to-point (P2P) link, an adjacency cannot be established between two neighbors that share no common MT ID. On broadcast links, adjacencies can still be established between neighbors even if they do not share the same MT ID.

[Figure 1-258](#) shows the MT TLV format.

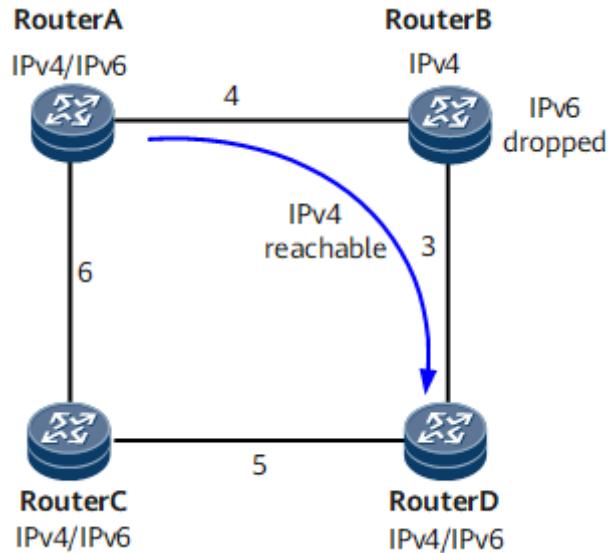

[Figure 1-258](#) MT TLV format

The following section uses IS-IS MT to describe separation of the dual stack and the separation of the multicast topology from the unicast topology.

- [Figure 1-259](#) shows the networking for separation of the IPv4 topology from the IPv6 topology. The values in the networking diagram are link costs. Device A, Device C, and Device D support the IPv4/IPv6 dual stack; Device B supports IPv4 only and cannot forward IPv6 packets.

**Figure 1-259 Separation of the IPv4 topology from the IPv6 topology**

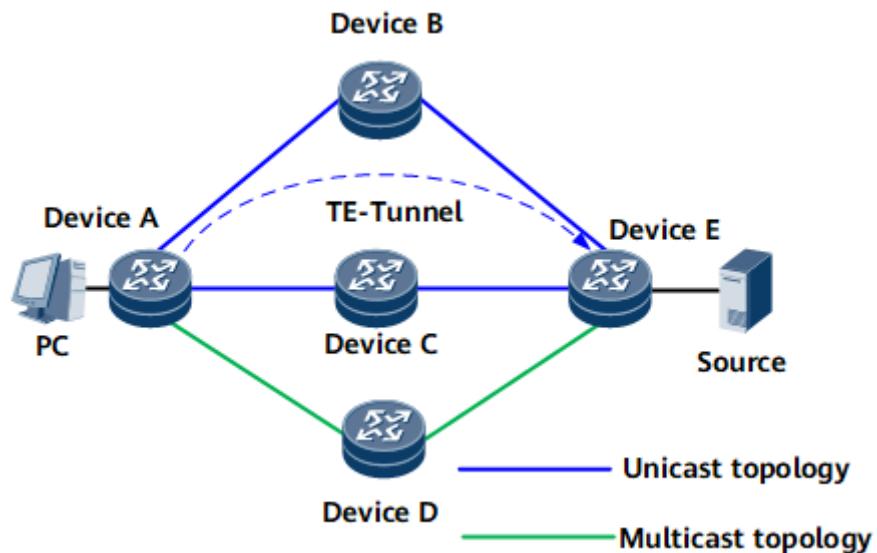

Without IS-IS MT, Device A, Device B, Device C, and Device D use the IPv4/IPv6 topology to perform SPF calculation. In this case, the shortest path from Device A to Device D is Device A -> Device B -> Device D. IPv6 packets cannot reach Device D through Device B because Device B does not support IPv6.

If a separate IPv6 topology is set up using IS-IS MT, Device A chooses only IPv6 links to forward IPv6 packets. In this case, the shortest path from Device A to Device D is Device A -> Device C -> Device D.

- **Figure 1-260** shows the networking for separation between unicast and multicast topologies using IS-IS MT.

**Figure 1-260 Separation of the multicast topology from the unicast topology**

On the network shown in [Figure 1-260](#), all routers are interconnected using IS-IS. A TE tunnel is set up between Device A (ingress) and Device E (egress). The outbound interface of the route calculated by IS-IS may not be a physical interface but a TE tunnel interface. In this case, router C through which the TE tunnel passes cannot set up multicast forwarding entries. As a result, multicast services cannot be transmitted.

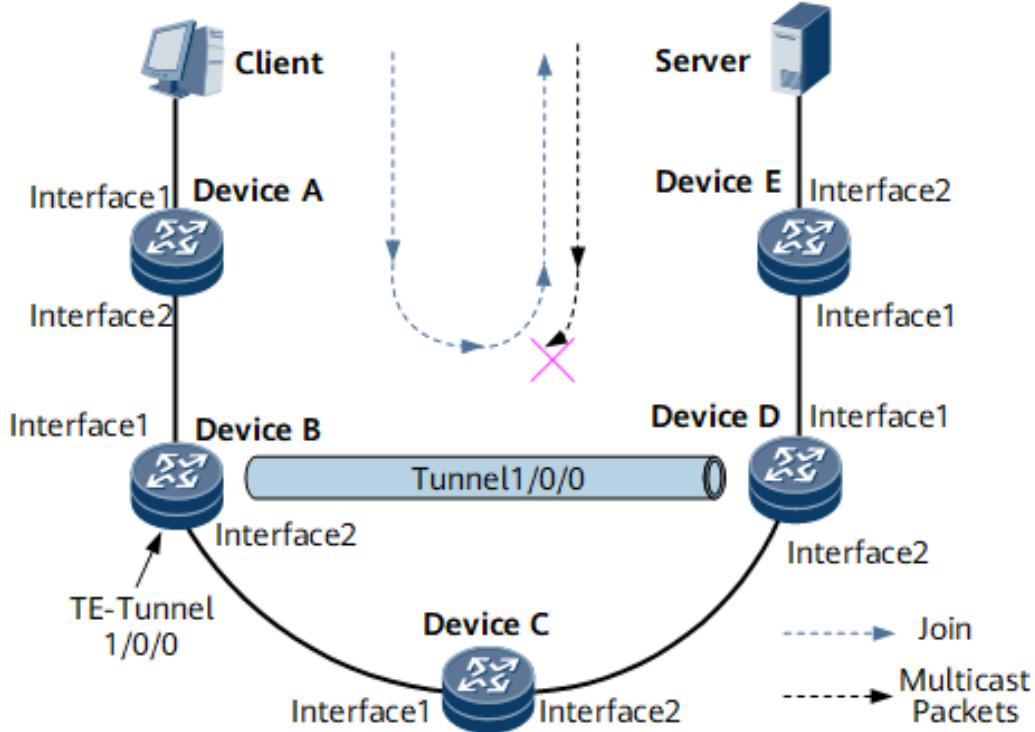

IS-IS MT addresses this problem by establishing separate unicast and multicast topologies. TE tunnels are excluded from a multicast topology. Therefore, multicast services are unaffected by TE tunnels.

## IS-IS Local MT

### Background

On a network where multicast and a unidirectional TE tunnel are deployed, if the TE tunnel is configured with IGP Shortcut, IS-IS uses an MPLS TE tunnel that is up to perform SPF calculation. In this case, the outbound interface of the route calculated by IS-IS may be a TE tunnel interface rather than a physical interface. As a result, the routers spanned by the TE tunnel cannot detect multicast packets and may discard multicast data packets, affecting network reliability. [Figure 1-261](#) shows the networking.

**Figure 1-261** Conflict between multicast and a unidirectional TE tunnel

Client and Server exchange multicast packets as follows:

1. Client sends a Report message to DeviceA, requesting to join a multicast group. Upon receipt, DeviceA sends a Join message to DeviceB.

2. When the Join message reaches DeviceB, DeviceB selects TE-Tunnel1/0/0 as the Reverse Path Forwarding (RPF) interface and forwards the message to DeviceC through Interface 2 based on an MPLS label.
3. Because the Join message is forwarded based on an MPLS label, DeviceC does not create a multicast forwarding entry. As the penultimate hop of the MPLS forwarding, DeviceC removes the MPLS label and forwards the Join message to DeviceD through Interface2.
4. After DeviceD receives the Join message, it generates a multicast forwarding entry in which the upstream and downstream interfaces are Interface1 and Interface2, respectively. DeviceD then sends the Join message to DeviceE. Then the shortest path tree is established.
5. When DeviceD receives traffic from the multicast source, DeviceD sends traffic to DeviceC. Because DeviceC has not created a forwarding entry for the traffic, the traffic is discarded. As a result, multicast services are interrupted.

IS-IS local multicast topology (MT) can address this problem.

## Related Concepts

IS-IS local MT is a mechanism that enables the routing management (RM) module to create a separate multicast topology on the local device so that protocol packets exchanged between devices are not erroneously discarded. When the outbound interface of the route calculated by IS-IS is an IGP Shortcut-enabled TE tunnel interface, IS-IS local MT calculates a physical outbound interface for the route. This mechanism resolves the conflict between multicast and a TE tunnel.

### NOTE

The TE tunnel described in this section is IGP Shortcut-enabled.

## Implementation

[Figure 1-262](#) shows how multicast packets are forwarded after local MT is enabled.

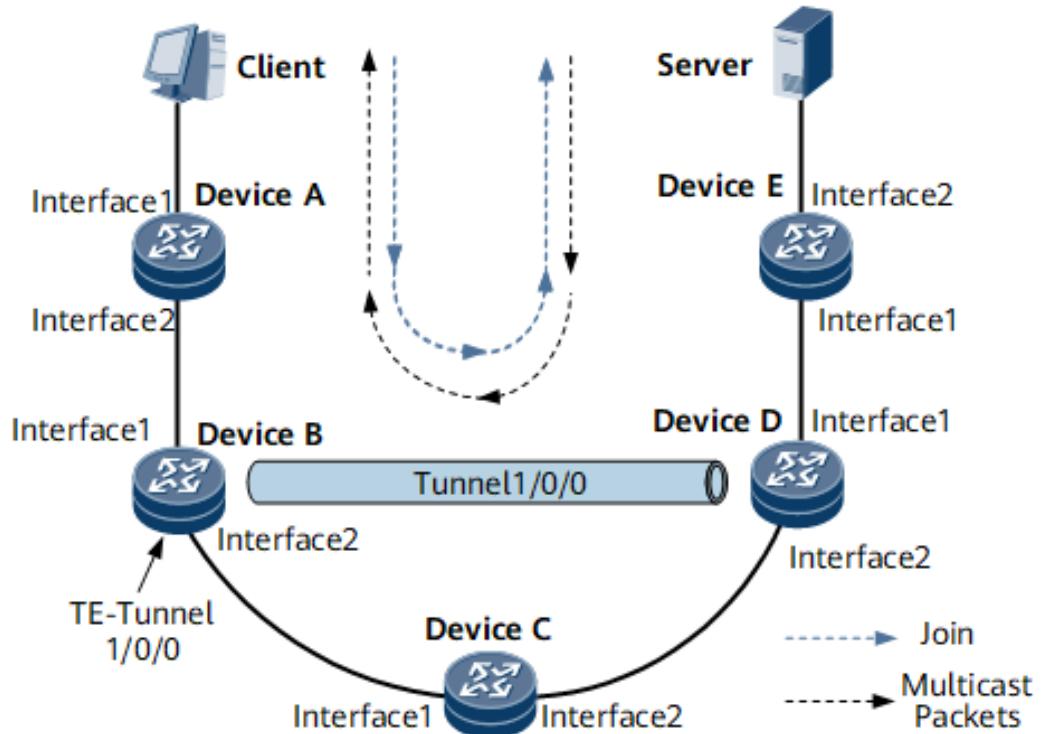

1. Establishment of a multicast IGP (MIGP) routing table

As the Shortcut TE tunnel ingress, DeviceB creates an independent MIGP routing table, records the physical interface corresponding to the TE tunnel interface, and generates multicast routing entries for multicast packet forwarding. If the outbound interface of a calculated route is a TE tunnel interface, IS-IS calculates a physical outbound interface for the route and adds the route to the MIGP routing table.

2. Multicast packet forwarding

When forwarding multicast packets, a router searches the unicast routing table for a route. If the next hop of the route is a tunnel interface, the router searches the MIGP routing table for the physical outbound interface to forward multicast packets. In this example, the original outbound interface of the route is TE tunnel 1/0/0. IS-IS re-calculates a physical outbound interface (Interface2) for the route and adds the route to the MIGP routing table. Multicast services are thus not affected by the TE tunnel. Multicast packets are forwarded through the physical outbound interfaces according to the MIGP routing table. The corresponding routing entries are created in the multicast routing table. Multicast data packets are then correctly forwarded.

Figure 1-262 Local MT networking

## Usage Scenario

IS-IS local MT prevents multicast services from being interrupted on networks, which allows multicasting and has an IGP Shortcut-enabled TE tunnel.

## Benefits

Local MT resolves the conflict between multicast and a TE tunnel and improves multicast service reliability.

## IS-IS Control Messages

IS-IS routers implement routing by exchanging control messages. This section describes IS-IS control messages.

## IS-IS PDU Formats

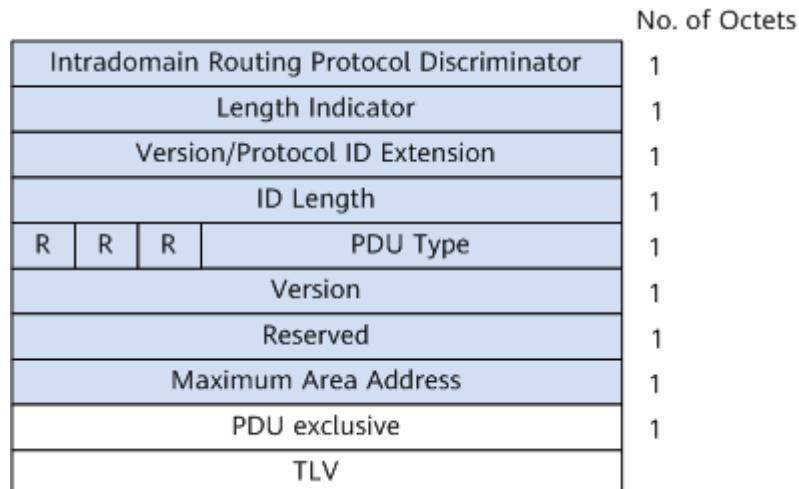

Nine types of IS-IS protocol data units (PDUs) are available for processing control information. Each PDU is identified by a 5-digit type code. IS-IS has three major types of PDUs: Hello PDUs, Link State PDUs (LSPs), and Sequence Number PDUs (SNPs). [Table 1-88](#) shows the mapping between PDUs and type values.

**Table 1-88** Mapping between PDUs and type values

| PDU Type                              | Acronym    | Type Value |
|---------------------------------------|------------|------------|
| Level-1 LAN IS-IS Hello PDU           | L1 LAN IIH | 15         |
| Level-2 LAN IS-IS Hello PDU           | L2 LAN IIH | 16         |
| Point-to-Point IS-IS Hello PDU        | P2P IIH    | 17         |
| Level-1 Link State PDU                | L1 LSP     | 18         |
| Level-2 Link State PDU                | L2 LSP     | 20         |
| Level-1 Complete Sequence Numbers PDU | L1 CSNP    | 24         |
| Level-2 Complete Sequence Numbers PDU | L2 CSNP    | 25         |
| Level-1 Partial Sequence Numbers PDU  | L1 PSNP    | 26         |
| Level-2 Partial Sequence Numbers PDU  | L2 PSNP    | 27         |

The first eight bytes in all IS-IS PDUs are public. [Figure 1-263](#) shows the IS-IS PDU format.

**Figure 1-263** IS-IS PDU format

The main fields are as follows:

- Intradomain Routing Protocol Discriminator: network layer protocol identifier assigned to IS-IS, which is 0x83.
- Length Indicator: length of the fixed header, in bytes.
- ID Length: length of the system ID of network service access point (NSAP) addresses or NETs in this routing domain.
- PDU Type: type of a PDU. For details, see [Table 1-88](#).

- Maximum Area Address: maximum number of area addresses supported by an IS-IS area. The value **0** indicates that a maximum of three area addresses are supported by this IS-IS area.
- Type/Length/Value (TLV): encoding type that features high efficiency and expansibility. Each type of PDU contains a different TLV. **Table 1-89** shows the mapping between TLV codes and PDU types.

**Table 1-89** Mapping between TLV codes and PDU types

| TLV Code | TLV Code Name                             | PDU Type          |
|----------|-------------------------------------------|-------------------|
| 1        | Area Addresses                            | I IH, LSP         |
| 2        | IS Neighbors (LSP)                        | LSP               |
| 4        | Partition Designated Level2 IS            | L2 LSP            |
| 6        | IS Neighbors (MAC Address)                | LAN I IH          |
| 7        | IS Neighbors (SNPA Address)               | LAN I IH          |
| 8        | Padding                                   | I IH              |
| 9        | LSP Entries                               | SNP               |
| 10       | Authentication Information                | I IH, LSP, or SNP |
| 128      | IP Internal Reachability Information      | LSP               |
| 129      | Protocols Supported                       | I IH or LSP       |
| 130      | IP External Reachability Information      | L2 LSP            |
| 131      | Inter-Domain Routing Protocol Information | L2 LSP            |
| 132      | IP Interface Address                      | I IH or LSP       |

## Hello Packet Format

Hello packets, also called the IS-to-IS Hello PDUs (I I H s), are used to set up and maintain neighbor relationships. Level-1 LAN I I H s are applied to the Level-1 routers on broadcast LANs. Level-2 LAN I I H s are applied to the Level-2 routers on broadcast LANs. P2P I I H s are applied to non-broadcast networks. I I H s in different networks have different formats.

- LAN I I H s: **Figure 1-264** shows the format of I I H s on a broadcast network.

**Figure 1-264** Level-1/Level-2 LAN IIH format

**Figure 1-265** P2P IIH format

|                                             | No. of Octets |
|---------------------------------------------|---------------|
| Intra-domain Routing Protocol Discriminator | 1             |
| Length Indicator                            | 1             |
| Version/Protocol ID Extension               | 1             |
| ID Length                                   | 1             |
| R R R PDU Type                              | 1             |
| Version                                     | 1             |
| Reserved                                    | 1             |
| Maximum Area Address                        | 1             |
| Reserved/Circuit Type                       | 1             |
| Source ID                                   | ID Length     |
| Holding Time                                | 2             |
| PDU Length                                  | 2             |
| Local Circuit ID                            | 1             |
| Variable Length Fields                      |               |

As shown in [Figure 1-265](#), most fields in a P2P IIH are the same as those in a LAN IIH. The P2P IIH does not have the priority and LAN ID fields but has a local circuit ID field. The local circuit ID indicates the local link ID.

## LSP Format

LSPs are used to exchange link-state information. There are two types of LSPs: Level-1 and Level-2. Level-1 IS-IS transmits Level-1 LSPs. Level-2 IS-IS transmits Level-2 LSPs. Level-1-2 IS-IS can transmit both Level-1 and Level-2 LSPs.

Level-1 and Level-2 LSPs have the same format, as shown in [Figure 1-266](#).

**Figure 1-266** Level-1 or Level-2 LSP

|                                            | No. of Octets |
|--------------------------------------------|---------------|
| Intradomain Routing Protocol Discriminator | 1             |
| Length Indicator                           | 1             |
| Version/Protocol ID Extension              | 1             |
| ID Length                                  | 1             |
| R R R PDU Type                             | 1             |
| Version                                    | 1             |
| Reserved                                   | 1             |
| Maximum Area Address                       | 1             |
| PDU Length                                 | 2             |
| Remaining Lifetime                         | 2             |
| LSP ID                                     | ID Length+2   |
| Sequence Number                            | 4             |
| Checksum                                   | 2             |
| R ATT OL IS Type                           | 1             |
| Variable Length Fields                     |               |

The main fields are as follows:

- ATT: Attached bit  
ATT is generated by a Level-1-2 router to identify whether the originating router is connected to other areas. When a Level-1 router receives a Level-1 LSP with ATT as 1 from a Level-1-2 router, the Level-1 router generates a default route destined for the Level-1-2 router so that data can be transmitted to other areas.  
Although ATT is defined in both the Level-1 LSP and Level-2 LSP, it is set only in the Level-1 LSP only by the Level-1-2 router.
- OL: LSDB overload  
LSPs with the overload bit are still flooded on networks, but the LSPs are not used when routes that pass through a device configured with the overload bit are calculated. That is, after a device is configured with the overload bit, other

devices ignore the device when performing the SPF calculation except for the direct routes of the device.

- IS Type: type of the IS-IS generating the LSP

IS Type is used to specify whether the IS-IS type is Level-1 or Level-2 IS-IS. The value **01** indicates Level-1; the value **11** indicates Level-2.

## SNP Format

SNPs describe the LSPs in all or some of the databases and are used to synchronize and maintain all LSDBs. SNPs consist of complete SNPs (CSNPs) and partial SNPs (PSNPs).

- CSNPs carry summaries of all LSPs in LSDBs, which ensures LSDB synchronization between neighboring routers. On a broadcast network, the designated intermediate system (DIS) sends CSNPs at an interval. The default interval is 10 seconds. On a P2P link, neighboring devices send CSNPs only when a neighbor relationship is established for the first time.

[Figure 1-267](#) shows the CSNP format.

[Figure 1-267](#) Level-1/Level-2 CSNP format

|                                             | No. of Octets |
|---------------------------------------------|---------------|
| Intra-domain Routing Protocol Discriminator | 1             |
| Length Indicator                            | 1             |
| Version/Protocol ID Extension               | 1             |
| ID Length                                   | 1             |
| R    R    R    PDU Type                     | 1             |
| Version                                     | 1             |
| Reserved                                    | 1             |
| Maximum Area Address                        | 1             |
| PDU Length                                  | 2             |
| Source ID                                   | ID Length+1   |
| Start LSP ID                                | ID Length+2   |
| End LSP ID                                  | ID Length+2   |
| Variable Length Fields                      |               |

The main fields are as follows:

- Source ID: system ID of the router that sends SNPs
- Start LSP ID: ID of the first LSP in a CSNP
- End LSP ID: ID of the last LSP in a CSNP
- PSNPs list only the sequence numbers of recently received LSPs. A PSNP can acknowledge multiple LSPs at a time. If an LSDB is not updated, PSNPs are also used to request a new LSP from a neighbor.

[Figure 1-268](#) shows the PSNP format.

## IS-IS GR

### NOTE

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X can be configured as a GR helper rather than a GR restarter. This function is enabled by default and does not need to be configured additionally. GR is a method of implementing non-stop forwarding (NSF). The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X supports NSR. NSR has higher function specifications than NSF.

Graceful restart (GR) is a technology that ensures normal data forwarding and prevents key services from being affected when a routing protocol restarts.

When GR is not supported, the active/standby switchover triggered by various reasons causes short-time forwarding interruption and route flapping on the entire network. Route flapping and service interruption are unacceptable on a large-scale network, especially on a carrier network.

GR is an HA technique introduced to resolve the preceding problem. HA technologies comprise a set of comprehensive techniques, such as fault-tolerant redundancy, link protection, faulty node recovery, and traffic engineering. As a fault-tolerant redundancy technology, GR is widely used to ensure non-stop forwarding of key data during the active/standby switchover and system upgrade.

When the GR function is enabled, the forwarding plane continues data forwarding during a restart, and operations on the control plane, such as re-establishment of neighbor relationships and route calculation, do not affect the forwarding plane, preventing service interruption caused by route flapping and improving network reliability.

## Routing Loop Detection for Routes Imported to IS-IS

Routes of an IS-IS process can be imported to another IS-IS process or the process of another protocol (such as OSPF or BGP) for redistribution. However, if a device

that performs such a route import is incorrectly configured, routing loops may occur. IS-IS can use the routing loop detection function to detect routing loops.

## Related Concepts

### Redistribute ID

IS-IS uses a system ID as a redistribution identifier, OSPF and OSPFv3 use a router ID + process ID as a redistribution identifier, and BGP uses a VrfID + random number as a redistribution identifier. For ease of understanding, the redistribution identifiers of different protocols are all called Redistribute IDs. When routes are distributed, the extended TLVs carried in the routes contain Redistribute IDs.

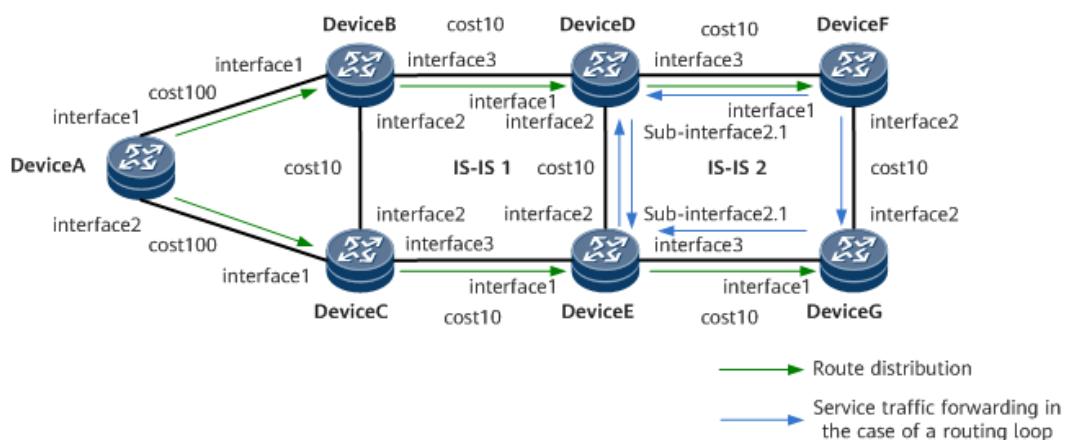

### Redistribute List

A Redistribute list may consist of multiple Redistribute IDs. Each Redistribute list of BGP contains a maximum of four Redistribute IDs, and each Redistribute list of any other routing protocol contains a maximum of two Redistribute IDs. When the number of Redistribute IDs exceeds the corresponding limit, the old ones are discarded according to the sequence in which Redistribute IDs are added.

## Cause (IS-IS Inter-Process Mutual Route Import)

On the network shown in [Figure 1-269](#), DeviceA, DeviceB, and DeviceC run IS-IS process 1, DeviceF and DeviceG run IS-IS process 2, and DeviceD and DeviceE run both processes. DeviceD and DeviceE are configured to import routes between IS-IS processes 1 and 2. The routes distributed by IS-IS process 1 are re-distributed back to IS-IS process 1 through IS-IS process 2. As the costs of the newly distributed routes are smaller, they are preferentially selected, resulting in routing loops.

**Figure 1-269** Typical network diagram of IS-IS inter-process mutual route import

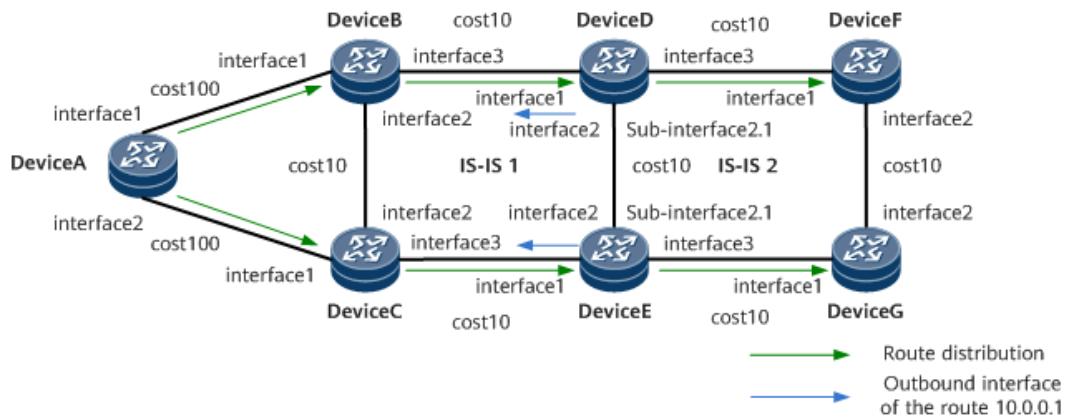

Take DeviceA distributing route 10.0.0.1/32 as an example. A stable routing loop is formed through the following process:

### Phase 1

On the network shown in [Figure 1-270](#), IS-IS process 1 on DeviceA imports the static route 10.0.0.1, generates an LSP carrying the prefix of this route and floods the LSP in IS-IS process 1. After receiving the LSP, IS-IS process 1 on DeviceD and

IS-IS process 1 on DeviceE each calculate a route to 10.0.0.1, with the outbound interface being interface1 on DeviceD and interface1 on DeviceE, respectively, and the cost being 110. At this point, the routes to 10.0.0.1 in IS-IS process 1 in the routing tables of DeviceD and DeviceE are active.

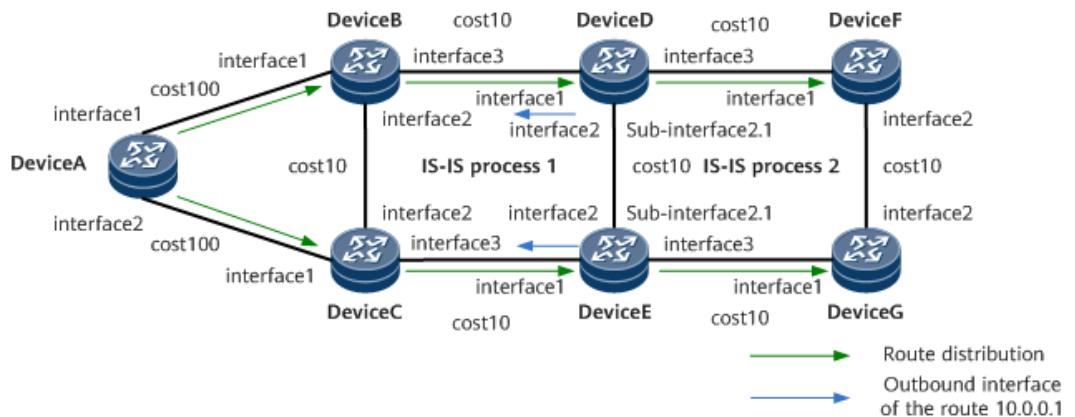

**Figure 1-270 Phase 1**

### Phase 2

In [Figure 1-271](#), DeviceD and DeviceE are configured to import routes from IS-IS process 1 to IS-IS process 2. Either no route-policy is configured for the import or the configured route-policy is improper. DeviceE is used as an example. In phase 1, the route to 10.0.0.1 in IS-IS process 1 in the routing table of DeviceE is active. In this case, IS-IS process 2 imports this route from IS-IS process 1, generates an LSP carrying the prefix of this route, and floods the LSP in IS-IS process 2. After receiving the LSP, IS-IS process 2 on DeviceD calculates a route to 10.0.0.1, with the cost being 10, which is smaller than that (110) of the route calculated by IS-IS process 1. As a result, the active route to 10.0.0.1 in the routing table of DeviceD is switched from the one calculated by IS-IS process 1 to the one calculated by IS-IS process 2, and the outbound interface is sub-interface 2.1.

**Figure 1-271 Phase 2**

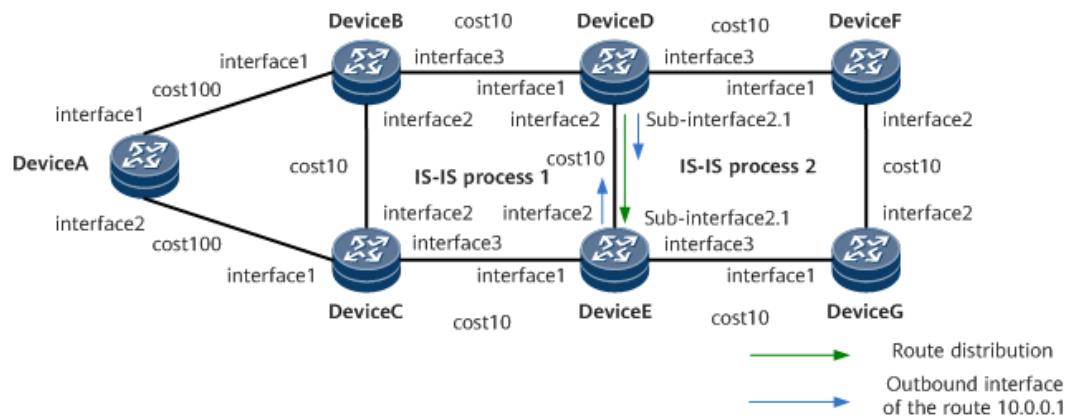

### Phase 3

In [Figure 1-272](#), after the route to 10.0.0.1 in IS-IS process 2 on DeviceD becomes active, IS-IS process 1 imports this route from IS-IS process 2, generates an LSP

carrying the prefix of this route, and floods the LSP in IS-IS process 1. After receiving the LSP, IS-IS process 1 on DeviceE recalculates the route to 10.0.0.1, with the cost being 10, which is smaller than that (110) of the previously calculated route. As a result, the route to 10.0.0.1 in IS-IS process 1 in the routing table of DeviceE is switched to the route (with the smaller cost) advertised by DeviceD, and the outbound interface is interface 2.

**Figure 1-272 Phase 3**

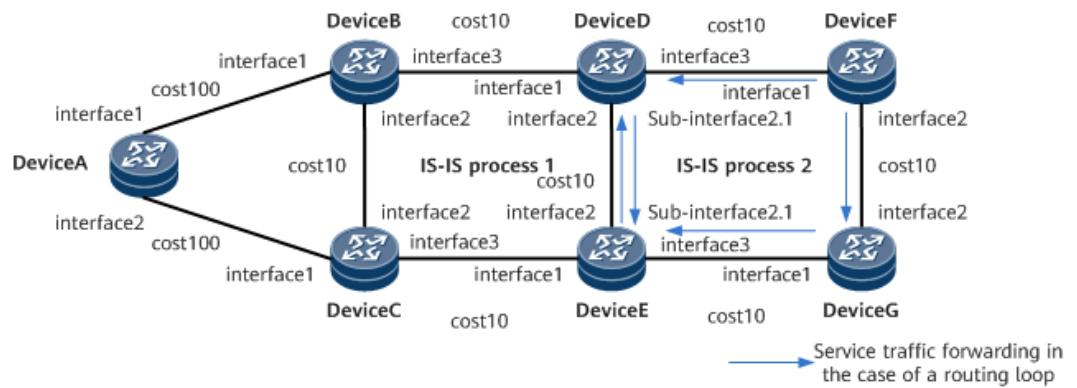

#### Phase 4

After the active route to 10.0.0.1 on DeviceE is updated, IS-IS process 2 still imports the route from IS-IS process 1 as the route remains active, and continues to advertise/update an LSP.

As a result, a stable routing loop is formed. Assuming that traffic is injected from DeviceF, [Figure 1-273](#) shows the traffic flow when the routing loop occurs.

**Figure 1-273 Traffic flow when a routing loop occurs**

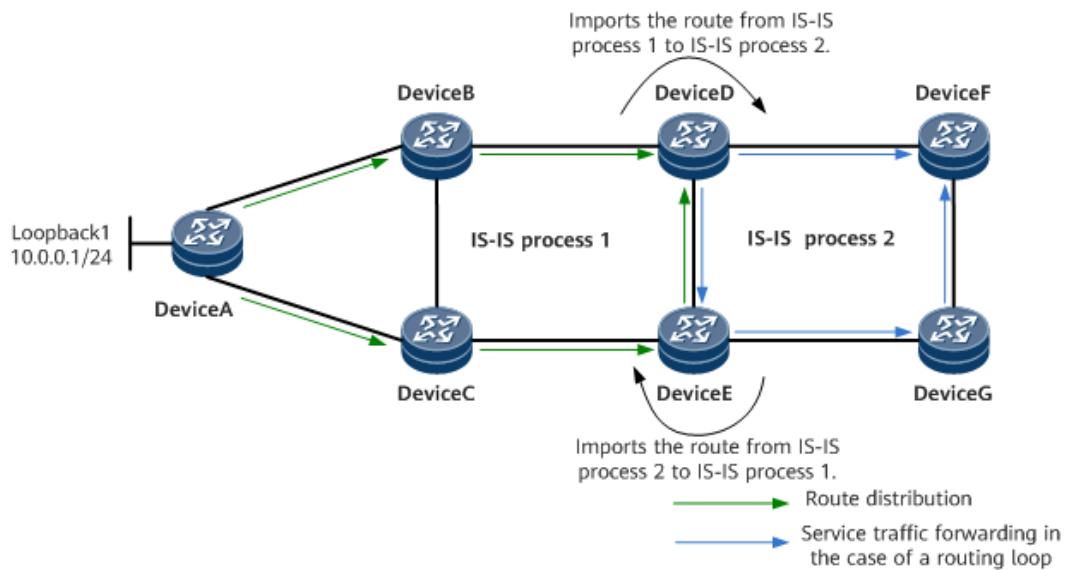

### Implementation (IS-IS Inter-Process Mutual Route Import)

Routing loop detection for IS-IS inter-process mutual route import can resolve the routing loop in the preceding scenario.

When distributing a TLV (with the type value of 135 or 235) for an imported route, IS-IS also uses a sub-TLV (with the type value of 10) of the TLV (with the type value of 135 or 235) to distribute to other devices the Redistribute ID of the device that re-distributes the imported route. If the route is re-distributed by

multiple devices, a maximum of two Redistribute IDs of these devices are distributed through the sub-TLV (with the type value of 10) of the TLV (with the type value of 135 or 235). After receiving the sub-TLV, a route calculation device saves the Redistribute IDs of the re-distribution devices along with the route. When the route is imported by another process, the device checks whether the re-distribution information of the route contains the Redistribute ID of the local process. If the information contains the Redistribute ID of the local process, the device determines that a routing loop occurs and distributes a large route cost in the TLV (with the type value of 135 or 235) for the imported route. This ensures that other devices preferentially select other paths after learning the route, preventing routing loops.

**Figure 1-274** Typical networking of route import to IS-IS

The following uses the networking shown in [Figure 1-274](#) as an example to describe how a routing loop is detected and resolved.

1. DeviceD learns the route distributed by DeviceB through IS-IS process 1 and imports the route from IS-IS process 1 to IS-IS process 2. When distributing the imported route, IS-IS process 2 on DeviceD distributes the Redistribute ID of IS-IS process 2 through the sub-TLV (with the type value of 10) of the TLV (with the type value of 135 or 235). Similarly, IS-IS process 2 on DeviceE learns the route distributed by DeviceD and saves the Redistribute ID distributed by IS-IS process 2 on DeviceD to the routing table during route calculation.
2. When re-distributing the route imported from IS-IS process 2, IS-IS process 1 on DeviceE also distributes the Redistribute ID of IS-IS process 1 on DeviceE through the sub-TLV (with the type value of 10) of the TLV (with the type value of 135 or 235).
3. After learning the route from DeviceE, IS-IS process 1 on DeviceD saves the Redistribute ID distributed by IS-IS process 1 on DeviceE in the routing table during route calculation.
4. When importing the route from IS-IS process 1 to IS-IS process 2, DeviceD finds that the re-distribution information of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an

alarm. IS-IS process 2 on DeviceD distributes a large cost when distributing the imported route so that other devices preferentially select other paths after learning the route. This prevents routing loops.

 NOTE

In the preceding typical networking:

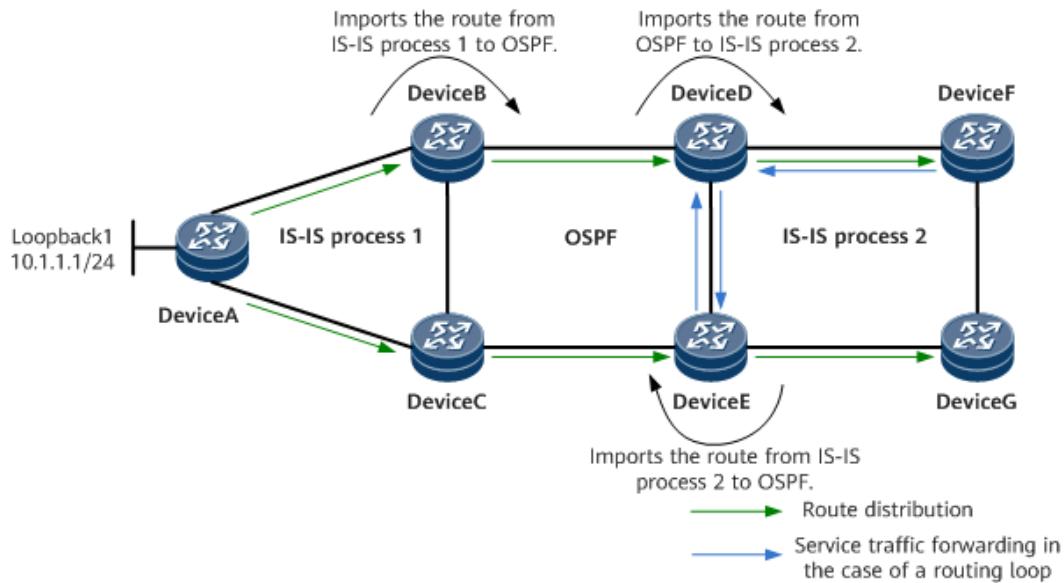

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

## Cause (Mutual Route Import Between IS-IS and OSPF)

In [Figure 1-275](#), DeviceA, DeviceB, and DeviceC run IS-IS process 1; DeviceD, DeviceE, DeviceF, and DeviceG run IS-IS process 2; in addition, DeviceB, DeviceC, DeviceD, and DeviceE run an OSPF process. DeviceB imports routes of IS-IS process 1 to OSPF, DeviceD imports OSPF routes to IS-IS process 2, and DeviceE imports routes of IS-IS process 2 to OSPF. Improper route import configurations may cause routing loops. For example, if DeviceD preferentially selects routes learned from DeviceE, a routing loop occurs between DeviceD and DeviceE. The following part describes how the routing loop is detected and resolved. Routing loop detection for routes imported to IS-IS and routing loop detection for routes imported to OSPF are enabled by default and do not need to be manually configured.

**Figure 1-275** Typical networking of route import from OSPF to IS-IS

## Implementation (Mutual Route Import Between IS-IS and OSPF)

The following uses the networking shown in [Figure 1-275](#) as an example to describe how a routing loop is detected and resolved.

1. DeviceA distributes its locally originated route 10.1.1.1/24 to DeviceB through IS-IS process 1. DeviceB imports the route from IS-IS process 1 to OSPF and adds the Redistribute ID of OSPF on DeviceB to the route when distributing the route through OSPF.
2. After learning the Redistribute list carried in the route advertised by DeviceB, OSPF on DeviceD saves the Redistribute ID of OSPF on DeviceB to the routing table during route calculation. After DeviceD imports this route from OSPF to IS-IS process 2, DeviceD redistributes the route through IS-IS process 2. In the redistributed route, the extended TLV contains the Redistribute ID of IS-IS process 2 on DeviceD and the Redistribute ID of OSPF on DeviceB. After learning the Redistribute list carried in the route advertised by DeviceD, IS-IS process 2 on DeviceE saves the Redistribute list in the routing table during route calculation.
3. After DeviceE imports this route from IS-IS process 2 to OSPF, DeviceE redistributes the route through OSPF. The redistributed route carries the Redistribute ID of OSPF on DeviceE and the Redistribute ID of IS-IS process 2 on DeviceD. The Redistribute ID of OSPF on DeviceB has been discarded from the route. DeviceD learns the Redistribute list carried in the route distributed by DeviceE and saves the Redistribute list in the routing table. When importing the OSPF route to IS-IS process 2, DeviceD finds that the Redistribute list of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. To resolve the routing loop, IS-IS process 2 on DeviceD distributes a large route cost when redistributing the route. However, because IS-IS has a higher preference than OSPF ASE, DeviceE still prefers the route learned from DeviceD through IS-IS process 2. As a result, the routing loop is not eliminated. The route received by DeviceE carries the Redistribute ID of OSPF on DeviceE and the Redistribute ID of IS-IS process 2 on DeviceD.
4. When importing the route from IS-IS process 2 to OSPF, DeviceE finds that the Redistribution information of the route contains its own Redistribute ID, considers that a routing loop is detected, and reports an alarm. To resolve the routing loop, OSPF on DeviceE distributes a large route cost when redistributing the route. In this case, DeviceD prefers the route distributed by DeviceB. As such, the routing loop is resolved.

 **NOTE**

In the preceding typical networking:

If routes are imported within a protocol on a device and the device detects a routing loop, it increases the cost of the route to be advertised. After the remote device learns this route with a large cost, it does not preferentially select this route as the optimal route in the IP routing table. In this manner, the routing loop is eliminated.

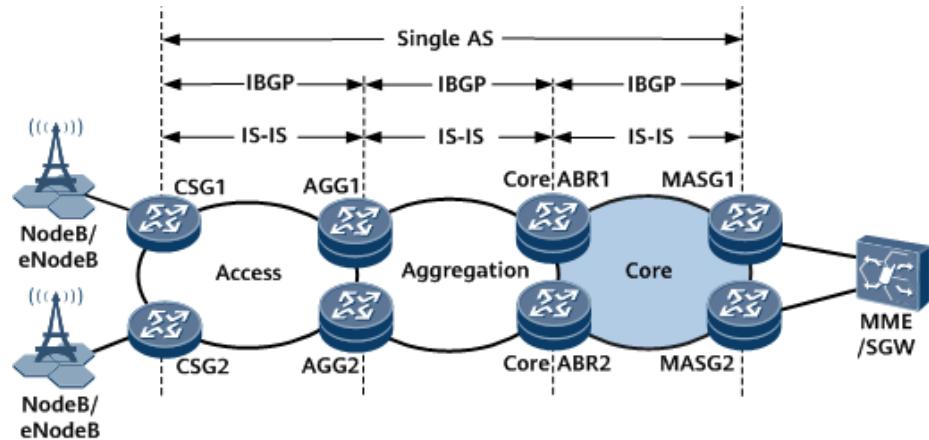

In the case of inter-protocol route import, if a routing protocol with a higher priority detects a routing loop, although this protocol increases the cost of the corresponding route, the cost increase will not render the route inactive. As a result, the routing loop cannot be eliminated. If the routing protocol with a lower priority detects a routing loop and increases the cost of the corresponding route, the originally imported route is preferentially selected. In this case, the routing loop can be eliminated.

## Application Scenarios

**Figure 1-276** shows a typical intra-AS seamless MPLS network. If the IS-IS process deployed at the access layer differs from that deployed at the aggregation layer, IS-IS inter-process mutual route import is usually configured on AGGs so that

routes can be leaked between the access and aggregation layers. As a result, a routing loop may occur between AGG1 and AGG2. If routing loop detection for IS-IS inter-process mutual route import is configured on AGG1 and AGG2, routing loops can be quickly detected and other routes can be preferentially selected, preventing routing loops.

**Figure 1-276** Routing protocol deployment for the intra-AS seamless MPLS networking

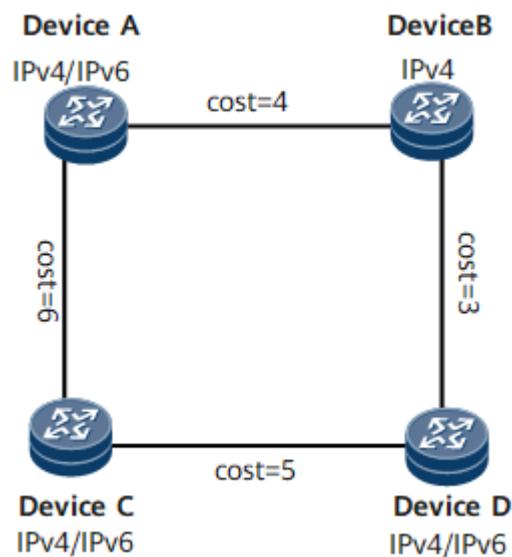

### 1.1.8.1.3 Application Scenarios for IS-IS

#### IS-IS MT

**Figure 1-277** shows the use of IS-IS MT to separate an IPv4 topology from an IPv6 topology. Device A, Device C, and Device D support IPv4/IPv6 dual-stack; Device B supports IPv4 only and cannot forward IPv6 packets.

**Figure 1-277** Separation of the IPv4 topology from the IPv6 topology

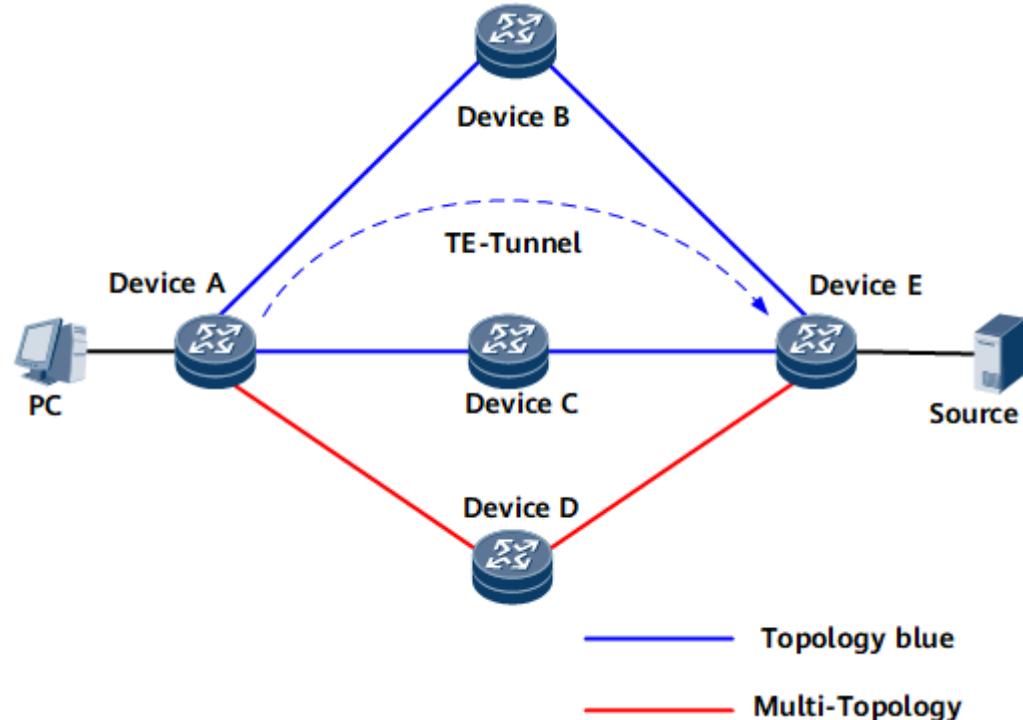

If IS-IS MT is not used, Device A, Device B, Device C, and Device D consider the IPv4 and IPv6 topologies the same when using the SPF algorithm for route calculation. The shortest path from Device A to Device D is Device A -> Device B -> Device D. Device B does not support IPv6 and cannot forward IPv6 packets to Device D.

If IS-IS MT is used to establish a separate IPv6 topology, Device A chooses only IPv6 links to forward IPv6 packets. The shortest path from Device A to Device D changes to Device A -> Device C -> Device D. IPv6 packets are then forwarded.

**Figure 1-278** shows the use of IS-IS MT to separate unicast and multicast topologies.

**Figure 1-278 Separation of the multicast topology from the unicast topology**

All routers in **Figure 1-278** are interconnected using IS-IS. A TE tunnel is set up between Device A (ingress) and Device E (egress). The outbound interface of the route calculated by IS-IS may not be a physical interface but a TE tunnel interface. The routers between which the TE tunnel is established cannot set up multicast forwarding entries. As a result, multicast services cannot run properly.

IS-IS MT is configured to solve this problem by establishing separate unicast and multicast topologies. TE tunnels are excluded from a multicast topology; therefore, multicast services can run properly, without being affected by TE tunnels.

### 1.1.8.2 IS-IS Configuration

This chapter describes the principles and provides configuration procedures and configuration examples of Intermediate System to Intermediate System (IS-IS).

### 1.1.8.2.1 Overview of IS-IS

IS-IS can be used to implement interworking on large-scale networks.

#### Definition

Intermediate System to Intermediate System (IS-IS) is a dynamic routing protocol initially designed by the International Organization for Standardization (ISO) for the Connectionless Network Protocol (CLNP).

To support IP routing, the IETF extends and modifies IS-IS in relevant standards, which enables IS-IS to be applied to both TCP/IP and Open System Interconnection (OSI) environments. The new type of IS-IS is called integrated IS-IS or dual IS-IS.

In this document, IS-IS refers to integrated IS-IS, unless otherwise stated.

#### NOTE

Unless otherwise specified, IS-IS features that support both IPv4 and IPv6 are implemented in the same way.

#### Purpose

IS-IS is an Interior Gateway Protocol (IGP) and is used within an autonomous system (AS). IS-IS is a link state protocol, and it uses the shortest path first (SPF) algorithm to calculate routes.

### 1.1.8.2.2 Configuration Precautions for IS-IS

#### Feature Requirements

**Table 1-90** Feature requirements

| Feature Requirements                                                                                                                                                                                                                                                                                                          | Series           | Models                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|--------------------------------------------------------------------------------------------|
| In IS-IS broadcast, P2P two-way handshake, IS-IS multi-instance, and IS-IS multi-topology networking scenarios, BFD session establishment check does not take effect even if the bfd session-up check command is run.<br>Association between BFD and IS-IS neighbor Up does not support broadcast interfaces or advanced MTs. | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X |
| After SR LSP strict check is configured, the SR capability of a node is strictly checked when LSPs are calculated from the current node to all nodes. If SR-LDP interworking has been deployed on the network, IS-IS SR-LDP interworking may fail, causing traffic interruptions.                                             | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X |

| Feature Requirements                                                                                                                                                                                                                                                                                                                            | Series           | Models                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|--------------------------------------------------------------------------------------------|
| After the device is restarted, if the BFD session of the local device or its neighbor is in Admin Down state, the IS-IS status is not affected. When the BFD session is renegotiated, if the BFD detection status reported by BFD is Down (used to be Up), the IS-IS neighbor is set to Down. In other cases, the IS-IS status is not affected. | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X |
| The association between BFD and IS-IS neighbor Up does not take effect on broadcast interfaces or advanced MT.                                                                                                                                                                                                                                  | NetEngine 8000 X | NetEngine 8000 X4/NetEngine 8000 X8/NetEngine 8000 X16/NetEngine 8000E X8/NetEngine 8100 X |

### 1.1.8.2.3 Configuring Basic IPv4 IS-IS Functions

This section describes how to configure basic IPv4 IS-IS functions.

#### Usage Scenario

To deploy IS-IS on an IPv4 network, configure basic IS-IS functions for communication between different nodes on the network.

Other IS-IS functions can be configured only after basic IS-IS functions are configured.

Configuring basic IPv4 IS-IS functions includes the following operations:

1. Create IPv4 IS-IS processes.
2. Configure IPv4 IS-IS interfaces.

#### Pre-configuration Tasks

Before configuring basic IPv4 IS-IS functions, complete the following tasks:

- Configure a link layer protocol.
- Assign an IP address to each interface to ensure IP connectivity.

#### Creating an IPv4 IS-IS Process

To configure basic IPv4 IS-IS functions, first create an IPv4 IS-IS process and enable IPv4 IS-IS interfaces.

#### Context

To create an IS-IS process, perform the following operations:

- **Create an IS-IS process and configure the NET of a device.**

- **(Optional) Configure the level of a device.**  
Configure the device level based on the network planning. If no device level is configured, IS-IS establishes separate neighbor relationships for Level-1 and Level-2 devices and maintains two identical LSDBs, consuming excessive system resources.
- **(Optional) Configure IS-IS host name mapping.**  
After IS-IS host name mapping is configured, a host name rather than the system ID of a device is displayed when you run a display command. This configuration improves the maintainability on an IS-IS network.
- **(Optional) Enable IS-IS adjacency strict-check.**  
If both IPv4 and IPv6 run on a network, and the IPv6 topology type of this network is **standard** or **compatible**, enable IS-IS adjacency strict-check to ensure that an IS-IS adjacency is established only when both IPv4 and IPv6 go Up. IS-IS adjacency strict-check improves network reliability and prevents traffic losses.
- **(Optional) Enable the LSDB capacity threshold alarm function.**  
An IS-IS-capable router may advertise a large number of LSPs due to an excessive number of external routes received because of incorrect configurations or attack packets. In this situation, you can configure alarm and clear alarm thresholds for the number of LSPs in the LSDB. When the proportion of the number of LSPs to the maximum number of LSPs in the LSDB exceeds the alarm threshold, an alarm is generated; when the proportion of the number of LSPs to the maximum number of LSPs in the LSDB falls below the clear alarm threshold, a clear alarm is generated.
- **(Optional) Configure IS-IS to add purge originator identification (POI) TLV to purge LSPs.**  
This function helps locate the source of error packets when a fault occurs on the network.
- **(Optional) Disable automatic IS-IS system ID recovery in case of conflicts.**  
Two devices on an IS-IS network cannot have the same system ID. Otherwise, network flapping may occur.

## Procedure

- Create an IS-IS process and configure the NET of a device.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **isis [ process-id ]**  
An IS-IS process is created, and its view is displayed.  
*process-id* specifies an IS-IS process ID. If the *process-id* parameter is not specified, the system creates process 1 by default. To associate an IS-IS process with a VPN instance, run the **isis process-id vpn-instance vpn-instance-name** command.
  - c. Run **network-entity net-addr**  
A NET is configured.  
NET of IS-IS consists of three parts:

- Area ID, which is variable (1 to 13 bytes).
- System ID (6 bytes) of this device.
- SEL, which is 1 byte and its value must be 00.

For example, the NET of IS-IS device can be configured as 10.1234.6e9f.0001.00.

#### NOTICE

- An area ID is used to uniquely identify an area in the same IS-IS domain. All routers in the same Level-1 area must share the same area ID, while routers in the same Level-2 area can have different area IDs.
- The system ID must be unique in the whole area and backbone area.
- Multiple NETs can be configured, but they must have the same system ID.

In conclusion, it is recommended that you convert the loopback interface address into a NET to ensure that the NET is unique on the network. If NETs are not unique on the network, route flapping may occur. Therefore, you need to plan the network properly. To convert the IP address of a loopback interface into a system ID, extend each decimal number of the IP address to 3 bits by adding 0s to the front of each decimal number that is shorter than 3 bits, and divide the extended IP address into three parts, with each part consisting of four digits.

d. (Optional) Run **description** *description*

A description is configured for the IS-IS process.

Configuring a description for an IS-IS process facilitates device maintenance and management. The description is not advertised through LSPs.

e. Run **commit**

The configuration is committed.

- (Optional) Configure the level of a device.
  - a. Run **is-level { level-1 | level-1-2 | level-2 }**

The level of the router is configured.
  - b. Run **commit**

The configuration is committed.
- (Optional) Configure IS-IS host name mapping.
  - a. Run **is-name** *symbolic-name*

IS-IS dynamic host name mapping is configured. The system ID of the local device is mapped to the specified host name.

This configuration is dynamic. That is, the configured *symbolic-name* is advertised to other IS-IS devices in the area through LSPs.

The configured host name (*symbolic-name*), rather than the system ID of the local device, is displayed on the IS-IS neighbors when IS-IS information is checked on these neighbors.

- b. Run **is-name map system-id symbolic-name**

IS-IS static host name mapping is configured. The system ID of a peer IS-IS device is mapped to the specified host name.

This command configuration takes effect only on the local IS-IS device. The value of *symbolic-name* will not be added to LSPs.

If dynamic host name mappings are configured on an IS-IS network, the mappings on the network override those statically configured on the local router.

- c. Run **commit**

The configuration is committed.

- (Optional) Enable IS-IS adjacency strict-check.

- a. Run **adjacency-strict-check enable**

IS-IS adjacency strict-check is enabled.

- b. Run **commit**

The configuration is committed.

- (Optional) Enable the LSDB capacity threshold alarm function.

- a. Run **lsdb limit limit-number threshold-alarm upper-limit-value lower-limit lower-limit-value**

The alarm function is enabled for the number of LSPs in the LSDB.

#### NOTE

*upper-limit-value* must be greater than or equal to *lower-limit-value*.

- b. Run **commit**

The configuration is committed.

- (Optional) Configure IS-IS to add POI TLV to purge LSPs.

- a. Run the **purge-originator-identification enable [ always ]** command to configure IS-IS to add the POI TLV (as well as the hostname TLV if the dynamic hostname function is enabled) to purge LSPs.

- If the **purge-originator-identification enable** command is run and the **send-only** parameter is specified when configuring authentication, generated purge LSPs do not carry the POI TLV or hostname TLV.

- If the **purge-originator-identification enable** command is run and HMAC-MD5 authentication is configured, generated purge LSPs do not carry the POI TLV or hostname TLV. If the command is run and authentication of another type is configured or no authentication is configured, generated purge LSPs carry the POI TLV and hostname TLV.

 NOTE

HMAC-SHA256 rather than HMAC-MD5 is recommended for the sake of security.

- If the **purge-originator-identification enable always** command is run, generated purge LSPs carry the POI TLV and hostname TLV, regardless of whether authentication is configured or whether the **send-only** parameter is specified when configuring authentication.

b. Run **commit**

The configuration is committed.

- (Optional) Disable automatic IS-IS system ID recovery in case of conflicts.

a. Run **quit**

Return to the system view.

b. Run **isis system-id auto-recover disable**

Automatic IS-IS system ID recovery is disabled in case of conflicts.

c. Run **commit**

The configuration is committed.

----End

## Configuring an IPv4 IS-IS Interface

To configure an interface on an IS-IS device to send Hello packets or flood LSPs, IS-IS must be enabled on this interface.

### Context

The level of an IS-IS device and level of an interface determine the level of a neighbor relationship. By default, Level-1 and Level-2 neighbor relationships will be established between two Level-1-2 devices. If only one level of neighbor relationships is required, you can configure the level of an interface to prevent the establishment of neighbor relationships of the other level.

After IS-IS is enabled on an interface, the interface will automatically send Hello packets, attempting to establish neighbor relationships. If a peer device is not an IS-IS device or if an interface is not expected to send Hello packets, suppress the interface. Then this interface only advertises routes of the network segment where the interface resides but does not send Hello packets. This suppression reduces the link bandwidth usage.

### Procedure

- Configure an IS-IS interface.
  - a. Run **system-view**

The system view is displayed.
  - b. (Optional) Run **isis interface limit disable**

The limit on the number of IS-IS interfaces that can be configured on the device is disabled.

After this command is run, the number of IS-IS interfaces is no longer limited to the device threshold. To restore the limit on the device, run the **undo isis interface limit disable** command. If the number of IS-IS interfaces on the device is greater than or equal to the threshold before the configuration, no more IS-IS interfaces can be added on the device.

- c. Run **interface interface-type interface-number**

The interface view is displayed.

- d. Run **isis enable [ process-id ]**

An IS-IS interface is configured.

After this command is run, the IS-IS device uses the specified interface to send Hello packets and flood LSPs.

 NOTE

No neighbor relationship needs to be established between loopback interfaces. Therefore, if this command is run on a loopback interface, the routes of the network segment where the loopback interface resides will be advertised through other IS-IS interfaces.

- e. Run **commit**

The configuration is committed.

- (Optional) Configure the level of an IS-IS interface.

- a. Run **isis circuit-level [ level-1 | level-1-2 | level-2 ]**

The level of the interface is configured.

 NOTE

Changing the level of an IS-IS interface is valid only when the level of the IS-IS device is Level-1-2. If the level of the IS-IS device is not a Level-1-2, the level of the IS-IS device determines the level of the adjacency to be established.

- b. Run **commit**

The configuration is committed.

- (Optional) Suppress an IS-IS interface.

- a. Run **isis silent [ advertise-zero-cost ]**

The IS-IS interface is suppressed.

A suppressed IS-IS interface does not send or receive IS-IS packets. The routes of the network segment where the interface resides, however, can still be advertised to other devices within the area.

- b. Run **commit**

The configuration is committed.

----End

## (Optional) Configuring Costs for IPv4 IS-IS Interfaces

Configuring the IS-IS interface costs can control IS-IS route selection.

## Context

The costs of IS-IS interfaces can be determined in the following modes (in descending order of priority):

- The interface cost takes effect only on a specified interface.
- The global cost takes effect only on all interfaces.
- The automatically calculated cost is a cost automatically calculated based on the interface bandwidth.

The default cost of an IS-IS interface is 10, and the default cost style is narrow.

## Procedure

- Configure an IS-IS cost style.

- a. Run **system-view**

The system view is displayed.

- b. Run **isis [ process-id ]**

The IS-IS view is displayed.

- c. Run **cost-style { narrow | wide | wide-compatible | { compatible | narrow-compatible } [ relax-spf-limit ] }**

An IS-IS cost style is configured.

The cost range of an interface and the cost range of routes that the interface accepts vary with the cost style.

- If the cost style is narrow, the cost of an interface ranges from 1 to 63. The maximum cost of routes that the interface accepts is 1023.
- If the cost style is narrow-compatible or compatible, the cost of an interface ranges from 1 to 63. The cost of routes that the interface accepts is related to the parameter **relax-spf-limit**.
  - If **relax-spf-limit** is not specified, the route cost is determined by the following rules:
    - If the cost of the route is not greater than 1023 and the link cost of every interface through which the route passes is less than or equal to 63, the local device accepts the actual cost of the route.
    - If the cost of the route is not greater than 1023, but the link cost of an interface through which the route passes is greater than 63, the device can learn only the routes to the network segment where the interface resides and the routes imported by the interface. The local device considers the cost of the route as the actual one and accepts the route but discards subsequent routes forwarded through the interface.
    - If the cost of the route is greater than 1023, the device can learn only the routes of the interface on which the link cost of the route exceeds 1023 for the first time. The link cost of each interface through which the route passes before the route reaches this interface is not greater than 63. The local device can learn routes to the network segment where the interface resides

- and the routes imported by the interface. The local device considers the cost of the routes as 1023 and accept them but discards subsequent routes forwarded through the interface.
- If **relax-spf-limit** is specified, the route cost is determined by the following rules:

There is no limit on link costs of interfaces or route costs. The local device considers the cost of each route as the actual one and accepts the routes.

    - If the cost style is wide-compatible or wide, the cost of the interface ranges from 1 to 16777214 or **maximum** (16777215). When the cost is **maximum**, the neighbor TLV with cost 16777215 generated on the link is used not for route calculation but for the transmission of TE information. The maximum cost of accepted routes is 0xFFFFFFFF.
- d. Run **commit**
- The configuration is committed.
- Configure a cost for the IS-IS interface.
    - a. Run **system-view**
    - b. Run **interface interface-type interface-number**
    - c. Run **isis [ topology topology-name ] cost cost [ level-1 | level-2 ]**
- A cost is configured for the IS-IS interface.
- The cost set using this command takes effect only on this interface.
- d. Run **commit**
- The configuration is committed.
- Configure the global IS-IS cost.
    - a. Run **system-view**
    - b. Run **isis [ process-id ]**
    - c. Run **circuit-cost { cost } [ level-1 | level-2 ]**
- The global IS-IS cost is configured.
- The cost set using this command takes effect on all interfaces.
- d. Run **commit**
- The configuration is committed.
- Enable IS-IS to automatically calculate interface costs.
    - a. Run **system-view**
    - b. Run **isis [ process-id ]**
- The IS-IS view is displayed.

c. Run **bandwidth-reference value**

The reference value of the bandwidth is configured.

d. Run **auto-cost enable [ compatible ]**

IS-IS is enabled to automatically calculate the interface cost.

- If the cost style of the system is wide or wide-compatible, when **auto-cost enable** command is configured, Interface cost = (Bandwidth-reference/Interface bandwidth) x 10, and when **auto-cost enable compatible** command is configured, Interface cost = (Bandwidth-reference/Interface bandwidth).

 NOTE

If the interface cost calculated through this formula is greater than 16777214, 16777214 is used as the interface cost for route calculation. That is, the interface cost will never be greater than 16777214.

The **auto-cost enable** command can be run on Eth-Trunk interfaces as same with on physical interfaces. If the command is run on an Eth-Trunk interface, the bandwidth of the Eth-Trunk interface is equal to the total bandwidth of all its member interfaces.

- If the cost-style is narrow, narrow-compatible, or compatible, the cost of each interface is determined by the interface bandwidth range. **Table 1-91** lists the interface costs corresponding to different interface bandwidth ranges.

**Table 1-91** Mapping between IS-IS interface costs and interface bandwidth

| Cost | Bandwidth Range                                    |
|------|----------------------------------------------------|
| 60   | Interface bandwidth $\leq$ 10 Mbit/s               |
| 50   | 10 Mbit/s < interface bandwidth $\leq$ 100 Mbit/s  |
| 40   | 100 Mbit/s < interface bandwidth $\leq$ 155 Mbit/s |
| 30   | 155 Mbit/s < interface bandwidth $\leq$ 622 Mbit/s |
| 20   | 622 Mbit/s < Interface bandwidth $\leq$ 2.5 Gbit/s |
| 10   | Interface bandwidth $>$ 2.5 Gbit/s                 |

 NOTE

To change the cost of a loopback interface, run the **isis cost** command only in the loopback interface view.

e. Run **commit**

The configuration is committed.

- Associate the remaining bandwidth of an IS-IS interface with the link cost.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **interface interface-type interface-number**  
The interface view is displayed.
  - c. Run **isis [ process-id process-id-value ] cost cost-value { higher-bandwidth higher-bandwidth-value cost better-cost-value | lower-bandwidth lower-bandwidth-value cost worse-cost-value } \* [ level-1 | level-2 ]**  
The remaining bandwidth of the IS-IS interface is associated with the link cost.
  - d. Run **commit**  
The configuration is committed.

----End

## (Optional) Configuring IPv4 IS-IS Attributes on Networks of Different Types

Different IS-IS attributes can be configured for different types of network interfaces.

### Context

The establishment mode of IS-IS neighbor relationships on a broadcast network is different from that on a P2P network. Different IS-IS attributes can be configured for interfaces on different types of networks.

IS-IS is required to select a DIS on a broadcast network. Configure the DIS priorities of IS-IS interfaces so that the interface with the highest priority is selected as the DIS.

The network types of the IS-IS interfaces on both ends of a link must be the same, otherwise, the IS-IS neighbor relationship cannot be established between the two interfaces. If the type of an interface on the neighbor is P2P, you can configure the interface type on the local device to P2P so that an IS-IS neighbor relationship can be established between the two devices.

IS-IS on a P2P network is not required to select a DIS. Therefore, you do not need to configure DIS priorities. To ensure the reliability of P2P links, configure IS-IS to use the three-way handshake mode for IS-IS neighbor relationship establishment so that faults on a unidirectional link can be detected.

### Procedure

- Configure the DIS priority of an IS-IS interface.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **interface interface-type interface-number**  
The interface view is displayed.

c. Run **isis dis-priority priority [ level-1 | level-2 ]**

The DIS priority is configured on the interface. The greater the value, the higher the priority.

d. (Optional) Run **isis dis-name symbolic-name**

A name is configured for the DIS to facilitate maintenance and management.

e. Run **commit**

The configuration is committed.

- Configure the network type of an IS-IS interface.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **isis circuit-type p2p**

The network type of the interface is set to P2P

When the network type of an IS-IS interface changes, interface configurations change accordingly.

- After a broadcast interface is configured as a P2P interface using the **isis circuit-type p2p** command, the default values of the interval at which Hello packets are sent, the number of Hello packets that IS-IS fails to receive from a neighbor before declaring the neighbor Down, the interval LSPs are retransmitted on a P2P link, and various IS-IS authentication modes take effect. Consequently, other configurations such as the DIS priority, DIS name, and interval at which CSNPs are sent on a broadcast network become invalid.

- After the **undo isis circuit-type** command is run to restore the network type, the default values of the interval at which Hello packets are sent, the number of Hello packets that IS-IS fails to receive from a neighbor before declaring the neighbor Down, the interval LSPs are retransmitted on a P2P link, the IS-IS authentication mode, the DIS priority, and the interval at which CSNPs are sent on a broadcast network take effect.

d. Run **commit**

The configuration is committed.

- Set the negotiation mode for the establishment of neighbor relationships over P2P links.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **isis ppp-negotiation { 2-way | 3-way [ only ] }**

A negotiation mode is specified for the interface.

This command applies only to neighbor relationship establishment over P2P links. In the case of a broadcast link, you can run the **isis circuit-type p2p** command to set the link type to P2P, and then set a negotiation mode for neighbor relationship establishment.

d. Run **commit**

The configuration is committed.

- Configure OSICP negotiation check on PPP interfaces.
  - a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **isis ppp-osicp-check**

The OSICP negotiation status is checked on a PPP interface.

This command is applicable only to PPP interfaces. For P2P interfaces, this command is invalid.

After this command is run, OSI network negotiation status of PPP affects IS-IS interface status. When PPP detects that the OSI network fails, the link status of the IS-IS interface goes down and the route to the network segment where the interface resides is not advertised through LSPs.

d. Run **commit**

The configuration is committed.

- Configure the scale of the Hello packets sent on the IS-IS interface.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

- c. Configure the size of the Hello packets to be sent by the IS-IS interface. Perform either of the following configurations as required:

- To configure the interface to send Hello packets without the padding field, run the **isis small-hello** command.
- To configure the interface to send standard Hello packets with the padding field, run the **isis padding-hello** command.

d. Run **commit**

The configuration is committed.

----End

## (Optional) Configuring IS-IS to Adjust the Flooding Rate (IPv4)

### Context

In a scenario where a large number of LSPs need to be flooded at a time, for example, in a large-scale network, because the maximum number of LSPs that can be sent by IS-IS per second is limited, the time needed to complete the LSP flooding at a time may exceed the expected time, which affects the convergence efficiency on the entire network. In this case, you can increase the maximum IS-IS LSP flooding rate by increasing the maximum number of LSPs that can be sent per second during IS-IS LSP flooding. This speeds up IS-IS LSP flooding and network convergence. When the flooding pressure on the network is heavy and flow control is required, you can reduce the maximum number of LSPs that can be sent by IS-IS per second to slow down the IS-IS LSP flooding rate and relieve the flooding pressure on nodes.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **isis lsp flood-control max-count *max-count-value***

The maximum number of LSPs that IS-IS sends every second is set.

#### Step 3 Run **commit**

The configuration is committed.

----End

## (Optional) Enabling LSP Fragment Extension on an IS-IS Device (IPv4)

If the LSP capacity is insufficient, newly imported routes and new TLVs fail to be added to LSP fragments. In this case, you can use LSP fragment extension to increase the LSP capacity, restoring the LSP space. When the LSP space is restored, the system automatically attempts to re-add these routes and TLVs to LSP fragments.

### Context

The **lsp-fragment-extend** command enables LSP fragment extension on an IS-IS device in a specified mode and at a specified level. An LSP fragment number occupies only one byte and therefore a maximum of 256 fragments are supported. If there is a large amount of LSP content and the number of fragments exceeds 256, some information is lost. LSP fragment extension can address such a problem. You can run the **virtual-system** command to configure one or more virtual systems to support more than 256 LSP fragments.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

**Step 2** Run **isis [ process-id ]**

An IS-IS process is created, and the IS-IS view is displayed.

**Step 3** Run **lsp-fragments-extend [ [ level-1 | level-2 | level-1-2 ] | [ mode-1 | mode-2 ] ] \***

LSP fragment extension is enabled on an IS-IS device, and a specified mode and level are specified.

----End

**(Optional) Enabling a Device to Encapsulate Only One Interface IP Address in IS-IS LSPs (IPv4)**

To implement interworking between Huawei and non-Huawei devices, you need to enable the type-132 TLV in LSPs to carry the IP address of only one IS-IS interface on the Huawei device.

**Context**

By default, on Huawei devices, the type-132 TLV in LSPs carries the IP addresses of all IS-IS interfaces. However, on some non-Huawei devices, the type-132 TLV in LSPs carries the IP address of only one IS-IS interface. To implement interworking between Huawei devices and these non-Huawei devices, enable the type-132 TLV in LSPs to carry the IP address of only one IS-IS interface on the Huawei devices.

**Procedure**

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** Run **isis [ process-id ]**

An IS-IS process is created, and its view is displayed.

**Step 3** Run **advertise one-interface-address**

The type-132 TLV in LSPs is enabled to carry the IP address of only one IS-IS interface.

**Step 4** Run **commit**

The configuration is committed.

----End

**Verifying the Configuration**

After configuring basic IPv4 IS-IS functions, check information about IS-IS neighbors, interfaces, and routes.

**Prerequisites**

The configurations of basic IPv4 IS-IS functions are complete.

## Procedure

- Step 1** Run the **display isis name-table** [ *process-id* | **vpn-instance** *vpn-instance-name* ] command to check the mapping between the hostname of the local device and the system ID.
- Step 2** Run the **display isis peer** [ **verbose** ] [ *process-id* | **vpn-instance** *vpn-instance-name* ] command to check information about IS-IS neighbors.
- Step 3** Run the **display isis interface** [ **verbose** ] [ *process-id* | **vpn-instance** *vpn-instance-name* ] command to check information about IS-IS interfaces.
- Step 4** Run the **display isis route** [ *process-id* | **vpn-instance** *vpn-instance-name* ] [ **ipv4** ] [ **verbose** | [ **level-1** | **level-2** ] | *ip-address* [ *mask* | *mask-length* ] ] \* command to check information about IS-IS routes.

----End

### 1.1.8.2.4 Configuring IPv4 IS-IS Route Selection

Configuring IS-IS route selection can achieve refined control over route selection.

## Usage Scenario

After basic IPv4 IS-IS functions are configured, IS-IS routes will be generated, enabling communication between different nodes on a network.

If multiple routes are available, the route discovered by IS-IS may not be the expected one, which does not meet network planning requirements nor facilitate traffic management. To address this issue, configure IPv4 IS-IS route selection to implement refined control over route selection.

To implement refined control over IPv4 IS-IS route selection, perform the following operations:

- **Configure the costs for IPv4 IS-IS interfaces.**

#### NOTE

Changing the IS-IS cost for an interface can control route selection, but routes on the interface need to be recalculated if a network topology changes, especially on a large-scale network. In addition, the configuration result may not meet your expectation.

Therefore, configure IS-IS costs before configuring basic IS-IS functions.

- Configure IPv4 IS-IS route leaking.
- Configure rules for selecting equal-cost IPv4 IS-IS routes.
- Filter IPv4 IS-IS routes.
- Configure an overload bit for an IPv4 IS-IS device.
- Configure an IPv4 IS-IS interface to automatically adjust the link cost.

## Pre-configuration Tasks

Before configuring IPv4 IS-IS route selection, complete the following tasks:

- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.

- [Configure basic IPv4 IS-IS functions.](#)

## Configuring IPv4 IS-IS Route Leaking

Configuring IS-IS route leaking enables you to optimize IS-IS route selection on a two-level-area network.

### Context

If multiple Level-1-2 devices in a Level-1 area are connected to devices in the Level-2 area, a Level-1 LSP sent by each Level-1-2 device carries an ATT flag bit of 1. This Level-1 area will have multiple routes to the Level-2 area and other Level-1 areas.

By default, routes in a Level-1 area can leak to the Level-2 area so that Level-1-2 and Level-2 devices can learn about the topology of the entire network. Devices in a Level-1 area are unaware of the entire network topology because they only maintain LSDBs in the local Level-1 area. Therefore, a device in a Level-1 area can forward traffic to a Level-2 device only through the nearest Level-1-2 device. However, the used route may not be optimal.

To enable a device in a Level-1 area to select the optimal route, configure IPv4 IS-IS route leaking so that specified routes in the Level-2 area can leak to the local Level-1 area.

If you want the Level-2 area to know only some of the routes in the local Level-1 area, configure a policy so that only desired routes can leak to the Level-2 area.

### Procedure

- Configure route leaking from the Level-2 area to the Level-1 area.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **isis [ process-id ]**  
The IS-IS view is displayed.
  - c. Configure the routes in the Level-2 area and other Level-1 areas that meet the specified conditions to leak to the local Level-1 area.  
Run any of the following commands as required:
    - Based on the basic ACL:
      - 1) Run **import-route isis level-2 into level-1 [ filter-policy { acl-number | acl-name acl-name } | tag tag | no-sid ]**  
The device is configured to leak routes into the local Level-1 area based on the specified basic ACL.
      - 2) Run **quit**  
Return to the system view.
      - 3) Run **acl { name basic-acl-name { basic | [ basic ] number basic-acl-number } | [ number ] basic-acl-number } [ match-order { config | auto } ]**  
The ACL view is displayed.

4) Run **rule [ rule-id ] [ name rule-name ] { deny | permit }**  
[ fragment-type { fragment | non-fragment | non-subseq |  
fragment-subseq | fragment-spe-first } | source { source-ip-  
address { source-wildcard | 0 | src-netmask } | any } | time-range  
time-name | vpn-instance vpn-instance-name ] \*

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:

If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.

Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.

Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

- Based on an IP prefix list:

Run **import-route isis level-2 into level-1 [ filter-policy ip-prefix ip-prefix-name | tag tag | no-sid ] \***

The device is configured to leak routes into the local Level-1 area based on the specified IP prefix list.

- Based on a route-policy:

Run **import-route isis level-2 into level-1 [ filter-policy route-policy route-policy-name | tag tag | no-sid ] \***

The device is configured to leak routes into the local Level-1 area based on the specified route-policy.

 NOTE

The command is run on the Level-1-2 device that is connected to an external area.

d. Run **commit**

The configuration is committed.

- Configure route leaking from the Level-1 area to the Level-2 area.

a. Run **system-view**

The system view is displayed.

b. Run **isis [ process-id ]**

The IS-IS view is displayed.

- Configure the routes that meet the specified conditions in the Level-1 area to leak to the Level-2 area.

Run any of the following commands as required:

■ Based on the basic ACL:

- Run **import-route isis level-1 into level-2 [ filter-policy { acl-number | acl-name acl-name } | tag tag | no-sid ]**\*

The device is configured to leak routes into the local Level-2 area based on the specified basic ACL.

- Run **quit**

Return to the system view.

- Run **acl { name basic-acl-name { basic | [ basic ] number basic-acl-number } | [ number ] basic-acl-number } [ match-order { config | auto } ]**

The ACL view is displayed.

- Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name ]**\*

The rule for the ACL is configured.

When the **rule** command is run to configure rules for a named ACL, only the source address range specified by **source** and the time period specified by **time-range** are valid as the rules.

When a filtering policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route that matches the rule will be received or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route that matches the rule will not be received or advertised by the system.
- If a route has not matched any ACL rules, the route will not be received or advertised by the system.

- If an ACL does not contain any rules, all routes matching the **route-policy** that references the ACL will not be received or advertised by the system.
- In the configuration order, the system first matches a route with a rule that has a smaller number and then matches the route with a rule with a larger number. Routes can be filtered using a blacklist or a whitelist:

Route filtering using a blacklist: Configure a rule with a smaller number and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger number in the same ACL and specify the action **permit** in this rule to receive or advertise the other routes.

Route filtering using a whitelist: Configure a rule with a smaller number and specify the action **permit** in this rule to permit the routes to be received or advertised by the system. Then, configure another rule with a larger number in the same ACL and specify the action **deny** in this rule to filter out unwanted routes.

- Based on an IP prefix list:

Run **import-route isis level-1 into level-2 [ filter-policy ip-prefix ip-prefix-name | tag tag | no-sid ] \***

The device is configured to leak routes into the local Level-2 area based on the specified IP prefix list.

- Based on a route-policy:

Run **import-route isis level-1 into level-2 [ filter-policy route-policy route-policy-name | tag tag | no-sid ] \***

The device is configured to leak routes into the local Level-2 area based on the specified route-policy.

#### NOTE

The command is run on the Level-1-2 device that is connected to an external area.

#### d. Run **commit**

The configuration is committed.

----End

## Configuring a Method for IS-IS to Process Equal-Cost Routes (IPv4)

If multiple equal-cost routes are available on an IS-IS network, you can configure load balancing to increase the bandwidth usage of each link, or configure weights for the equal-cost routes to facilitate service traffic management.

## Context

If there are multiple redundant links on an IS-IS network, multiple equal-cost routes may exist. In this case, you can use either of the following methods:

- Configure load balancing so that traffic is balanced among links.  
This method improves link utilization and reduces the possibility of congestion caused by link overload. However, load balancing randomly forwards traffic, which may affect service traffic management.
- Configure weights for equal-cost routes so that the route with the highest priority is preferentially selected, with others functioning as backups.  
In this mode, you can allow one or more routes to be preferentially selected without modifying the original configuration. This ensures network reliability and facilitates service traffic management.

## Procedure

- Configure load balancing for equal-cost IS-IS routes.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **isis [ process-id ]**  
The IS-IS view is displayed.
  - c. Run **maximum load-balancing number**  
The maximum number of equal-cost IS-IS routes for load balancing is set.

### NOTE

If the actual equal-cost routes outnumber the value specified in the **maximum load-balancing** command, routes are selected for load balancing based on the following rules:

1. Route weight: Routes with small weight values (high priority) are selected for load balancing. For details about route preference configuration, see [Configure priorities for equal-cost IS-IS routes](#).
2. Next-hop system ID: If routes have the same weight, those with small system IDs are selected for load balancing.
3. Outbound interface index: If routes have the same weight and system ID, those with small outbound interface indexes are selected for load balancing.
4. Next-hop IP address: If the weights, next-hop system IDs, and interface indexes of the routes are the same, their next-hop IP addresses are compared. The routes with high IP addresses are selected for load balancing.

- d. (Optional) Run **ecmp-prefer [ te-tunnel | intact ]**

The priority is set for the routes with a TE tunnel interface or an IPv4 interface as the outbound interface.

If both an IGP-Shortcut-enabled TE tunnel and IP link are available, you can configure a priority for the routes with a TE tunnel interface or an IPv4 interface as the outbound interface for route selection.

- e. Run **commit**  
The configuration is committed.
- Configure weights for equal-cost IS-IS routes.
  - a. Run **system-view**  
The system view is displayed.

- b. Run **isis [ process-id ]**  
The IS-IS view is displayed.
- c. Run **nexthop ip-address weight value**  
A weight is configured for an equal-cost route.

 NOTE

A smaller *value* indicates a higher priority.

- d. Run **commit**  
The configuration is committed.

----End

## Filtering IPv4 IS-IS Routes

If some IS-IS routes are not preferred, configure conditions to filter IS-IS routes. Only IS-IS routes meeting the specified conditions can be added to an IP routing table.

### Context

Only routes in an IP routing table can be used to forward IP packets. An IS-IS route can take effect only after it has been added to an IP routing table.

You can configure a basic ACL, an IP prefix list, or a route-policy to filter routes so that only the matched IS-IS routes can be delivered to the IP routing table. IS-IS routes that do not meet the specified conditions cannot be added to the IP routing table nor selected to forward IP packets.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **isis [ process-id ]**

The IS-IS view is displayed.

#### Step 3 Configure IS-IS to deliver specified IS-IS routes to the IP routing table.

Run any of the following commands as required:

- Based on the basic ACL:
  - a. Run the **filter-policy { acl-number | acl-name acl-name } import** command.
  - b. Run **quit**  
Return to the system view.
  - c. Run **acl { name basic-acl-name { basic | [ basic ] number basic-acl-number } | [ number ] basic-acl-number } [ match-order { config | auto } ]**

The ACL view is displayed.

- d. Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name ] \***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:  
If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.  
Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.  
Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.
- Based on an IP prefix list:  
Run **filter-policy ip-prefix ip-prefix-name import**
- Based on a route-policy:  
Run **filter-policy route-policy route-policy-name import**

#### Step 4 Run commit

The configuration is committed.

----End

## Configuring an Overload Bit for an IPv4 IS-IS Device

If an IS-IS device needs to be temporarily isolated, configure the overload state for it to prevent other devices from forwarding traffic to this IS-IS device and prevent routing black holes.

### Context

If an IS-IS device needs to be temporarily isolated, for upgrade or maintenance purposes for example, configure the overload state for it so that no other devices will forward traffic to this IS-IS device.

IS-IS routes converge more quickly than BGP routes do. To prevent routing black holes on a network where both IS-IS and BGP are configured, set an overload bit to instruct an IS-IS device to enter the overload state during its start or restart. After BGP convergence is complete, cancel the overload bit.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **isis [ process-id ]**

The IS-IS view is displayed.

#### Step 3 Run **set-overload { on-startup [ timeout1 | start-from-nbr system-id [ timeout1 [ timeout2 ] ] | wait-for-bgp [ timeout1 ] ] [ route-delay-distribute timeout4 ] [ send-sa-bit [ timeout3 ] ] [ route-max-metric ] } [ allow { interlevel | external } \* ]**

The overload bit is configured.

#### Step 4 Run **commit**

The configuration is committed.

----End

## Configuring IS-IS to Generate IPv4 Default Routes

This section describes how to configure IS-IS to generate default routes to control the advertising of IS-IS routing information.

### Context

The destination address and mask of a default route are all 0s. If the destination address of a packet does not match any entry in the routing table of a device, the device sends the packet along the default route. If neither the default route nor the destination address of the packet exists in the routing table, the device discards the packet and informs the source end that the destination address or network is unreachable.

IS-IS can generate default routes using either of the following mode:

- **Command-triggered default route generation mode**

You can run the **default-route-advertise** command on a device so that the device adds a default route to the LSP before sending the LSP to a neighbor. Therefore, the neighbor can learn this default route.

- **ATT bit 1-triggered default route generation mode**

According to IS-IS, a Level-1-2 router sets the ATT bit to 1 in the LSP to be advertised to a Level-1 area if the Level-1-2 router can reach more Level-1 areas through the Level-2 area than through the Level-1 area. After a Level-1 router in the Level-1 area receives the LSP, it generates a default route destined for the Level-1-2 router. Based on the network requirements, you can configure whether the Level-1-2 router sets the ATT bit carried in the LSP and whether a Level-1 router generates a default route after it receives the LSP carrying ATT bit 1.

This mode applies only to Level-1 routers.

## Procedure

- Configure command-triggered default route generation mode.
  - a. Run **system-view**

The system view is displayed.
  - b. Run **isis [ process-id ]**

The IS-IS view is displayed.
  - c. Run **default-route-advertise [ always | match default | route-policy route-policy-name | route-filter route-filter-name ] [ [ cost cost ] | [ tag tag ] | [ level-1 | level-2 | level-1-2 ] ] \* [ avoid-learning ]**

IS-IS is configured to generate default routes.

The IS-IS level of a router determines the IS-IS level of the generated default routes. The default routes generated using this command are advertised only to routers of the same level. You can configure a routing policy so that IS-IS generates default routes only when there are matched routes in the routing table.
  - d. Run **commit**

The configuration is committed.
- Configure ATT bit 1-triggered default route generation mode.
  - a. Run **system-view**

The system view is displayed.
  - b. Run **isis [ process-id ]**

The IS-IS view is displayed.
  - c. Run the following command as required:
    - To set the ATT bit in the LSPs sent by the Level-1-2 router, run the **attached-bit advertise { always | never }** command.
      - If the **always** parameter is specified, the ATT bit is set to 1. After receiving the LSPs carrying the ATT bit 1, the Level-1 router generates a default route.

- If the **never** parameter is specified, the ATT bit is set to 0. After receiving the LSPs carrying the ATT bit 0, the Level-1 router does not generate a default route, which reduces the size of a routing table.
  - To disable the Level-1 router from generating default routes even though it receives the LSPs carrying ATT bit 1, run the **attached-bit avoid-learning** command.
- d. Run **commit**

The configuration is committed.

----End

## Configuring an IPv4 IS-IS Interface to Automatically Adjust the Link Cost

Configuring an IS-IS interface to automatically adjust the link cost based on link quality facilitates route selection control and improves network reliability.

### Context

A bit error refers to the deviation between a bit that is sent and the bit that is received. The bit error rate (BER) refers to the number of bit errors divided by the total number of bits transferred during a studied time interval. During data transmission, a high BER may degrade or even interrupt services.

To prevent this problem, configure IS-IS interfaces to automatically adjust link costs based on link quality so that unreliable links are not used by the optimal routes.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **interface interface-type interface-number**

The interface view is displayed.

#### Step 3 Run **isis enable [ process-id ]**

IS-IS is enabled on the interface.

#### Step 4 Run **isis link-quality low incr-cost { cost-value | max-reachable }**

The IS-IS interface is configured to automatically adjust the link cost based on link quality.

### NOTE

The *cost* parameter specifies the link cost adjustment value. After this parameter is specified:

- If the link quality changes to **low**, the link cost equals the sum of the original link cost and the incremental cost. If the sum exceeds the maximum link cost allowed, the maximum link cost allowed is used.
  - The maximum link cost is 63, if the cost style is narrow, narrow-compatible, or compatible.
  - The maximum link cost is 16777214, if the cost style is wide or wide-compatible.
- When the link quality recovers from **low**, the link cost of the interface is restored to the original value (the one before *cost* was added).

### Step 5 Run commit

The configuration is committed.

----End

## Configuring IPv4 IS-IS Route Recursion to IPv6 Next Hops

Configuring IPv4 IS-IS route recursion to IPv6 next hops allows IPv4 routes to be forwarded on IPv6 networks, improving network compatibility.

### Context

During the evolution from IPv4 to IPv6, some IPv4 services may fail to adapt to IPv6 in a short period of time. To ensure compatibility with these IPv4 services on the IPv6 network, you can configure IPv4 route recursion to IPv6 next hops.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run isis [ process-id ]

The IS-IS view is displayed.

#### Step 3 Run ipv4-prefix ipv6-nexthop enable

IPv4 route recursion to IPv6 next hops is configured.

#### Step 4 Run commit

The configuration is committed.

----End

## Verifying the IPv4 IS-IS Route Selection Configuration

After configuring IPv4 IS-IS route selection, check the configurations.

### Procedure

- Run the **display isis route [ process-id | vpn-instance vpn-instance-name ] [ ipv4 ] [ verbose | [ level-1 | level-2 ] | ip-address [ mask | mask-length ] ]** \* command to check IS-IS routing information.

- Run the **display isis lsdb [ { level-1 | level-2 } | verbose | { local | lsp-id | is-name symbolic-name } ] \* [ process-id | vpn-instance vpn-instance-name ]** command to check information in the IS-IS LSDB.

----End

### 1.1.8.2.5 Configuring IPv4 IS-IS to Interact with Other Routing Protocols

If other routing protocols are configured on an IS-IS network, configure IS-IS to interact with these protocols for communication between them.

#### Usage Scenario

If other routing protocols are configured on an IS-IS network, note the following issues:

- Priorities of IS-IS routes

If multiple routes to the same destination are discovered by different routing protocols running on the same device, the route discovered by the protocol with the highest priority is selected. For example, if both OSPF and IS-IS are configured, the route discovered by OSPF is used because OSPF enjoys a higher priority than IS-IS by default.

If you want the route discovered by IS-IS to be preferentially selected, configure a higher priority for the route.

- Communication between areas

If other routing protocols are configured on an IS-IS network, configure IS-IS to interact with those routing protocols so that IS-IS areas can communicate with non-IS-IS areas.

#### NOTE

The LSDBs of different IS-IS processes on a device are independent of each other. Therefore, each IS-IS process on the device considers routes of the other IS-IS processes as external routes.

To ensure successful traffic forwarding, configure IS-IS to import external routes on a device (such as a Level-1-2 IS-IS router) where external routes are configured. Such configuration enables all devices in IS-IS areas to learn external routes, implementing refined control over traffic forwarding.

To ensure successful forwarding of traffic destined for IS-IS areas, enable the other routing protocols to interact with IS-IS.

#### Pre-configuration Tasks

Before configuring IPv4 IS-IS to interact with other routing protocols, complete the following tasks:

- Configure the link layer protocol on interfaces.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- Configure basic IPv4 IS-IS functions.**
- Configure basic functions of other routing protocols.

## Configuring a Preference Value for IPv4 IS-IS

If multiple routes to the same destination are discovered by different routing protocols, configure the highest priority value for IS-IS so that a route discovered by IS-IS can be selected preferentially.

### Context

If multiple routes to the same destination are discovered by different routing protocols running on the same device, the route discovered by the protocol with the highest priority is selected.

For example, if both OSPF and IS-IS are configured on a network, the route discovered by OSPF is used because OSPF has a higher priority than IS-IS by default.

You can set a preference value for IS-IS to increase the priority of IS-IS routes so that they are preferentially selected. In addition, you can configure a route-policy to increase the priority of specified IS-IS routes, without affecting route selection.

### Procedure

- Configure a preference value for IS-IS.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **isis [ process-id ]**  
The IS-IS view is displayed.
  - c. Run **preference *preference***  
The IS-IS priority value is configured.
- Configure a preference value for specified IS-IS routes.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **isis [ process-id ]**  
The IS-IS view is displayed.
  - c. Run **preference { { route-policy *route-policy-name* | route-filter *route-filter-name* } | *preference* } \***  
A preference value is configured for the matched IS-IS routes.

*preference* takes effect only on the matched IS-IS routes.

d. Run **commit**

The configuration is committed.

----End

## Configuring IPv4 IS-IS to Import External Routes

Configuring IS-IS to import external routes on a boundary device enables devices in the IS-IS domain to learn external routes and guide traffic forwarding.

### Context

After IS-IS is configured on a boundary device to advertise a default route, the traffic destined for a destination outside the domain can be diverted to the boundary device for processing. However, because other devices in the IS-IS domain do not have external routes, a large amount of traffic is forwarded to the boundary device, which overloads the boundary device.

If multiple boundary devices are deployed, optimal routes to other routing domains need to be selected. In this case, all the other devices in the IS-IS routing domain must learn all or some external routes.

Routing policies can be configured to import only the external routes that match filtering conditions or advertise only the imported routes that match filtering conditions to other IS-IS devices.

#### NOTICE

IS-IS and other dynamic routing protocols such as OSPF and BGP often import routes from each other. If no routing policy is configured or a routing policy is incorrectly configured on a device where IS-IS, OSPF, and BGP import routes from each other, a Layer 3 routing loop may occur due to a route selection result change. As a result, services are compromised. For details about the cause of the routing loop, see [Routing Loop Detection for Routes Imported to IS-IS](#).

### Procedure

- Configure IS-IS to import external routes.
  - a. Run **system-view**

The system view is displayed.
  - b. Run **isis [ process-id ]**

The IS-IS view is displayed.
  - c. Configure IS-IS to import external routes.
    - To import external routes to IS-IS and set a cost for them, run the **import-route { direct | static | unr | { ospf | rip | isis } [ process-id ] | bgp [ permit-ibgp ] } [ cost-type { external | internal } | cost cost | tag tag | route-policy route-policy-name | [ level-1 | level-2 | level-1-2 ] ] \* or import-route { ospf | isis } [ process-id ] [ cost-type { external | internal } | cost cost | tag tag | route-policy route-policy-name | [ level-1 | level-2 | level-1-2 ] | no-sid ] \* command.**

- To import external routes to IS-IS and keep the original costs, run the **import-route { { ospf | rip | isis } [ process-id ] | bgp [ permit-ibgp ] | direct } inherit-cost [ tag tag | route-policy route-policy-name | [ level-1 | level-2 | level-1-2 ] ] \* or import-route { ospf | isis } [ process-id ] inherit-cost [ { level-1 | level-2 | level-1-2 } | tag tag | route-policy route-policy-name | no-sid ] \* command.** The protocol from which routes are imported cannot be **static**.

 NOTE

IS-IS advertises all imported external routes to an IS-IS routing domain by default.

If only some imported external routes need to be advertised to the IS-IS routing domain, run the **filter-policy export** command to set a filtering policy.

d. Run **commit**

The configuration is committed.

- Configure IS-IS to advertise some external routes to an IS-IS routing domain.
  - a. Run **system-view**

The system view is displayed.

b. Run **isis [ process-id ]**

The IS-IS view is displayed.

c. Configure the device to advertise some external routes to the IS-IS routing domain.

Run any of the following commands as required:

- Based on the basic ACL:

1) Run **filter-policy { acl-number| acl-name acl-name } export [ protocol [ process-id ] ]**

The filtering policy used by IS-IS to advertise routes is configured.

2) Run **quit**

Return to the system view.

3) Run **acl { name basic-acl-name { basic | [ basic ] number basic-acl-number } | [ number ] basic-acl-number } [ match-order { config | auto } ]**

The ACL view is displayed.

4) Run **rule [ rule-id ] [ name rule-name ] { deny | permit } [ fragment-type { fragment | non-fragment | non-subseq | fragment-subseq | fragment-spe-first } | source { source-ip-address { source-wildcard | 0 | src-netmask } | any } | time-range time-name | vpn-instance vpn-instance-name ] \***

An ACL rule is configured.

When the **rule** command is used to configure a filtering rule for a named ACL, only the configurations specified by **source** and **time-range** take effect.

When a filter-policy of a routing protocol is used to filter routes:

- If the action specified in an ACL rule is **permit**, a route matching the rule will be accepted or advertised by the system.
- If the action specified in an ACL rule is **deny**, a route matching the rule will not be accepted or advertised by the system.
- If the network segment of a route is not within the range specified in an ACL rule, the route will not be accepted or advertised by the system.
- If an ACL does not contain any rules, none of the routes matched against the filter-policy that uses this ACL will be accepted or advertised by the system.
- Routes can be filtered using a blacklist or whitelist:  
If ACL rules are used for matching in configuration order, the system matches the rules in ascending order of their IDs.  
Filtering using a blacklist: Configure a rule with a smaller ID and specify the action **deny** in this rule to filter out the unwanted routes. Then, configure another rule with a larger ID in the same ACL and specify the action **permit** in this rule to accept or advertise the other routes.  
Filtering using a whitelist: Configure a rule with a smaller ID and specify the action **permit** in this rule to permit the routes to be accepted or advertised. Then, configure another rule with a larger ID in the same ACL and specify the action **deny** in this rule to filter out the unwanted routes.

- Based on an IP prefix list:

Run **filter-policy ip-prefix ip-prefix-name export** [ *protocol* [ *process-id* ] ]

- Based on a route-policy:

Run **filter-policy route-policy route-policy-name export** [ *protocol* [ *process-id* ] ]

#### NOTE

After this command is run, only external routes that meet the specified conditions can be advertised to the IS-IS routing domain.

#### d. Run **commit**

The configuration is committed.

----End

## Verifying the Configuration of Interaction Between IPv4 IS-IS and Other Routing Protocols

After configuring IS-IS to import routes from other protocols, check the configurations.

## Procedure

- Run the **display isis lsdb [ { level-1 | level-2 } | verbose | { local | lsp-id | is-name symbolic-name } ] \* [ process-id | vpn-instance vpn-instance-name ]** command to check IS-IS LSDB information.
- Run the **display isis route [ process-id | vpn-instance vpn-instance-name ] [ ipv4 ] [ verbose | [ level-1 | level-2 ] | ip-address [ mask | mask-length ] ] \*** command to check IS-IS routing information.
- Run the **display ip routing-table ip-prefix ip-prefix-name [ verbose ]** command to check the IP routing table.

----End

### 1.1.8.2.6 Adjusting the IPv4 IS-IS Route Convergence Speed

Accelerating IS-IS route convergence can improve the fault location efficiency and network reliability.

## Usage Scenario

The procedure for implementing IS-IS is as follows:

- Establishment of neighbor relationships: establishes neighbor relationships by exchanging Hello packets between two devices.
- LSP flooding: implements LSDB synchronization between devices in the same area.
- SPF calculation: uses the SPF algorithm to calculate IS-IS routes, and delivers IS-IS routes to the routing table.

To accelerate the IS-IS route convergence, configure the following parameters:

- Interval for detecting failures on IS-IS neighboring devices
- Flooding parameters of CSNPs and LSPs
- Interval for SPF calculation

You can also configure convergence priorities for IPv4 IS-IS routes so that key routes can converge first if the network topology changes, which minimizes adverse impacts on key services.

## Pre-configuration Tasks

Before adjusting the IPv4 IS-IS route convergence speed, complete the following tasks:

- Configure the link layer protocol on interfaces.
- Configure IP addresses for interfaces to ensure that neighboring nodes are reachable at the network layer.
- Configure basic IPv4 IS-IS functions.**

## Configuring the Interval for Detecting IS-IS Neighboring Device Failures

To minimize the impacts of neighboring device failures on IS-IS networks, accelerate the detection IS-IS neighboring device failures.

## Context

Connection status between an IS-IS device and its neighboring devices can be monitored by exchanging Hello packets at intervals. An IS-IS neighboring device is considered. Down if the IS-IS device does not receive any Hello packets from the neighboring device within a specified period (holding time). A failure in an IS-IS neighboring device will trigger LSP flooding and SPF calculation, after which IS-IS routes re-converge.

To adjust the fault detection speed, use the following methods to accelerate the speed of detecting neighboring device failures:

- Configure the interval at which Hello packets are sent.
- Configure the number of Hello packets that are sent before the local device considers the neighbor Down.

### NOTE

Holding time of neighboring devices = Interval at which Hello packets are sent x Number of Hello packets that are sent before the local device considers the neighbor Down. The maximum value of the holding time is 65535s.

- **Configure Dynamic BFD for IS-IS.**

### NOTE

Configuring IPv4 BFD for IS-IS is recommended because this method ensures faster fault detection than the other two methods.

## Procedure

- Set an interval at which Hello packets are sent.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **interface interface-type interface-number**  
The interface view is displayed.
  - c. Run **isis timer hello hello-interval [ level-1 | level-2 ] [ conservative ]**  
The interval at which Hello packets are sent is set.  
If the **conservative** parameter is specified in the command, the conservative mode is enabled for the holdtime of the IS-IS neighbor relationship.
    - If the parameter is specified and the holdtime of the IS-IS neighbor relationship is less than 20s, the IS-IS neighbor relationship is disconnected when the hold time elapses.
    - If the parameter is not specified and the holdtime of the IS-IS neighbor relationship is less than 20s, the IS-IS neighbor relationship is disconnected when the period of the hold time and a delay elapses.

 NOTE

A broadcast link can transmit both Level-1 and Level-2 Hello packets. You can set different intervals for these two types of Hello packets. By default, both Level-1 and Level-2 Hello packets are sent.

A P2P link can transmit only one type of Hello packets. Therefore, neither **level-1** or **level-2** needs to be specified if a P2P link is used.

The timer must be longer than the time a device takes to perform a master/slave main control board switchover. If the timer is set to less than the switchover time, a protocol intermittent interruption occurs during a switchover. The default timer value is recommended.

d. Run **commit**

The configuration is committed.

- Set the number of Hello packets that are sent before the local device considers the neighbor Down.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **isis timer holding-multiplier number [ level-1 | level-2 ]**

The number of Hello packets that are sent before the local device considers the neighbor Down is configured.

 NOTE

A broadcast link can transmit both Level-1 and Level-2 Hello packets. You can set different intervals for these two types of Hello packets. If no level is specified, the configured interval takes effect on both Level-1 and Level-2 Hello packets.

A P2P link can transmit only one type of Hello packets. Therefore, neither **level-1** or **level-2** needs to be specified if a P2P link is used.

d. Run **commit**

The configuration is committed.

----End

## Setting Flooding Parameters of SNPs and LSPs

To speed up LSDB synchronization between devices, set proper values for flooding parameters of SNPs and LSPs.

## Context

SNPs consist of CSNPs and PSNPs. CSNPs carry summaries of all LSPs in LSDBs, ensuring LSDB synchronization between neighboring routers. SNPs are processed differently on broadcast links and P2P links.

- On a broadcast link, CSNPs are periodically sent by a DIS device. If a router detects that its LSDB is not synchronized with that on its neighboring router, the router will send PSNPs to apply for missing LSPs.
- On a P2P link, CSNPs are sent only during initial establishment of neighbor relationships. If a request is acknowledged, a neighboring router will send a

PSNP in response to a CSNP. If a router detects that its LSDB is not synchronized with that on its neighboring router, the router will send PSNPs to apply for missing LSPs.

You can modify the following parameters of SNPs and LSPs on the NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X to speed up LSDB synchronization:

- **Set an interval at which CSNPs are sent.**
- **Configure the intelligent timer to control LSP generation.**
- **Set the size of an LSP.**
- **Set the LSP update interval.**
- **Set the maximum lifetime for LSPs.**
- **Set the maximum holdtime for the largest IS-IS route cost in local LSPs.**
- **Enable LSP fast flooding.**
- **Set an interval at which LSPs are retransmitted over a P2P link.**
- **Configure automatic IS-IS LSP Remaining Lifetime adjustment.**

## Procedure

- Set an interval at which CSNPs are sent.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **interface interface-type interface-number**  
The interface view is displayed.
  - c. Run **isis timer csnp csnp-interval [ level-1 | level-2 ]**  
The interval at which CSNPs are sent is set on the specified interface.
- Configure the intelligent timer to control LSP generation.
  - a. Run **system-view**  
The system view is displayed.
  - b. Run **isis [ process-id ]**  
The IS-IS view is displayed.
  - c. Run **timer lsp-generation max-interval [ init-interval [ incr-interval ] ] [ level-1 | level-2 ]**  
The intelligent timer is configured to control LSP generation.  
The intelligent timer involves three parameters, and the parameters are described as follows:
    - When only *max-interval* is used, the intelligent timer becomes a one-shot timer.

- If both *init-interval* and *incr-interval* are configured, the initial interval for generating an LSP is *init-interval*, and the interval for generating an LSP with the same LSP ID for the second time is *incr-interval*. From the third time on, each time the route changes, the interval for generating an LSP doubles until the interval reaches *max-interval*. If the local routing information still changes frequently within *max-interval*, the delay remains *max-interval*. If the local routing information does not change after the interval specified by *max-interval* expires or the IS-IS process is restarted, the interval decreases to *init-interval*.
  - If *init-interval* is specified but *incr-interval* is not specified, *init-interval* is used as the interval for generating an LSP for the first time, and *max-interval* is used as the interval for generating subsequent LSPs. If the local routing information changes frequently within the interval specified by *max-interval*, the delay remains *max-interval*. If the local routing information does not change after the interval specified by *max-interval* expires or the IS-IS process is restarted, the interval decreases to *init-interval*.
- d. Run **suppress-flapping lsp-generation timer** *delay-interval* [ **threshold** *threshold-value* ]
- A period is specified for the system to delay generating the same LSP during route flapping.
- e. Run **commit**
- The configuration is committed.
- Set the size of an LSP.
    - a. Run **system-view**
    - The system view is displayed.
    - b. Run **isis** [ *process-id* ]
    - The IS-IS view is displayed.
    - c. Run **lsp-length originate** *max-size*
    - The size of an LSP to be generated is set.
    - d. Run **lsp-length receive** *max-size*
    - The size of an LSP to be received is set.

 **NOTE**

*max-size* of an LSP to be generated must be less than or equal to *max-size* of an LSP to be received.

The value of *max-size* set using the **lsp-length** command must meet the following requirements; otherwise, the MTU status on the interface is considered down.

- The MTU of an Ethernet interface must be greater than or equal to the sum of the value of *max-size* plus 3.
- The MTU of a P2P interface must be greater than or equal to the value of *max-size*.

e. Run **commit**

The configuration is committed.

- Set the LSP update interval.

a. Run **system-view**

The system view is displayed.

b. Run **isis [ process-id ]**

The IS-IS view is displayed.

c. Run **timer lsp-refresh refresh-value**

An LSP update interval is set.

To ensure the synchronization of LSPs in the entire area, IS-IS periodically sends all the current LSPs.

 NOTE

Ensure that the LSP update interval is at least 300s shorter than the maximum LSP lifetime so that new LSPs can reach all routers in the area before the original LSPs expire.

The larger a network, the greater the deviation between the LSP update interval and the maximum LSP lifetime.

d. Run **commit**

The configuration is committed.

- Set the maximum lifetime for LSPs.

a. Run **system-view**

The system view is displayed.

b. Run **isis [ process-id ]**

The IS-IS view is displayed.

c. Run **timer lsp-max-age max-age-value**

The maximum lifetime is set for LSPs.

When a device generates the system LSP, it fills in the maximum lifetime for this LSP. The lifetime of the LSP decreases with time. If the device does not receive any updated LSPs and the lifetime of the LSP is reduced to 0, the device keeps the LSP for another 60s. If the device fails to receive any updated LSPs within the 60s, it deletes the LSP from the LSDB.

d. Run **commit**

The configuration is committed.

- Set the maximum holdtime for the largest IS-IS route cost in local LSPs.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **isis [ process-id process-id ] peer hold-max-cost timer timer**

The holdtime of the maximum cost in local IS-IS LSPs is set.

When an IS-IS interface changes from down to up, the IS-IS neighbor relationship is re-established. After IGP route convergence is completed, traffic is switched back. In most cases, IGP routes converge quickly.

However, many services that depend on IGP routes may require a delayed switchback. To achieve this, run the **isis peer hold-max-cost** command to set the holdtime for the maximum route cost (16777214 in wide cost style and 63 in narrow cost style) in local IS-IS LSPs, so that traffic is forwarded over the original path before the hold-max-cost timer expires. After the timer expires, the normal cost value is restored, and then traffic is normally switched back.

d. (Optional) Run **isis peer hold-cost cost-val timer timer-val**

The period during which IS-IS keeps the specified cost in local LSPs is set.

e. Run **commit**

The configuration is committed.

● Enable LSP fast flooding.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

c. Run **isis timer lsp-throttle throttle-interval [ count count ]**

The minimum interval at which LSPs are sent by the interface and the maximum number of LSPs that can be sent within the interval are set.

The *count* parameter specifies the maximum number of LSPs that can be sent within the interval specified by *throttle-interval*. The value is an integer ranging from 1 to 1000.

d. Run **isis [ process-id ]**

The IS-IS view is displayed.

e. Run **suppress-flapping lsp-flood timer delay-interval [ threshold threshold-value ]**

A period is specified for the system to delay LSP flooding during route flapping.

f. Run **commit**

The configuration is committed.

● Set an interval at which LSPs are retransmitted over a P2P link.

a. Run **system-view**

The system view is displayed.

b. Run **interface interface-type interface-number**

The interface view is displayed.

- c. (Optional) Run **isis circuit-type p2p [ strict-snpa-check ]**

The broadcast interface is simulated as a P2P interface.

An interval at which LSPs are retransmitted takes effect only on P2P interfaces. Therefore, to configure the interval on a broadcast interface, change the broadcast interface to a P2P interface first.

- d. Run **isis timer lsp-retransmit *retransmit-interval***

The interval at which LSPs are retransmitted over a P2P link is set.

- e. Run **commit**

The configuration is committed.

- Configure automatic IS-IS LSP Remaining Lifetime adjustment.

- a. Run **system-view**

The system view is displayed.

- b. Run **isis [ *process-id* ]**

The IS-IS view is displayed.

- c. (Optional) Run **undo lsp-remaining-lifetime refresh disable**

Automatic IS-IS LSP Remaining Lifetime adjustment is enabled.

- d. Run **lsp-remaining-lifetime refresh timer { *refreshvalue* | lsp-max-age }**

An IS-IS LSP Remaining Lifetime value is set.

- e. Run **commit**

The configuration is committed.

----End

## Adjusting the SPF Calculation Interval

By adjusting the SPF calculation interval, you can ensure that IS-IS responds to network changes in time and reduce the system resources consumed by SPF calculation.

### Context

When a network changes frequently, IS-IS performs SPF calculation frequently. Frequent SPF calculations consume a large number of CPU resources, affecting services.

The advantage of configuring an intelligent timer is that the interval for SPF calculation is short, which speeds up IS-IS route convergence. When the topology of the entire IS-IS network becomes stable, the interval between two SPF calculations is prolonged to reduce unnecessary calculations.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

**Step 2 Run `isis [ process-id ]`**

The IS-IS view is displayed.

**Step 3 Run `timer spf max-interval [ init-interval [ incr-interval ] ]`**

The SPF intelligent timer is configured.

The interval for SPF calculation is described as follows:

- The delay for the first SPF calculation is *init-interval*; the delay for the second SPF calculation is *incr-interval*. From the third time on, the SPF calculation delay doubles each time the route changes until the delay reaches *max-interval*. If network flapping persists within the interval specified by *max-interval*, the delay remains *max-interval*. If the network does not flap within *max-interval* or the IS-IS process is restarted, the delay decreases to *init-interval*.
- If *incr-interval* is not used, the delay for the first SPF calculation is *init-interval*. From the second time on, the delay remains *max-interval*. If the local routing information changes frequently within *max-interval*, the delay for SPF calculation remains *max-interval*. If the local routing information does not change within the interval specified by *max-interval* or the IS-IS process is restarted, the delay decreases to *init-interval*.
- When only *max-interval* is used, the intelligent timer becomes a one-shot timer.

**Step 4 Run `suppress-flapping route-calculate timer delay-interval [ threshold threshold-value ]`**

A period is specified for the device to delay route calculation when the device receives a purge LSP.

**Step 5 Run `timer purge-zero-lsp route-calculate-delay delay-interval`**

A period is specified for the device to delay route calculation when the device receives a purge LSP.

**Step 6 Run `commit`**

The configuration is committed.

----End

## Configuring Convergence Priorities for IPv4 IS-IS Routes

You can set a high convergence priority for key routes on an IS-IS network to ensure that these routes converge first if the network topology changes. This minimizes the impact on important services.

## Context

The NetEngine 8100 X, NetEngine 8000 X and NetEngine 8000E X allows you to configure the highest convergence priority for specific IS-IS routes so that those IS-IS routes converge first when a network topology changes.

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run isis [*process-id*]

The IS-IS view is displayed.

### Step 3 Run prefix-priority [ level-1 | level-2 ] { critical | high | medium | very-low } { ip-prefix *prefix-name* | tag *tag-value* }

A convergence priority is set for IS-IS routes.

The rules for applying the convergence priorities of IS-IS routes are as follows:

- Existing IS-IS routes converge based on the priorities configured in the **prefix-priority** command.
- New IS-IS routes that match the filtering rules converge based on the priorities configured in the **prefix-priority** command.
- If an IS-IS route meets the matching rules of multiple convergence priorities, the highest convergence priority is used.
- The convergence priority of Level-1 IS-IS routes is higher than that of Level-2 IS-IS routes.
- If no level is specified, the configuration takes effect on both Level-1 and Level-2 IS-IS routes.

#### NOTE

The **prefix-priority** command is only applicable to the public network.

After the **prefix-priority** command is run, the convergence priority of 32-bit host routes is **low**, and the convergence priorities of the other routes are specified in the **prefix-priority** command.

### Step 4 Run commit

The configuration is committed.

----End

## Enabling IS-IS Intelligent Convergence

Enabling IS-IS intelligent convergence can speed up IS-IS route convergence, thereby improving convergence performance.

## Context

In a fault-triggered switching scenario where the local device receives a route from a single node, IS-IS intelligent convergence can be enabled to allow IS-IS to perform fast route convergence by using the fast convergence algorithm. This improves convergence performance.

## Procedure

### Step 1 Run system-view

The system view is displayed.

**Step 2** Run **isis [ process-id ]**

The IS-IS view is displayed.

**Step 3** Run **intelligent-convergence enable**

IS-IS intelligent convergence is enabled.

 **NOTE**

In the same networking scenario, the convergence speeds of devices with the **intelligent-convergence enable** command configuration increase significantly, far higher than those of the devices without this command configuration. As a result, routing loops may occur. Therefore, exercise caution when you run this command.

**Step 4** Run **commit**

The configuration is committed.

----End

## Verifying the IPv4 IS-IS Route Convergence Speed Configuration

After configuring parameters to adjust the IPv4 IS-IS route convergence speed, check the configurations.

## Procedure

- Run the **display isis interface [ [ verbose | traffic-eng ] \* | tunnel ] [ process-id | vpn-instance vpn-instance-name ]** command to check IS-IS packet information.
- Run the **display isis route [ process-id | vpn-instance vpn-instance-name ] [ ipv4 ] [ topology topology-name ] [ verbose | [ level-1 | level-2 ] | ip-address [ mask | mask-length ] ] \***  command to check the priority of IS-IS routes.

----End

### 1.1.8.2.7 Configuring an IS-IS Multi-Instance Process

To reduce the interface count and configuration workload required by multiple conventional IS-IS processes, you can configure IS-IS multi-instance processes. A conventional IS-IS process and multiple IS-IS multi-instance processes can be configured on the same interface.

## Usage Scenario

On IS-IS networks, multiple IS-IS processes need to be used to isolate different access rings. To close the access rings, the IS-IS processes on all access rings need to be enabled. In this case, you need to enable different IGP processes on one interface. This reduces the interface count and configuration workload of the access rings.

## Pre-configuration Tasks

Before configuring an IS-IS multi-instance process, complete the following tasks:

- Configure a link layer protocol.
- Configure IP addresses for interfaces and ensure that neighboring devices are reachable at the network layer.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **isis [ process-id ]**

An IS-IS process is created, and its view is displayed.

*process-id* specifies the ID of an IS-IS process. If *process-id* is not specified, 1 is used as the IS-IS process ID. To associate an IS-IS process with a VPN instance, run the **isis process-id vpn-instance vpn-instance-name** command.

### Step 3 Run **multi-instance enable iid iid-value**

The IS-IS process is configured as an IS-IS multi-instance process.

### Step 4 Run **quit**

Return to the system view.

### Step 5 Run **interface interface-type interface-number**

The interface view is displayed.

### Step 6 Run the **isis enable [ process-id ]** command to enable IS-IS on the interface and associate the IS-IS process with the interface or run the **isis ipv6 enable process-id** command to enable IS-IS IPv6 on the interface and associate the IS-IS process with the interface.

### Step 7 Configure parameters for the IS-IS multi-instance process as required.

- Run the **isis process-id process-id authentication-mode** command to configure the IS-IS interface to authenticate Hello packets using the specified authentication mode and password.
- Run the **isis process-id process-id cost** command to set a link cost for the IS-IS interface.
- Run the **isis process-id process-id ipv6 cost** command to set a link cost in the IPv6 topology.
- Run the **isis process-id process-id circuit-type** command to simulate an IS-IS broadcast interface as a P2P interface.
- Run the **isis process-id process-id prefix-sid** command to configure the IP address of a loopback interface as a Segment Routing prefix segment ID (SID).

### Step 8 Run **commit**

The configuration is committed.

For details on how to configure other functions for an IS-IS process, see [Creating an IPv4 IS-IS process](#) or [Creating an IPv6 IS-IS process](#).

----End

## Checking the Configurations

After configuring an IS-IS multi-instance process, check the configurations.

- Run the **display isis interface *interface-type* *interface-number* [ verbose ]** command to check information about the IS-IS interface. The command output shows more than one IS-IS process on the interface.

### 1.1.8.2.8 Enabling the Advertisement of IPv4 Delay Information

To allow IS-IS to collect and flood information about the intra-area IPv4 link delay, you can enable the advertisement of IPv4 delay information for an IS-IS process.

## Usage Scenario

Traditional path computation algorithms compute the optimal path to a destination address based on costs. However, such a computed path may not have the minimum delay. For services that have stringent requirements on delay, path computation can be performed based on the delay rather than on the cost to ensure that service traffic is transmitted along the path with the minimum delay. To meet these requirements, enable the advertisement of IPv4 delay information for an IS-IS process. After this function is enabled, IS-IS collects and floods information about the intra-area IPv4 link delay, and BGP-LS reports the information to the controller. This allows the controller to use the delay information to compute the optimal path on the P2P network.

## Pre-configuration Tasks

Before enabling the advertisement of delay information, complete the following task:

- Configure the TWAMP Light controller to detect delay information.
- Set the network type of the IS-IS interface to P2P.**

## Procedure

### Step 1 Run system-view

The system view is displayed.

### Step 2 Run isis [ *process-id* ]

An IS-IS process is created, and the view is displayed.

*process-id* specifies an IS-IS process ID. If the *process-id* parameter is not specified, the system creates process 1 by default. To bind an IS-IS process to a VPN instance, run the **isis *process-id* vpn-instance *vpn-instance-name*** command.

### Step 3 Run cost-style { wide | wide-compatible | compatible }

A cost style is set for IS-IS.

### Step 4 (Optional) Run metric-delay normalize interval *interval-value* [ offset *offset-value* ]

The link delay normalization function is configured for the IS-IS process.

For the delay-based path computation algorithm, the delay differences of links are different, and the differences may be small. However, even if the delay differences are small, only one optimal path can be generated according to the existing SPF algorithm, and load balancing cannot be implemented within a certain delay tolerance range. As a result, link resources on the network cannot be fully utilized. To resolve this problem to the greatest extent, normalization processing may be performed on the link delays with a small difference or a difference within an acceptable range so that load balancing can be implemented and link resources on the network can be fully utilized.

You can also run the **isis [ process-id process-id-value ] metric-delay normalize interval interval-value [ offset offset-value ]** command in the IS-IS interface view to configure the link delay normalization function on an interface. If the function is configured both for an IS-IS process and an IS-IS interface, the interface's configuration takes precedence over the process's configuration. Delay variation cannot be normalized.

**Step 5** Run **traffic-eng [ level-1 | level-2 | level-1-2 ]**

TE is enabled on a specified level for the IS-IS process.

**Step 6** Run **metric-delay advertisement enable [ level-1 | level-2 | level-1-2 ]**

The advertisement of the maximum and minimum delay information is enabled.

**Step 7** Run **metric-delay average advertisement enable [ level-1 | level-2 | level-1-2 ]**

The advertisement of the average delay is enabled.

**Step 8** Run **metric-delay variation advertisement enable [ level-1 | level-2 | level-1-2 ]**

The advertisement of delay variation is enabled.

**Step 9** (Optional) Run **metric-delay suppress timer time-value percent-threshold percent-value absolute-threshold absolute-value**

Parameters used to suppress the advertisement of delay information are configured.

**Step 10** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After the configuration is complete, verify it.

- Run the **display isis interface verbose traffic-eng** command to check information about IS-IS-enabled interfaces.
- Run the **display isis traffic-eng advertisements** command to check the TE information advertised by IS-IS.

### 1.1.8.2.9 Configuring Interface MSD Advertisement (IPv4)

Interface maximum SID depth (MSD) advertisement allows IS-IS to advertise the MSD of Segment Routing (SR) interfaces.

## Usage Scenario

When calculating paths for SR-TE Policies in an SR scenario, the controller needs to determine paths and calculate binding SIDs based on the MSD advertised by an IGP. When the link MSDs of multiple interfaces on a device are different, the node MSD advertised by IS-IS is the smallest value among all link MSDs. Comparing with advertising node MSDs only, advertising link MSDs provides more accurate MSD information, allowing the controller to calculate paths more efficiently.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **segment-routing**

The SR view is displayed.

### Step 3 Run **quit**

Return to the system view.

### Step 4 Run **isis [ process-id ]**

An IS-IS process is created, and the IS-IS view is displayed.

### Step 5 Run **cost-style { wide | wide-compatible | compatible }**

An IS-IS cost style is set.

### Step 6 Run **segment-routing mpls**

SR-MPLS is enabled for IS-IS.

### Step 7 Run **link-msd advertisement enable [ level-1 | level-2 | level-1-2 ]**

Interface MSD advertisement is enabled.

### Step 8 Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After the configuration is complete, verify it.

- Run the **display isis lsdb verbose** command to check IS-IS LSDB information.
- Run the **display isis traffic-eng advertisements** command to check the TE information advertised by IS-IS.

### 1.1.8.2.10 Configuring an IS-IS Process to Advertise IPv4 Packet Loss Rates

Configuring an IS-IS process to advertise IPv4 packet loss rates helps ensure that service traffic is transmitted along the path with the lowest packet loss rate.

## Prerequisites

Before configuring an IS-IS process to advertise packet loss rates, complete the following tasks:

- Run the **cost-style** command to set the IS-IS cost style to wide, wide-compatible, or compatible.
- Run the **traffic-eng** command to enable IS-IS TE.

## Context

Traditional path computation algorithms compute the optimal path to a destination address based on costs. However, this path may not be the one with the lowest packet loss rate. For services that have stringent requirements on the packet loss rate, path computation can be performed based on packet loss rates instead of costs to ensure that service traffic is transmitted along the path with the lowest packet loss rate. Specifically, configure an IS-IS process to advertise IPv4 packet loss rates. After this function is configured, IS-IS collects and floods information about intra-area IPv4 packet loss rates, and BGP-LS reports the information to the controller. The controller then computes the optimal path on the P2P network based on the packet loss rates.

## Procedure

- Step 1** Run the **system-view** command to enter the system view.
- Step 2** Run the **isis [ process-id ]** command to create an IS-IS process and enter its view.
- Step 3** Run the **cost-style { wide | wide-compatible | compatible }** command to set an IS-IS cost style.
- Step 4** Run the **traffic-eng [ level-1 | level-2 | level-1-2 ]** command to enable IPv4 TE for a specified level of the IS-IS process.
- Step 5** Run the **metric-link-loss advertisement enable [ level-1 | level-2 | level-1-2 ]** command to configure the function of advertising IPv4 packet loss rates.
- Step 6** (Optional) Run the **metric-link-loss suppress timer *timer-value* percent-threshold *percent-value* absolute-threshold *absolute-value*** command to configure suppression parameters for packet loss rate advertisement.

### NOTE

The advertised packet loss rates may be dynamic ones measured using TWAMP Light or static ones manually configured.

The valid dynamic packet loss rates measured using TWAMP Light are advertised only to the IS-IS interface bound to the TWAMP Light test session.

After receiving packet loss rate information, IS-IS advertises and floods the information.

- Step 7** Run the **commit** command to commit the configuration.

----End

## Verifying the Configuration

After configuring the function, verify the configuration.

- Run the **display isis interface verbose traffic-eng** command to check information about IS-IS-enabled interfaces.
- Run the **display isis traffic-eng advertisements** command to check the TE information advertised by IS-IS.

### 1.1.8.2.11 Configuring LFA Link Attribute Advertisement

Configuring LFA link attribute advertisement in an IS-IS process helps collect and flood the SRLG information applied by LFA in a domain.

#### Prerequisites

Before configuring LFA link attribute advertisement, complete the following tasks:

- Run the **cost-style** command to set the IS-IS cost style to wide, wide-compatible, or compatible.

#### Context

Without the SRLG link attribute used by LFA on the remote device, the local device can only preferentially select a local link that is not in the same SRLG as the primary path when using IS-IS TI-LFA to calculate a backup path. If a remote link on the backup path is in the same SRLG as the primary path and the primary path fails, the backup path may also fail. After traffic is switched to the backup path, network traffic may be interrupted. To solve the preceding problem, you can configure the advertisement of SRLG link attribute information applied by LFA through IS-IS LSPs. When the local device uses TI-LFA to calculate a backup path, it can preferentially select a remote link that is not in the same SRLG as the local link as the backup path based on the LFA link attribute information advertised by the remote device, reducing the possibility of network traffic interruption.

#### Procedure

- Step 1 Run the **system-view** command to enter the system view.
- Step 2 Run the **isis [ process-id ]** command to create an IS-IS process and enter its view.
- Step 3 Run the **cost-style { wide | wide-compatible | compatible }** command to set an IS-IS cost style.
- Step 4 Run the **advertise link-attributes application lfa** command to configure LFA link attribute advertisement.
- Step 5 Run the **commit** command to commit the configuration.

----End

#### Verifying the Configuration

After the configuration is complete, verify it.

- Run the **display isis lsdb verbose** command to check LFA link attributes.

### 1.1.8.2.12 Configuring IS-IS Extended Prefix Attribute Advertisement (IPv4)

After IS-IS extended prefix advertisement is configured, route origin information can be advertised to the LSDB so that the device can determine the origin of received routes.

#### Context

IS-IS defines a type of extended prefix attribute (IPv4/IPv6 Extended Reachability Attribute) sub-TLVs. These sub-TLVs are used to describe the origin of advertised routes and can be advertised in IPv4, IPv6, and locator TLVs. Based on the advertised sub-TLVs, the device can determine whether the received routes are inter-domain routes or host routes.

The extended prefix attribute flag (IPv4/IPv6 Extended Reachability Attribute Flags) is a part of the extended prefix attribute sub-TLV. You can run a command to determine whether this flag is advertised.

#### Pre-configuration Tasks

Before configuring IS-IS extended prefix attribute advertisement, complete the following tasks:

- Configure the link layer protocol on interfaces.
- Configure addresses for interfaces to ensure that neighboring devices are reachable at the network layer.
- [Configure basic IPv4 IS-IS functions](#).

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **isis [ process-id ]**

An IS-IS process is created, and its view is displayed.

##### Step 3 Run **advertise prefix-attributes flags**

The IS-IS process is enabled to advertise the extended prefix attribute flag.

##### Step 4 Run **quit**

Return to the system view.

##### Step 5 (Optional) Set the N flag of the extended prefix attribute on a loopback interface in the IS-IS process to 0.

By default, if a loopback interface's route with a 32-bit subnet mask is a host route, the extended prefix N flag is set to 1. To set the extended prefix N flag to 0, perform this step.

1. Run the **interface Loopback interface-number** command to enter the loopback interface view.
2. Run the **isis enable [ process-id ]** command to enable IS-IS on the interface.

3. Run the **isis [ process-id process-id-value ] prefix-attributes node-disable** command to set the N flag of the extended prefix attribute on the loopback interface in the IS-IS process to 0.
4. Run the **quit** command to return to the system view.

#### Step 6 Run commit

The configuration is committed.

----End

### Verifying the Configuration

After the configuration is complete, run the **display isis lsdb verbose** command to view information about the extended prefix attribute flag.

#### 1.1.8.2.13 Configuring Static BFD for IS-IS

BFD can provide link fault detection featuring light load and high speed (within milliseconds). Static BFD needs to be configured.

### Usage Scenario

On IS-IS networks, IS-IS neighbors periodically send Hello packets to detect neighbor status changes. For networks that require fast convergence and zero packet loss, IS-IS is unreliable to detect link faults. To address this issue, configure BFD for IS-IS.

BFD includes static BFD and dynamic BFD. Static BFD is easy to control and flexible to deploy. To save memory and ensure the reliability of key links, implement BFD on these links. Static BFD helps detect link faults rapidly and implement fast route convergence.

To configure a static BFD session, you need to manually configure BFD session parameters, including the local and remote discriminators.

#### NOTE

BFD detects only the one-hop link between IS-IS neighbors because IS-IS establishes only one-hop neighbors.

### Procedure

#### Step 1 Run **system-view**

The system view is displayed.

#### Step 2 Run **bfd**

Global BFD is enabled on the local end.

#### Step 3 Run **quit**

Return to the system view.

#### Step 4 (Optional) To configure BFD session check for an IS-IS process, perform the following steps:

1. Run **isis [ process-id ]**  
The IS-IS view is displayed.
2. Run **bfd session-up check**

BFD session check is configured for the IS-IS process.

 NOTE

When the Layer 2 network is running normally, IS-IS neighbor relationships can be established and routes can be delivered. However, if the Layer 3 network is unreachable, upper-layer traffic loss occurs. To resolve this problem, configure BFD session check for an IS-IS process by running the **bfd session-up check** command. This ensures that an IS-IS neighbor relationship is established only when the BFD session is up on corresponding interfaces. After this function is configured, it applies only to the neighbor relationships to be established (it does not apply to existing neighbor relationships).

**Step 5** Run **interface interface-type interface-number**

The interface view is displayed.

BFD can be enabled on physical interfaces only.

**Step 6** Run **isis bfd static**

Static BFD is enabled on the interface.

**Step 7** Run **quit**

Return to the system view.

**Step 8** Run **bfd session-name bind peer-ip ip-address [ interface { interface-name | interface-type interface-number } ]**

A BFD session is bound to an interface.

If both **peer-ip** (IP address of the peer end) and **interface** (local interface) are specified, BFD only monitors a single-hop link with **interface** as the outbound interface and **peer-ip** as the next hop address.

**Step 9** Run the following commands as required:

- To set the local discriminator, run the **discriminator local descr-value** command.
- To set the remote discriminator, run the **discriminator remote descr-value** command.

 NOTE

The local discriminator of the local device must be the same as the remote discriminator of the peer device, and the remote discriminator of the local device must be the same as the local discriminator of the peer device.

**Step 10** Run **commit**

The configuration is committed.

----End

## Verifying the Configuration

After the configuration is complete, verify it.

- Run the **display isis bfd [ process-id | vpn-instance vpn-instance-name ] session { peer ip-address | all }** command to view the information about the BFD session.
- Run the **display isis interface verbose** command to view the configurations of BFD for IS-IS on an interface.

### 1.1.8.2.14 Configuring Dynamic BFD for IS-IS

BFD can provide link failure detection featuring light load and high speed (within milliseconds). With dynamic BFD, routing protocols can dynamically trigger the establishment of BFD sessions.

#### Usage Scenario

On IS-IS networks, IS-IS neighbors periodically send Hello packets to detect neighbor status changes. For networks that require fast convergence and zero packet loss, IS-IS is unreliable to detect link faults. To address this issue, configure BFD for IS-IS.

BFD includes static BFD and dynamic BFD. In dynamic BFD, BFD session establishment is triggered by routing protocols. Dynamic BFD minimizes configuration errors caused by manual operations in static BFD and is easy to configure. Therefore, dynamic BFD is applicable to networks on which all devices require BFD. Dynamic BFD helps detect link faults rapidly and implement fast route convergence.

#### Pre-configuration Tasks

Before configuring dynamic BFD for IS-IS, complete the following tasks:

#### Configuring BFD Globally

Before configuring dynamic BFD for IS-IS, you need to enable BFD globally.

#### Procedure

##### Step 1 Run **system-view**

The system view is displayed.

##### Step 2 Run **bfd**

BFD is configured globally.

##### Step 3 Run **commit**

The configuration is committed.

----End

#### Configuring BFD for an IS-IS Process

By configuring BFD for an IS-IS process, you can set parameters for dynamic BFD sessions and enable dynamic BFD for IS-IS on all IS-IS interfaces.

## Procedure

### Step 1 Run **system-view**

The system view is displayed.

### Step 2 Run **isis process-id**

The IS-IS view is displayed.

### Step 3 (Optional) Run **bfd session-up check**

BFD session check is configured for the IS-IS process.

When the Layer 2 network is running normally, IS-IS neighbor relationships can be established and routes can be delivered. However, if the Layer 3 network is unreachable, upper-layer traffic loss occurs. To resolve this problem, configure BFD session check for an IS-IS process using the **bfd session-up check** command. This ensures that an IS-IS neighbor relationship is established only when the BFD session is up on corresponding interfaces. After this function is configured, it applies only to the neighbor relationships to be established, not to existing neighbor relationships.

### Step 4 Run **bfd all-interfaces enable**

BFD is enabled for the IS-IS process to establish BFD sessions.

BFD must be enabled globally before you perform this step. If BFD is enabled globally, this step is performed, and the status of neighbors is up (or the DIS is up in the case of a broadcast network), default BFD parameters are used by all interfaces in the IS-IS process to establish BFD sessions.

### Step 5 (Optional) If you need to set BFD parameters for establishing a BFD session, run the **bfd all-interfaces { min-rx-interval receive-interval | min-tx-interval transmit-interval | detect-multiplier multiplier-value | frr-binding | tos-exp tosexp-value } \* command.**

BFD detection intervals are calculated as follows:

- Effective interval at which BFD packets are sent by the local end = MAX { Configured minimum interval at which BFD packets are sent by the local end, Configured minimum interval at which BFD packets are received by the remote end }
- Effective interval at which BFD packets are received by the local end = MAX { Configured minimum interval at which BFD packets are sent by the remote end, Configured minimum interval at which BFD packets are received by the local end }
- Effective detection interval on the local end = Effective interval at which BFD packets are received by the local end x Detection multiplier configured on the remote end

If **tos-exp tosexp-value** is specified, a priority is configured for all IS-IS BFD packets in the current process.

### Step 6 (Optional) Disable a specified interface from creating a BFD session.

After BFD is configured for an IS-IS process, all interfaces on which neighbor relationships are up in the IS-IS process create BFD sessions. If BFD is not required on specific interfaces, disable these interfaces from creating BFD sessions.

1. Run **quit**  
Return to the system view.
2. Run **interface interface-type interface-number**  
The interface view is displayed.
3. Run **isis bfd block**  
The interface is disabled from creating a BFD session.
4. Run **quit**  
Return to the system view.
5. Run **isis process-id**  
The IS-IS view is displayed.

**Step 7** (Optional) Run **bfd all-interfaces incr-cost { cost-value | max-reachable } [ wtr-value ]**

The IS-IS process is enabled to adjust the cost based on the status of an associated BFD session.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

The delay configured for an interface to restore the cost based on the BFD session status takes precedence over that configured for a process to restore the cost based on the BFD session status.

**Step 8** Run **commit**

The configuration is committed.

----End

## (Optional) Configuring BFD on a Specified Interface

You can configure dynamic BFD session parameters for a specified interface.

## Procedure

**Step 1** Run **system-view**

The system view is displayed.

**Step 2** (Optional) To configure BFD session check for an IS-IS process, perform the following steps:

1. Run **isis process-id**  
The IS-IS view is displayed.
2. Run **bfd session-up check**  
BFD session check is configured for the IS-IS process.

 NOTE

When the Layer 2 network is running normally, IS-IS neighbor relationships can be established and routes can be delivered. However, if the Layer 3 network is unreachable, upper-layer traffic loss occurs. To resolve this problem, configure BFD session check for an IS-IS process by running the **bfd session-up check** command. This ensures that an IS-IS neighbor relationship is established only when the BFD session is up on corresponding interfaces. After this function is configured, it applies only to the neighbor relationships to be established (it does not apply to existing neighbor relationships).

**Step 3** Run **interface interface-type interface-number**

The interface view is displayed.

 NOTE

An interface in this case may be a physical interface or a GRE tunnel interface. If BFD is enabled on a GRE tunnel interface, millisecond-level fault detection can be implemented for the GRE tunnel.

**Step 4** Run **isis bfd enable**

BFD is enabled for the interface to establish BFD sessions.

BFD must be enabled globally before you perform this step. If BFD is enabled globally, this step is performed, and the status of neighbors is up (or the DIS is up in the case of a broadcast network), default BFD parameters are used by this interface to establish BFD sessions.

**Step 5** (Optional) Run **isis bfd { min-rx-interval receive-interval | min-tx-interval transmit-interval | detect-multiplier multiplier-value | frr-binding | tos-exp tosexp-value } \***

Parameters used for establishing a BFD session are set.

If **tos-exp tosexp-value** is specified, a priority is configured for all IS-IS BFD packets on the current interface.

 NOTE

The BFD configurations on an interface take precedence over those of a process. That is, if BFD session parameters are configured for both a process and an interface, the parameters on the interface will be used to establish BFD sessions.

**Step 6** (Optional) Run **isis bfd incr-cost { cost-value | max-reachable } [ wtr wtr-value ]**

The interface is enabled to adjust the cost based on the status of an associated BFD session.

If the function of adjusting the cost based on the status of an associated BFD session is configured both for a process and an interface, the configuration on the interface takes precedence.

The cost restoration delay configured for BFD association on an interface takes precedence over that configured for BFD association in a process.

**Step 7** (Optional) Run **isis suppress-flapping bfd detecting-interval detecting-interval-value threshold threshold-value incr-cost cost-value wtr wtr-value**

BFD session flapping suppression is enabled on the interface.

### Step 8 Run commit

The configuration is committed.

----End

## Verifying the Configuration of Dynamic BFD for IS-IS

After configuring dynamic BFD for IS-IS, check information about the BFD session and dynamic BFD for IS-IS on an interface.

### Prerequisites

Dynamic BFD for IS-IS has been configured.

### Procedure

- Run the **display isis bfd [ process-id | vpn-instance vpn-instance-name ] session { peer ip-address | all }** command to view the information about the BFD session.
- Run the **display isis bfd [ process-id ] interface** command to view the information about BFD on an interface.

----End

### 1.1.8.2.15 Configuring Track BFD for IS-IS

Track BFD allows you to manually bind an IS-IS interface to a link-bundle BFD session by specifying a session name. This function can quickly detect link faults and prevent BFD session faults caused by faults of the board on which a trunk member interface resides.

### Procedure

#### Step 1 Run system-view

The system view is displayed.

#### Step 2 Run bfd

BFD is enabled.

#### Step 3 Run quit

Return to the system view.

#### Step 4 Run isis [ process-id ]

The IS-IS view is displayed.

#### Step 5 Run network-entity net-addr

A network entity title (NET) is configured.

#### Step 6 Run quit

Return to the system view.

**Step 7** Run **interface interface-type interface-number**

An interface is created.

**Step 8** Run **quit**

Return to the system view.

**Step 9** Run **bfd sess-name bind link-bundle [ compatible-mode ] peer-ip ip-address [ vpn-instance vpn-name ] interface interface-type interface-number source-ip ip-address**

A BFD for link-bundle session is created to detect Eth-Trunk faults, and the BFD session view is displayed.

**Step 10** Run **interface interface-type interface-number**

The interface view is displayed.

**Step 11** Run **isis enable [ process-id ]**

IS-IS is enabled on the interface.

**Step 12** Run **isis bfd track session-name bfd-session-name**

Track BFD is enabled on the interface.

**Step 13** Run **commit**

The configuration is committed.

----End

### 1.1.8.2.16 Configuring IS-IS IPv4 MT to Isolate Multicast Services from Unicast Services

On an IS-IS IPv4 network, IS-IS multi-topology (MT) improves usage of network resources by allowing services to run in multiple logical topologies.

#### Usage Scenario
